But after all, the point of moſt importance reſpecting the cultivation of the Poppy for Opium in Britain is, whether its quality be equal to that of foreign Opium. This has been fully aſcertained; not only by a druggiſt in London having agreed with Mr. Ball to give him the ſame price for what he ſhould make in the year 1795, as the foreign drug ſhould bear at that time; but by the teſtimony of ſeveral eminent medical gentlemen in London who tried it, in conſequence of the requeſt of the Society for the Encouragement of Arts, Manufactures and Commerce. Dr. Latham obſerves that in its ſenſible qualities it does not ſeem inferior to any; that it poſſeſſes the excellence of being perfectly clean, which muſt always be an advantage when given in a crude ſtate; and that probably the purified extract of the foreign would not be ſuperior to the Engliſh. Dr. Pearſon alſo reports, that he found the Engliſh Opium to be equally powerful, and to produce the ſame effects as the beſt foreign preparation of this drug. Mr. Wilſon not only found the Engliſh drug equal in point of ſtrength to the beſt extract from foreign Opium; but far ſuperior in flavour, which, in the extract is much injured by the boiling, and free from the impurities which are ſo abundant in crude foreign Opium ‡.

The manner in which this drug is collected in the Eaſt has been deſcribed long ago by Kæmpfer and others; but the moſt circumſtantial detail of it is given by Mr. Kerr, in the fifth volume of Medical Obſervations and Inquiries.

When the capſules are half grown, at ſunſet, they make two longitudinal double inciſions, paſſing from below upwards, and taking care not to penetrate the internal cavity. In Perſia, according to Kæmpfer, a five-pointed knife is uſed for this purpoſe. The inciſions are repeated every evening, until each capſule has received ſix or eight wounds: they are then allowed to ripen their ſeeds. If the wound were to be made in the heat of the day, a cicatrix would be too ſoon formed. The night-dews favour the exſiliation of the juice.

Early in the morning, old women, boys and girls collect the juice, by ſcraping it off with a ſmall iron ſcoop, and depoſit the whole in an earthen pot, where it is worked by the hand in the open ſunſhine, until it becomes of a conſiderable thickneſs. It is then formed into cakes of a globular ſhape, and about four pounds in weight, and laid into little earthen balins to be farther dried. Theſe cakes are then covered over with poppy or tobacco leaves, and thus dried until they are fit for ſale. Opium is frequently adulterated with cow-dung, the extract of the plant procured by boiling, and various other ſubſtances of which they make a ſecret ‖.

The capſules of Papaver Rhoeas, red or corn Poppy, like thoſe of the *ſaminiferum*, contain a milky juice, of a narcotic quality, but the quantity is very inconſiderable, and has not been applied to any medical purpoſe; but an extract prepared from them has been ſucceſsfully employed as a ſedative.

The flowers have ſomewhat of the ſmell of Opium, and a mucilaginous taſte, accompanied with a ſlight degree of bitterneſs. A ſyrup of theſe flowers is directed in the London Pharmacopœia, which has been thought uſeful as an anodyne and pectoral, and is therefore preſcribed in coughs and catarrhal affections. The colour is beautiful, but its virtues as a medicine ſeem to be inconſiderable §.]

8. The ſtalks of the Welch Poppy are a foot high and ſmooth. The pinnas of the leaves are deeply cut on their edges; and there are a few ſmall leaves on the ſtalk ſhaped like the lower ones. The upper part of the ſtalk is naked, and ſuſtains one large yellow flower, appearing in June, and filled with ſmall purpliſh ſeeds.

* Tranſ. Arts, vol. 14. 260 to 263. † Idem, 264.

‡ Tranſ. Arts, 14. 267 to 270. ‖ Woodville, 505.
§ Idem, 513.

[Root-

[Root-leaves on very long hairy petioles, conſiſting of two or three pairs of oval-lanceolate pinnas, deeply cut, almoſt lobed; the terminating one conſiſts of three lobes deeply cut, nearly ſmooth. Stem-leaves ſimilar on ſhort petioles; the upper ones ſeſſile. Pedunculs ſlightly hairy, bearing a ſingle pale-yellow flower, of four ovate petals, ſtriated towards the baſe[a]. Stigmas five or ſix, diſtinct. Capſule oblong, narrower at the baſe, ſomewhat beaked at the top[a].—The deſcriptions of Ray and Moriſon are chiefly tranſlated from Parkinſon. Dillenius gives Bauhin's ſynonym to the *rudicaule*.

Firſt deſcribed and figured by Parkinſon in 1640. He ſays that it grows in many places of Wales, in the valleys and fields, at the foot of the hills, and by the water ſides; about a mile from Abbar, and in the midway from Denbigh to Guider, the houſe of Sir John Guin (Wynne), as alſo near a wooden bridge over the Dee to Balam in North Wales, and in going up the hill that leads to Bangor, as alſo near Angleſea.—On the back of Snowden going from Caernarvon to Llanberris; as you aſcend the Glyder from Llanberris, &c. commonly by rivulets or on moiſt rocks; alſo beyond Pont vawr[a].

Found by Dillenius on Cheddar rocks in Somerſetſhire; and ſince about Kendal, Kirby-Lonſdale, and Winander Mere in Weſtmorland, and Holker in Lancaſhire, by Mr. Woodward and others.

9. Root perennial, compoſed of two or three ſtrong fibres as thick as a man's little finger, a foot and half long, dark brown on the outſide, full of a milky juice, which is very bitter and acrid. Leaves a foot long, cloſely covered with briſtly white hairs. Stems two feet and a half high, very rough and hairy, having leaves towards the lower part like the root-leaves, but ſmaller: the upper part is naked, and ſuſtains at the top one very large flower, of the ſame colour with the common red Poppy.

[Stigmas ſixteen. Briſtles on the ſtem ſcattered, preſſed cloſe, rough with a prominent baſe[a]. Capſule globular, ſmooth, crowned with the large ſhield of the ſtigma, having one cavity in the middle, but towards the periphery divided by incomplete partitions into cells equal in number to the number of rays in the ſtigma, and opening, not by valves, but by as many holes under the ſhield. Seeds very numerous, kidney-form, beautifully marked with longitudinal ſtreaks and little excavations in rows, of a ruſſet-bay colour, covering the incomplete partitions on both ſides[a].]

Found by Tournefort in Armenia, whence he ſent the ſeeds to the royal garden at Paris, where they ſucceeded and were diſtributed to the gardens of Holland and England. It flowers here in may. There are two or three varieties, differing in the colour of the flowers; and it is ſaid that the flower is ſometimes double, with us it is always ſingle. Tournefort ſays that the Turks eat the green heads, although they are very bitter and acrid. [Cultivated before 1714, by Mr. George London[b].]

PROPAGATION AND CULTURE.

All the ſorts of Poppy are propagated by ſeeds, but thoſe which have perennial roots, may be alſo propagated by offſets. The beſt time for ſowing the ſeeds is in September, when they will more certainly grow, and thoſe ſorts which are annual will make larger plants, and flower better, than when they are ſown in the ſpring. The beſt way is to ſow the ſeeds of the annual kinds in the places where they are to remain, and to thin the plants where they are too cloſe; thoſe of the large kinds ſhould not be left nearer to each other than a foot and a half, and the ſmaller ſorts may be allowed about half that ſpace. The culture they will require after this, is only to keep them clean from weeds.

7. Thoſe who are curious to have fine Poppies in their gardens, carefully look over their plants when they begin to flower, and cut up all thoſe plants whoſe flowers are not very double and well marked, before they open their flowers, to prevent their farina mixing with their finer flowers, which would degenerate them; and it is the not being careful of this, that cauſes the flowers to degenerate ſo frequently in many places, which is often ſuppoſed to be occaſioned by the ground.

8. The yellow Welſh Poppy requires a cool ſhady ſituation, where the plants will thrive, and produce plenty of ſeeds annually. If theſe ſeeds are permitted to ſcatter, the plants will come up better than when ſown by hand; but if they are ſown, it ſhould be always in the autumn; for the ſeeds of this, which are ſown in the ſpring, rarely ſucceed.

The beſt time to tranſplant and part the roots of this ſort is in the autumn, that the plants may be well eſtabliſhed in their new quarters, before the dry weather comes on in the ſpring.

9. The eaſtern Poppy will thrive either in ſun or ſhade, for I have ſeveral of theſe plants growing under trees, where they have thriven many years, and flower full as well as thoſe in an open ſituation, but came later in the ſeaſon. This will propagate very faſt by its roots, ſo there is no neceſſity for ſowing the ſeeds, unleſs to procure new varieties. This ſort ſhould be tranſplanted at the ſame ſeaſon as the former; and if the ſeeds are ſown, it ſhould be at the ſame time, for the reaſons before given.

[5. The quantity of Scarlet Poppy, Canker or Redweed in ſome lands is a diſgrace to the farmer, and the briſſiancy of the flowers proclaims his diſgrace to the whole country. Being an annual weed it is eaſily deſtroyed by good huſbandry; but like other oily ſeeds it will lie long in the ground without corrupting. It is ſaid to have vegetated after having been twenty-four years buried.

Swine are frequently turned upon it in Norfolk; and they will eat out this troubleſome weed, with little or no damage to the wheat[b]. Others feed firſt with ſheep, then with cattle; till april, taking them off when it rains much, if the land is not very light.

Upon dry ſoils, which are moſt ſubject to Poppy, Mr. Elliman of Shoreham, ploughs his tare and rape land for wheat, the beginning or middle of ſeptember, in order to ſow the middle of octoober; the harrowing kills the Poppy; and in putting in the ſeed, he likes to tread much with oxen or ſheep. A neighbour treads his with oxen in march, which he thinks better againſt the Poppy, than doing it at ſowing[c].—This treading may deſtroy the preſent crop of Poppy; but the hoard of ſeed remains in the ground to come up on every ploughing. The only way to deſtroy ſuch weeds effectually, is to make them germinate, by bringing them near the ſurface, and then to cut and tear them with the plough, the ſkim, the ſcuffler, or the harrow, according to circumſtances.

7. Mr. Ball adviſes the ſeed of *Papaver ſomniferum*, officinal or garden Poppy to be ſown at the end of february, and again the ſecond week in march, in beds three feet and a half wide, well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine, either in ſmall drills, three in each bed, or broadcaſt; in both caſes, thinning out the plants to the diſtance of a foot from each other, when about two inches high: keep them free from weeds, and they will grow well, produce from four to ten heads, and ſhow large flowers of different colours. With an inſtrument ſomething like a rake, but with three teeth, the drills may be made at once. Poppies do not bear tranſplanting: out of four thouſand which Mr. Ball tranſplanted, not one plant came to perfection[d].

The culture as practiſed in the province of Bahar is as follows. The field being well prepared by the plough and harrow, and reduced to an exact level ſurface, it is then divided into quadrangular areæ, ſeven feet in length, and five in breadth, leaving two feet of interval, which is raiſed five or ſix inches, and hollowed out for conveying water to every area, for which purpoſe they have a well in every cultivated field. The ſeeds are ſown in octoober or november. The plants are allowed to grow ſix or eight inches

diſtant

diſtant from each other, and are plentifully ſupplied with water. When the young plants are ſix or eight inches high they are watered more ſparingly; but a compoſt of aſhes, human excrement, cow-dung, and a portion of nitrous earth ſcraped from the high-ways and old mud walls, is ſtrewed all over the beds. When the plants are near flowering, they are watered profuſely to increaſe the juice. The capſules being half grown, and fit to collect Opium from, the plants are no longer watered *.

MALE flowers in whorls, forming ſpikes. *Cal.* two-valved. *Cor.* two-valved, larger than the calyx. *Filaments* forty.

FEM. flowers ſolitary in each whorl. *Cal.* two-valved. *Cor.* two-valved, leſs than the calyx. *Stigmas* two. *Seed* three-cornered, incloſed.

SPECIES.

1. Pariana campeſtris.

Aubl. pl. gui. p. 877. *Lin. ſyſt. Gmel. p.* 828.

DESCRIPTION, *&c.*

This plant puts forth ſeveral ſtraight ſhoots or canes about one or two feet high. At each joint they are garniſhed with alternate, oval, weak leaves, ſtriated throughout their whole length, ſmooth, gloſſy, greeniſh above, paler beneath: the footſtalks are ſhort, and accompanied by a long ſplit ſheath in oppoſite directions on each ſide the ſtalk. This ſheath envelopes the ſtem from one joint to the other. It is crowned with reddiſh, long, and roughiſh hairs: this crown has on each ſide two appendices in the form of an ear, bordered on both ſides with ſimilar hairs. The ſtem is terminated by a ſerrated ſpike, formed of ſeveral ranges of male flowers growing above each other. The female flower is ſingle in the middle of each range. The ſpike of flowers is about two inches and a half in length.

This plant grows in woods in the iſle of Cayenne.]

PARIETARIA. (*From its place of growth*, Paries, *a wall.*)

Leaves elliptic acuminate, ſomewhat triple-nerved, ſtem arboreous.

DESCRIPTIONS, *&c.*

1. This reſembles our common Pellitory, but is more naked. Leaves lanceolate, drawn out to a much longer point, three-nerved, naked. The balls of flowers are ſmaller, except the bractes, which are awl-ſhaped not ovate. Styles longer. Fruits ſeſſile, grooved.—Native of the Eaſt Indies[a].

2. Root perennial, ſomewhat woody, red, fibrous; according to Lightfoot, creeping. Stems ſeveral, nearly upright, from nine inches to a foot or more in height, very much branched, round, ſtriated, ſolid, reddiſh, pubeſcent; according to Lightfoot, rough to the touch and adheſive. Leaves alternate, ovate, pointed, tapering towards each extremity, entire at the edge, ſpreading, pubeſcent along the edge and on the veins of the under ſide, on the upper ſide deep green, ſhining, ſomewhat wrinkled, and having ſmall prominent points ſcattered over it. Petioles nearly as long as the leaf is broad, pubeſcent, channelled above. Flowers ſmall, greeniſh, rough, ſeſſile, growing in balls or cluſters in the axils of the leaves; two hermaphrodites and one female in an involucre of ſeven leaves (ſix only, according to Linneus), permanent; the leaves ovate, pointed, flat, hirſute, the hairs glandular at the extremities. The hermaphrodite flowers may be diſtinguiſhed by the four ſtamens, which on the ſhedding of the pollen fly back with elaſtic force; the filaments are white and wrinkled tranſverſely; the anthers ovate, obtuſe, double; with a white pollen. Germ green, ſhining, naked; ſtigma forming a bright ſcarlet ruſt. The female is known by its ſituation between the two others, and by its want of ſtamens: the ſtigma is ſomewhat larger, and bent a little down.

To obtain a perfect idea of the manner in which the fructification is carried on, in this plant, the flowers ſhould be examined at a very early period of their expanſion; we ſhall then find in each involucre three red ſtigmas, the two outermoſt of which belong to hermaphrodite flowers, whoſe ſtamens are not yet viſible; the middle one, which is largeſt and moſt conſpicuous, to the female. If a view be taken of the ſame flowers at the time that the elaſtic filaments by their ſudden expanſion are ſcattering the pollen, the ſtyles and ſtigmas of the hermaphrodite flowers, viſible before, will often be found wanting, and the germ left naked in the centre of the flower: at this period, the ſegments of the calyx in the ſame flowers are nearly of the ſame length as the filaments, the ſtyle and ſtigma of the female flower remain perfect, and the germ is cloſely ſurrounded by a green hairy calyx, which never expands: the period of flowering being now over, a conſiderable alteration takes place in the calyx of the hermaphrodite flowers, each is conſiderably elongated, becomes more tubular, aſſumes a redder colour, has its tip preſſed down, and ſoon drops out of the involucre, in which it leaves no appearance of a ſeed; but on opening them, a ſeed will be found at the bottom of each, perfectly ſimilar to that produced by, and incloſed in the calyx of the female flower, which does not enlarge as the other does, but partaking more the nature of a capſule, on preſſure, divides at top into four parts, and contains a blackiſh, ſhining ſeed.

The manner in which the flowers ſhed their pollen is curious. The filaments, on their firſt appearance, all bend inwards; as ſoon as the pollen is arrived at a proper ſtate to be diſcharged, the warmth of the ſun, or the leaſt touch from the point of a pin, will make them inſtantly fly back, and diſcharge a little cloud of duſt. This proceſs is beſt ſeen in a morning, when the ſun ſhines on the plant in july or auguſt: if the plant be large, numbers will be ſeen exploding at the ſame inſtant[a].

Mr. Miller is ſingular in aſſerting that the Parietaria officinalis of Linneus] grows naturally in Germany and Holland, but was not in England till the year 1727, when he introduced it. [He makes our plant to be the *P. judaica* of Linneus, and the *P. minor ocimi folio* of Caſpar Bauhin. In this opinion, ſays Mr. Curtis, there is the greateſt reaſon to ſuppoſe that Mr. Miller is deceived.—It frequently happens that the plant which is common in one country is ſuppoſed to be the common plant of other countries, without examination. I do not know that it is the caſe in this inſtance. The figures of Dodonæus and Matthiolus, from which thoſe of Ger. emac. and Parkinſon are copied, are much fuller of leaves than our plant, and the ſtem is repreſented with ſtiff hairs ſtanding out. The deſcription of Pollich agrees very well with our plant, except that I do not remember the leaves to be ſo large as he deſcribes them, namely two inches and a half; but then he includes the petiole, which is more than half an inch long.

Parietary, corrupted into Pellitory, is abſurdly called Pellitory of the wall, being found on walls or among rubbiſh. It is a native of moſt parts of Europe, except the moſt northerly; in Sweden it is not found,

[a] Linn. mant.

[a] Curtis.

but it is in Denmark. Mr. Curtis remarks, that the ſame degree of cold (about 31° of Fahrenheit's thermometer) which ſtripped the Mulberry of moſt of its leaves, deſtroyed the greateſt part of the herbage of this plant.—In the autumn of 1798, Fahrenheit's thermometer being at 46° (in the houſe) on October the 13th the leaves of Mulberry, Walnut and Aſh were completely fetched off by froſt, and the herbage of Balm of Gilead cut down to the ground.

Parietary promiſes little from its ſenſible qualities: it has no ſmell, and its taſte is ſimply herbaceous. Formerly it was accounted emollient, but not being mucilaginous, this effect ought rather to be aſcribed to the warm water. Its character as a diuretic is better known. Matthiolus tells us, that the expreſſed juice, ſweetened with ſugar, had a very powerful effect in this way: and Barbeirac informs us, that a decoction of this plant, and Uva urſi, was found of great uſe in clearing the urinary paſſages of viſcid mucus, and ſabulous concretions [a]. Mr. Sole, of Bath, has obſerved remarkably good effects from the juice of this herb in dropſical caſes, in which other diuretics had failed; he converts the juice into a thin ſyrup, and gives two table ſpoonfuls thrice a day [b].

Tournefort, in his hiſtory of plants about Paris, ſays that the ſyrup gives great relief in hydropic caſes.

Dr. Stokes ſays, he has been informed, that this herb, as well as *Nitraria*, contains a conſiderable quantity of nitre; and that in making an extract from it, the maſs has taken fire.

It is recommended by Bradley to be laid on corn in granaries, for the purpoſe of driving away the weevil.]

3. This differs from the former in having ſhorter ſtalks, and ſmaller oval leaves. The flowers are alſo leſs, and in ſmaller cluſters. In other reſpects they are the ſame.

[The little balls of flowers are on the branches, ſcarcely any on the ſtem. There are two male flowers, which are tubular, cylindrical, with the teeth of the mouth converging. The female flower between them is ovate [c].

According to Gærtner there are two hermaphrodite flowers and one female flower within a ſix-leaved involucre. The calyx when ripe is cloſed, looſely embracing and concealing the ſeed. Receptacle none, except a very ſmall tubercle at the baſe of the ſeed, by which it is connected with the bottom of the calyx, as by a pedicel. Seed ovate, narrowing upwards, compreſſed like a lens, ſmooth, ſhining, dark, having a little white umbilical papilla at the baſe.

Ray believes Parietaria minor Ocimi folio *Bauh. pin.* and Parietaria exigua of Tragus, to be nothing more than a variety of the preceding: but in his Supplement he ſeems to think them different [d].

Native of Switzerland, the South of France, Sicily, Germany about Goettingen, and of Paleſtine.

4. Boccone ſays, that this differs from that of Tragus, and from the common ſort of Matthiolus only in the leaves, which are much ſmaller, the form and ſize of Chickweed: but Tournefort ſays it is an annual plant, and the ſame with his *Par. luſitanica*, which he found in Portugal, near Lamego upon the Douro.

Ray informs us, that in a ſpecimen of the Portugueze plant ſhown him by Sherard, the leaves were ſhorter in proportion to their ſize and rounder than in the common ſort. He found the Sicilian plants in ſeveral parts of Sicily; but does not ſeem to have been aware that they were the ſame. Boccone ſays it is very common in that iſland.

In the Kew catalogue it is ſaid to be a native of Spain and Portugal, without any mention of Sicily; to have been introduced in 1771, by Monſ. Richard; and to flower in july.

5. This is a very branching plant, with ſmall leaves, much reſembling thoſe of the Nettle.—Found by Monſ. Thouin in the iſle of Bourbon [e].

6. Found by Tournefort in the iſland of Crete or Candia.

7. Found at the Cape of Good Hope by Thunberg.

8. Native of New Zealand.

9. Stem herbaceous, perennial, a foot and half high, manifold, ſlender. Leaves acute, quite entire, ſmall, oppoſite, having ſmaller ones mixed with them. Flowers axillary in whorls, in ſmall cluſters or balls, male and female together without any hermaphrodites. Seed roundiſh, incloſed within the converging calyx.

Native of China and Cochinchina. It attracts the worms that infeſt ſalted fiſh or fleſh; the natives hang the plant at the mouth of their caſks, and the inſects get into it of their own accord. It is alſo eſteemed by them to be emollient, refrigerant and diuretic.

10. This is an upright ſoft ſhrub, the height of a man. Root woody, branched, fibrous, rufeſcent. Stem woody, upright, round, the bark full of chinks, aſh-coloured. Branches and branchlets alternate, ſpreading, villoſe, pithy. Shoots red, very villoſe with hoary hairs. Leaves alternate, ſpreading, entire, nerved, three-nerved above the baſe, veined: nerves and veins prominent underneath, grooved above, ſomewhat wrinkled, the younger ones very much ſo, underneath villoſe ſoft, above bright green, ſcarcely paler beneath, from four to ſix inches long, and from two to four inches wide. Petioles cylindrical, one-ſtreaked, red, very villoſe, longer than half the leaf. Panicle terminating, erect, compoſed of ſimple ſpikes, leafy, hoary-villoſe, three inches long. Spikes axillary, erect, ſeſſile, ſolitary, bracted, villoſe. Flowers commonly three, cluſtered, from the axil of each bracte, ſeſſile, in the male yellow, in the female red herbaceous. Bracte linear-lanceolate, acute, villoſe, longer than the flowers, eſpecially in the female. According to L'Heritier, the male and female flowers are on different plants. What he calls males are imperfect hermaphrodites. In theſe, he ſays, the perianth is ſix-parted; in the female, ſix or ſeven-leaved, or one-leafed cloven into ſo many parts; the germ between two nectaries, which are two roundiſh-four-cornered bodies, very ſhortly acuminate, oppoſite by the ſide of the germ, and without obſerving accurately might be taken for germs [f]: (and probably are ſo, if we may conjecture from analogy.)

Native of the Canary iſlands, where it was found by Maſſon. Introduced in 1779. It flowers from february to may [g]. L'Heritier ſays, in autumn or early in ſpring; that the male flowered at Kew, and the female at Paris. He firſt made it an Urtica, but afterwards removed it into this genus.]

PROPAGATION AND CULTURE.

The common European Pellitories may be propagated in plenty from the ſeeds. If theſe be permitted to ſcatter they will fill the ground with young plants. They are difficult to collect, being thrown out of their covers as ſoon as ripe. Having little beauty, theſe plants are ſeldom cultivated.

[10. Tree Pellitory may be increaſed by cuttings, and muſt have the protection of the green-houſe: as muſt alſo the ſeventh. The firſt, fifth, eighth and ninth muſt be kept in the ſtove.

DESCRIPTION, *&c.*

[Few plants are more readily diſtinguiſhed than this, by the proportion and regularity of all the parts. Stalk quite ſimple or unbranched, upright, ſmooth, round, naked. Leaves four, in a croſs, or a ſort of whorl, ſpreading, ſeſſile at the top of the ſtalk, ovate, quite entire, drawn to a point, ſmooth, nerved underneath, three or four inches long, and two wide. Peduncle ſingle, riſing from the middle of the four leaves, ſomewhat angular, about an inch in length, ſupporting one greeniſh flower, an inch in diameter. Calycine leaflets four, linear-lanceolate, acute, reflex. Petals alſo four, very narrow, reflex, a little ſhorter than the calyx. Stamens eight. Anthers in the middle of the filament. Styles four, three times ſhorter than the ſtamens[s]: hardly ſo long as the berry, purpliſh black[t]. Berry one, black, large, flatted at top, obſcurely four-grooved, ſmooth, juicy, and containing in each cell ſix or eight ſeeds. Root perennial, fleſhy.

The regular number in this plant is four, or ſome aliquot part or multiple of that number. There are however ſometimes only three leaves, and they are even ſaid to vary from one to ſeven. The calyx alſo has ſometimes three leaves.

The leaves and berries are ſaid to partake of the properties of Opium; and the juice of the latter to be uſeful in inflammations of the eyes. Linneus ſays the root will vomit as well as Ipecacuanha, given in a double quantity[u].

This is a ſuſpicious plant, which has nevertheleſs been uſed in medicine. Bergius recommends the herb for diſcuſſing buboes and other inflammatory tumours, in the whooping or convulſive cough, &c. Geſner experienced it to be an antidote to the poiſon of the Nux vomica. Having given a ſcruple of it to two dogs, he gave one a dram of the Paris, and it recovered; the other died. He alſo took a dram of the herb himſelf, without any effect except a dryneſs in the fauces, and ſome ſweat. Burghard on the contrary ſays, that cardialgia and vomiting enſues from the uſe of it; and Krocker was credibly informed, that a child died by eating the berries, and that another was recovered with difficulty. Geſner affirms that the berries are baneful to poultry. It ought therefore to be given with great caution. One ſcruple is given twice a day.

Herb Paris is a native of moſt countries of Europe, particularly the northern parts; and alſo of Japan. In Britain it is not uncommon, in woods, eſpecially thoſe which are thick, and on ſtrong ſoil. Gerarde ſays, it grows plentifully in Chalkney-wood, near Wakes Colne in Eſſex, in the parſonage orchard at Radwinter, and in Bocking-park by Braintree in the ſame county; in the wood near Robin Hood's well, near Nottingham; in the moor by Canterbury, called the Clapper; in Blackburne at Merton in Lancaſhire; in Dingley-wood, ſix miles from Preſton in Aunderneſſe; at Heſſet in Lancaſhire; and in Cotting-wood in the North of England, as that excellent, painful, and diligent phyſician Mr. Doctor Turner, of late memory, doth record in his Herbal.

Parkinſon, in 1640, ſays it was then loſt in the above places, "every one running thereunto, that is next him, and gathering it." He informs us that it was found in his time in Hinbury-wood, three miles from Maidſtone in Kent, in a wood called Harwarſh, near Pinnenden-heath, by Maidſtone, in Long-wood by Chiſelhurſt, and in the next called Iſeets-wood, and in a wood over againſt Boxly-abbey near Maidſtone.

Mr. Newton found it in the long Spring by Petſebogs at Chiſelhurſt; and Mr. Ray in Lampit-grove, at Notley, Eſſex.

Mr. Charles Miller diſcovered it in a little wood, not far from Hampſtead, and yet Mr. Curtis has not introduced this curious plant in his valuable Flora Londinenſis. Mr. Blackſtone, in Hanging-wood, near Harefield, Middleſex. Mr. Abbot at Hawnes, Renhold and Clapham, Park-wood in Bedfordſhire. In Kingſton, Everſden, and Wood-Ditton woods, Cambridgeſhire. In Love-lane near Derby, by Mr. Whately. At Selborne in Hampſhire by Mr. White. Ripton-wood in Huntingdonſhire by Mr. Woodward. Byfeing-wood, in Kent. In Hollinghall, Stocking and Okeley-wood in Leiceſterſhire, by Dr. Pulteney. Norfolk, by Mr. Woodward, but rare. In Brampton, Cranſley and Hardwick woods, and Whittleborough-foreſt, in Northamptonſhire, by Morton. In Aſply and Colwick woods, Nottinghamſhire, by Deering. In Headington-Wick-copſe, Oxfordſhire, by Dr. Sibthorp. In the wood near the Devil's Den near Cliſton upon Teme, woods on the ſides of Breedon-hill, and about Frankly, in Worceſterſhire. Near Gainford and in Raby-park, by Mr. Robſon. In Scotland, in a wood a mile to the ſouth of Newbottle, near Dalkeith, by Dr. Parſons. In the Den of Bethaick, four miles from Perth, by Mr. Lightfoot. In the wood of Methven, Perthſhire, by Mr. Millar. It flowers in may.]

PROPAGATION AND CULTURE.

This plant is with great difficulty preſerved in gardens. Take up the plants from the places where they grow wild, preſerving good balls of earth to their roots, and plant them in a ſhady moiſt border, where they may remain undiſturbed.

DESCRIPTION, *&c.*

[This is a small tree, with a trunk ten or twelve feet high, unarmed, even: branches long, subdivided, flexuose, prickly, ſtrict. Prickles two oppoſite at the ſides of the petioles, one between them three times as long as the others, awl-ſhaped, upright. Leaves alternate, in fours from the ſame bud, pinnate, very long, linear. General petioles linear, thicker at the baſe, flat, ſomewhat convex, ſpreading, very ſmooth. Leaflets extremely ſmall, on very ſhort petioles, ovate, ſmooth. Racemes terminating and axillary, ſolitary, ſhorter than the leaves, erect, (eight to ten) many-flowered: flowers alternate, ſcattered, yellow, on long peduncles. Calyx five-leaved, inſerted into a bell-ſhaped receptacle. Four of the petals ovate, with ſhort claws; the fifth or uppermoſt as it were pedicelled, roundiſh, with blood-red ſtreaks at the baſe: all waved and curled. Filaments ſhorter by half than the petals, equal. Anthers purple. Style ſhort, awl-ſhaped, a little aſcending. Seeds brown ſmooth [a].

Jacquin deſcribes it as a very elegant tree, with the bark both of trunk and branches remaining a long time green and ſhining, but when the tree grows old, becoming browniſh and ſtreaked. The wood is white. The prickles are ſolitary, awl-ſhaped, ſubaxillary, acuminate, ſlightly recurved, four lines in length; on the older branches frequently by threes, the middle one very ſtrong and nine lines in length. Leaves ſhining, three, four, or five from the ſame axil, on a midrib a foot long, broad and flatted. Leaflets oblong, numerous. Racemes looſe, ſimple, ſmooth, containing about ten flowers; which ſmell very ſweet, and are yellow with the uppermoſt petal variegated at the baſe with ſcarlet ſpots. Legumes yelloviſh brown, containing from one to ſix ſhining ſeeds. Parkinſonia ſeems to be diſtinguiſhed from Poinciana merely by the equality of the calycine ſegments. Theſe two trees ſown very thick make moſt beautiful hedges. Parkinſonia flowers the firſt year from ſeed, and grows very faſt.—In Jamaica it is called *Jeruſalem Thorn*. It was firſt introduced there from the main, but now grows wild in many parts and in the other iſlands of the Weſt Indies, where it was originally cultivated for incloſures. It ſeldom riſes above eight feet in height, and is well ſupplied with ſtrong thorns on every part. The branches are flexile and ſmall, and the trunk ſeldom grows to any conſiderable thickneſs [b].

The French, in the Weſt Indies, call it *Genet epineux*. It flowers ſeveral times in the year, and at the ſame time bears ripe fruit [c]. Mr. Miller cultivated it here in 1739 [d].]

He gives it the height of twenty feet, which is nearly twice as much as authors of the beſt credit attribute to it. It bears, ſays he, long ſlender bunches of yellow flowers, hanging down like thoſe of Laburnum: they perfume the air to a conſiderable diſtance, for which reaſon the inhabitants of the Weſt Indies plant them about their houſes.

PROPAGATION AND CULTURE.

This plant is propagated by ſeeds, which ſhould be ſown in ſmall pots filled with light freſh earth early in the ſpring, and the pots muſt be plunged into a hot-bed of tanner's bark, where, in three weeks or a month's time, the plants will come up, when they ſhould be kept clear from weeds, and frequently refreſhed with a little water. In a little time theſe plants will be fit to tranſplant, which ſhould be done very carefully, ſo as not to injure their roots. They muſt be each planted into a ſeparate halfpenny pot filled with light freſh earth, and then plunged into the hot-bed again, obſerving to ſtir up the tan; and if it has loſt its heat, there ſhould be ſome freſh tan added to renew it again. Then ſhade the plants from the heat of the ſun, until they have taken new root; after which time they ſhould have freſh air admitted to them every day, in proportion to the warmth of the ſeaſon. With this management the plants will grow ſo faſt, as to fill the pots with their roots by the beginning of july, at which time they ſhould be ſhifted into pots a little larger than the former, and plunged again into the bark-bed to forward their taking new root; after which it will be the beſt way to inure the plants by degrees to bear the open air, that they may be hardened before winter; for if they are kept too warm in winter, the plants will decay before the next ſpring. The only method by which I have ſucceeded in keeping theſe plants through the winter, was by hardening them in july and auguſt to bear the open air; and in ſeptember I placed them on ſhelves in the dry ſtove, at the greateſt diſtance from the fire, ſo that they were in a very temperate warmth; and there they retained their leaves all the winter, and continued in health, when thoſe which were placed in a warmer ſituation, as alſo thoſe in the greenhouſe, were entirely deſtroyed, but theſe ſeldom ſurvived the ſecond winter.

[Jacquin obſerves, that the ſeeds continue fertile ſeveral years, and germinate readily in the European ſtoves; that the plants grow luxuriantly to three feet in height the firſt year, but ſeldom live through the winter, or if they do, they die without flowering the ſecond ſummer. I have not heard that Parkinſonia has ever flowered in Europe.]

Parnaſſia with a double flower.

DESCRIPTION, *&c.*

[Root perennial, ſmall, whitiſh, fibrous; putting forth ſeveral ſtems and leaves in tufts. Stems erect, unbranched, ſomewhat twiſted, having five ſharp corners, a ſpan high, ſlender, ſmooth, having only a ſingle embracing leaf below the middle, and a ſingle flower at the top. Root-leaves petioled, ovate, pointed, quite entire, bright green above, underneath cinereous, ſmooth, netted, nine lines long, ſix or ſeven lines wide. Petioles grooved above and an inch and half long. Corolla near an inch in diameter: petals a little ſcalloped at the edges, ſlightly emarginate, white with ſemitranſparent grayiſh veins. Nectaries green, the globules yellow, from ten to fifteen, generally thirteen. Stamens only half as long as the petals, at firſt not longer than the germ, but each in order becomes longer than the reſt, as it ſheds its pollen on the orifice of the germ, which cloſes as ſoon as all the anthers have ſhed their pollen[a]. Linneus alſo obſerves, that whilſt this plant is in flower, the germ is open at the top, that the ſtamens lay their anthers alternately upon the orifice, and having diſcharged their pollen, recede to the petals. The elegant nectaries, terminated by threads, each tipt with a little yellow pellucid ſphere, ſufficiently diſtinguiſh this plant. Capſule ovate-globular, terminated by the four reflex ſtigmas, obſoletely four-grooved, one-celled or incompletely four-celled, four-valved. Receptacles four, ſpongy, oblong, narrow. Seeds irregular like ſaw-duſt, with an oblong turgid nucleus in the middle, and ſurrounded with a membranaceous rim at the ſide, of a ruſſet colour[b].

Parnaſſia is a native of moſt parts of Europe, by the ſide of bogs and moors, and in wet meadows. In Britain, it is common in Scotland, Wales, the northern counties of England, Norfolk, Staffordſhire and Worceſterſhire.] It does not grow, ſays Mr. Miller, in the neighbourhood of London, any nearer than the other ſide of Watford, in the low meadows by Caſſioberry, where it is in pretty great plenty. [We may ſuppoſe that Mr. Miller is right, ſince ſo remarkable a plant could not well have eſcaped Mr. Curtis, and it is not found in Dr. Milne's indigenous botany. It grows however near Hareſield in Middleſex, according to Mr. Blackſtone; about Ongar in Eſſex; on Hinton, Teverſham, and Trumpington moors, and near Linton in Cambridgeſhire; on Stevington, Turvey and Amptehill bogs in Bedfordſhire; in peat-bogs on Bullington-green, and under Headington-wick copſe, in Oxfordſhire; near Buddon-wood in Leiceſterſhire; about Rowel and Thorp in Northamptonſhire; at Baſford Scottum, and Papplewick in Nottinghamſhire.—Old Gerarde notices its being found in the moor near Linton in Cambridgeſhire, at Heſſet in Suffolk, at a place named Drinkſtone, in Butcher's mead; plentifully in Lanſdall and Craven in Yorkſhire, at Doncaſter, and in Thornton-fields in the ſame county. Mr. Goodyer found it in the boggy ground below the red well of Wellingborough in Northamptonſhire; and Mr. William Broad obſerved it plentifully in the Caſtle-fields of Berwick upon Tweed[c]. Parkinſon alſo notices its growing at Linton in Cambridgeſhire, Heſſet and Drinkſtone in Suffolk, in the great field of Headington near Oxford, and on the other ſide of Oxford, in the paſture next to Botley, in the high way; and at the bottom of Barton-hills in Bedfordſhire. Merret found it with a double flower in Lancaſhire; and Mr. Wood about Edinburgh[d]. It flowers in July and auguſt.]

[a] Withering. Pollich. [b] Gærtner. [c] Ger. emac. [d] Ray's ſyn.

PROPAGATION AND CULTURE.

This plant may be taken up from the natural place of growth, with balls of earth to the roots, and planted in pots filled with pretty ſtrong, freſh undunged earth, and placed in a ſhady ſituation, where, if they are conſtantly watered in dry weather, they will thrive very well, and flower every ſummer; but if the plants are planted in the full ground, it ſhould be in a very moiſt ſhady border, otherwiſe they will not live; and theſe ſhould be as duly watered as thoſe in the pots in dry weather, to make them produce ſtrong flowers.

They may be propagated by parting their roots, which ſhould be done in march, before they put out new leaves; but the roots ſhould not be divided too ſmall, for that will prevent their flowering the following ſummer. Theſe roots ſhould always be planted in pretty ſtrong freſh earth, for they will not thrive in a light rich ſoil. In the ſpring they muſt be conſtantly watered, if the ſeaſon ſhould prove dry, otherwiſe they will not flower; nor ſhould they be parted oftener than every third year, to have them ſtrong. Theſe plants flower in july, and their ſeeds are ripe the latter end of auguſt.

Leaves ovate ernate.

DESCRIPTIONS, &c.

1. This is an annual plant, growing wild in great plenty in the iſland of Jamaica, where it is called *Wild Wormwood*. [It thrives very luxuriantly about all the ſettlements in the low lands. It is obſerved to have much the ſame qualities with Feverfew; and may be uſed, like that, in reſolutive baths and infuſions[b]. It was cultivated in 1739, by Mr. Miller, and flowers here in july and auguſt[c].]

2. This is a perennial plant, which dies to the ground every autumn, and ſhoots up again the following ſpring. [Height three feet and more, with thick, round, fleſhy ſtems. Leaves half-embracing, ſinuſute, not hairy, ſomewhat paler underneath, reſembling thoſe of Inula Helenium, with frequent oblique veins or nerves: root-leaves larger and longer, on keeled petioles. The flowers grow in a corymb at the ends of the ſtem and branches: the heads are ſnow-white above, like thoſe of Gnaphalium, whitiſh green below, villoſe at firſt. The florets are white, and much larger than in the firſt ſpecies[a]. Receptacle conical, ſhort, very narrow, ſo that it is almoſt awl-ſhaped, covered with diſform chaffs: thoſe of the ray five, very much like the calycine leaflets, and alternating with them, roundiſh, concave, having within one female and two androgynous florets placed by the ſide of the female, and each covered in front by its own chaff, which is linear-acuminate; in the diſk the chaffs are very numerous, oblong, widening upwards, keeled, emarginate at the end, and ſcurfy-villoſe on the outſide. Seeds in the female florets obovate, remarkably acuminate at bottom, three-ſided and compreſſed, ſmooth, black, bald. The calycine leaflets are oblong, acuminate, a little longer than the flower, rugged on the outſide, within from the baſe to the middle poliſhed and whitiſh. Florets of the ray five or ten, with ovate, three-toothed petals. The large chaffs, ſeem by their ſhape, ſubſtance and ſituation to belong to the calyx[d].

Native of Virginia, cultivated about 1661, by Mr. Walker, as appears from Plukenet[e]; who ſays, that thirty years before (he publiſhed his Phytographia) he gathered a ſpecimen of this plant in a garden belonging to Mr. Walker, at Weſtminſter. Mr. Ray alſo (in 1686) ſays, that he cultivated it ſome years in his little garden at Cambridge, and that he had it from Walker, a gardener at London, whoſe ſon brought it, with other rare plants, from Virginia.] Mr. Miller had ſeeds of it from his good friend Dr. Thomas Dale, who ſent them from South Carolina: he ſays, that it grows alſo plentifully in ſeveral parts of the Spaniſh Weſt Indies. It flowers in july, but ſeldom produces good ſeeds in England.

PROPAGATION AND CULTURE.

1. The firſt may be propagated by ſowing the ſeeds on a hot-bed early in the ſpring; and when the plants come up, they ſhould be tranſplanted on another hot-bed, at about five or ſix inches diſtance, obſerving to water and ſhade them until they have taken new root; after which time they muſt have a pretty large ſhare of freſh air in warm weather, by raiſing the glaſſes of the hot-bed every day, and they muſt be duly watered every other day at leaſt. When the plants have grown ſo as to meet each other, they ſhould be carefully taken up, preſerving a ball of earth to their roots, and each planted into a ſeparate pot filled with light rich earth; and if they are plunged into a moderate hot-bed, it will greatly facilitate their taking freſh root; but where this conveniency is wanting, the plants ſhould be removed to a warm ſheltered ſituation, where they muſt be ſhaded from the ſun until they have taken new root; after which time they may be expoſed, with other hardy annual plants in a warm ſituation, where they will flower in july, and their ſeeds will ripen in ſeptember. But if the ſeaſon ſhould prove cold and wet, it will be proper to have a plant or two in ſhelter, either in the ſtove, or under tall frames, in order to have good ſeeds, if thoſe plants which are expoſed ſhould fail, whereby the ſpecies may be preſerved.

2. This may be propagated by parting the roots in autumn, and may be planted in the full ground, where it will abide the cold of our ordinary winters very well.

Spikes two, ſpikelets bifarious acuminate, culm branched knee jointed, joints ſheathed.

14. Paſpalum filiforme. *Filiform Paſpalum.*
Lin. ſpec. ed. Willd. 333. *Swartz prodr.* 22. *deſcr.* 136.
Spike ſubſolitary linear-one-ranked, ſpikelets ovate compreſſed, culm and leaves filiform.

15. Paſpalum decumbens. *Proſtrate Paſpalum.*
Lin. ſpec. ed. Willd. 333. *Swartz prodr.* 22. *deſcr.* 138.
Spike ſingle directed one way, peduncles very long, ſpikelets alternate orbiculate-acuminate ſmooth, culm procumbent.

DESCRIPTIONS, *&c.*

Theſe Graſſes are all of foreign growth, none natives of Europe, but of the Eaſt or Weſt Indies, except two, one indigenous of China, the other of Japan.

1. This is a proſtrate annual graſs with the ſheaths of the leaves almoſt ſpathaceous. Spikes few, with the rachis dilated to the width of the ſpike itſelf, which is diſtich and directed one way. Flowers orbiculate. Leaves pubeſcent on both ſides: very hairy in Thunberg's ſpecimen. Inner glume of the calyx convex even; outer flat with a raiſed line.—Native of South America, and Japan [a].

2. Culms erect, hirſute at the baſe, a foot high and more. Sheaths of the leaves purple, ciliate at the edge, and covering the joints at the baſe, hirſute. Leaves even, with a longitudinal whitiſh line above. Spikes often reflex. Calyxes roundiſh, ovate, ſmooth, blunt, gibbous; the flatter valve puſhed in at the baſe, and impreſſed with a pair of dimples in the middle [b].
Native of the Eaſt Indies. Introduced in 1778, by Sir Joſeph Banks. It flowers from july to ſeptember, and is perennial [b].

3. Culm ſmooth, three feet high. Leaves ſomewhat rugged, ſmooth, ſtriated, ſhort. Spikes three or four. Calycine glumes equal, ovate, acute, villoſe, pale with three raiſed lines. It differs from *P. diſſectum* in having a hirſute rachis; and ovate, acute, villoſe flowers: from *P. virgatum* in being leſs, and in having the flowers alternate in a double row only.—Native of Japan near Nagaſaki [c].

4. This grows ſpontaneouſly in the Caribbee iſlands, where it is called by the French *Herbe à oiſeaux*. The root is thickly fibroſe, and perennial, and throws up ſeveral annual, erect ſtems, of about four feet high, and thicker than a quill at the baſe; round, gloſſy, and in part covered by the ſheaths of the leaves. The leaves are ſeated at the joints of the ſtems, and are ſmooth on both ſides, and hiſpid in a retroverted direction on the borders. They are about two feet and a half long, with a ſheath almoſt a foot long, and about an inch wide. The ſpikes are alternate, at the top of the ſtem, very ſpreading, ſhortly footſtalked, hairy at their origin, and about four inches long; and in number uncertain, from four to twelve. The ſhaft or midrib of the ſpike is flat-membranaceous, and ſmooth, green. The flowers are obverſely ovate, very compreſſed, and marked on each ſide by a longitudinal nerve. The glumes of the calyx are villoſe at their tips on the borders. The anthers are oblong, haſtated, and incumbent, and of a dingy yellow; the ſtigmas purpliſh: the ſeeds gloſſy and brownith [d]. Outer valve of the calyx very ſhort, with the edge hirſute.—Native of Jamaica [e]. Perennial.

5. This is an annual graſs, and more erect, with the panicle as it were in whorls, with very numerous, linear, filiform, very narrow ſpikelets, all directed one way: the flowers are digeſted in a double row, and are ſharpiſh [f]. Culm a foot high. Leaves nine inches long, ſheath rough. Panicle three inches long, purple or green.
Native of Jamaica, in clayey moiſt grounds [g]. Introduced in 1782, by Monſ. Thouin. It flowers here in july and auguſt [g].

6. Root perennial, fibroſe, whitiſh. Culm flexuoſe, ſmooth, cylindric, two feet high, ſolid, rooting at the knots: branches alternate. Leaves lanceolate, ſmooth, ſlightly ſtreaked, a little waved at the edge, often three inches long, and eight lines wide. Sheath a little ſhorter than its internode, ſtipuled and ruffet at the top. Each ſheath, beſides the part of the ſtem which belongs to it, incloſes the rudiment of another ſtem. Stipule very ſhort, ciliate, whitiſh. Spike ſimple, five or ſix inches long. Common peduncle or rachis alternate, membranaceous, ciliate at the edge, ſeven or eight lines long, and a line wide, bearing on its lower ſurface as far as eighteen flowers. Pedicel flatted, ſcarcely a line in length. Calyx ruſſet: valves oblong, ciliate at the point, very much waved on the ſides, principally at the baſe; the upper convex, the lower concave. Valves of the corolla equal, oval, membranous, uncoloured, a little ſhorter than the calyx: upper convex, lower concave. Filaments attached to the baſe of the germ, and twice as long as the corolla. Anthers elongated, twin, reddiſh. Germ oval, very ſmall and ſmooth. Styles the length of the corolla. Stigmas nearly the ſame length, white and very hairy. They iſſue from the flower and bend to each ſide at the time of fecundation. Seed covered by the corolla, and of the ſame ſize and colour with it: truncate at the top of the convex ſide, and a little grooved on the flat ſide: ſubſtance horny, ſemitranſparent. It differs from this genus only in having the corolla ſhorter than the calyx, and the filaments longer than the flower.
It is a native of Peru, whence it paſſed into Spain and France. It has been cultivated with ſucceſs at Paris. The ſeeds have been in part abortive, but as it runs at the root it may be eaſily increaſed. The height and abundance of its ſtems, the ſize of its leaves, and the ſucculence of all its parts render it a proper graſs for cultivation [h]. But theſe graſſes from hot countries never are found to anſwer in England.

7. This is very like the preceding, differing only in its creeping culm, rooting at the joints, narrower leaves, and a more ſlender panicle.—Native of Surinam. Perennial [i]. By the preceding Willdenow muſt ſurely mean the *paniculatum*.

8. Culms erect, leafy, hairy above. Leaves and ſheaths hairy all over, and bearded at the mouth, flat, nerved. Spikes almoſt erect, ſubſeſſile. Rachis narrower than in *P. ſcrobiculatum*. Flowers directed one way, alternate, ſmooth, on hairy pedicels, calyxes

[a] Linn. ſpec. & ſyſt. & Thunb. jap. [b] Linn. mant. [c] Hort. kew. [d] Thunberg. [e] Jacquin. [f] Linn. ſyſt. [g] Linn. ſpec. [h] Sloane. [i] Hort. kew. [k] Linn. tranſ. [l] Willdenow.

marked with from three to five nerves.—Native of China, whence it was ſent by Bladh.

Retzius affirms, that in the *P. diſſectum*, which he received from Tranquebar, the leaves were entirely ſmooth, as well as in the cultivated graſs: which contradicts what is ſaid above from Linneus and Thunberg.

9. This, according to Willdenow, differs from *P. diſſectum* in the ſmoothneſs of the leaves and flowers. Is not then the *P. diſſectum* of Retzius the ſame with this?—Native of the Eaſt Indies; and of the Society Iſles, if this be the ſame with P. orbiculare of Forſter, as Willdenow ſuſpects.

10. Culms filiform, ſlender. Leaves ſhort, acute, ſpreading at the baſe of the culm; and thence the ſheath extending almoſt to the baſe of the culm terminate in a very ſhort leaf. Spikes linear. Flowers alternate, pedicelled, preſſed cloſe. Rachis flat, ſomewhat flexuoſe. Calyxes oval, acute, flat, green, ſtriated, naked; valves equal. One valve of the corolla of the ſame form and ſize with the calyx; the other ſmaller. It has the appearance of *Panicum diſtachyon*, and aſſociates rather with this genus than with *Milium*.

Native of Malabar, on the borders of fields; ſent by Koenig[a]. It varies ſometimes with three ſpikes together[b].

11. Culm ſimple, decumbent towards the root. Leaves lanceolate, acute, flat, ſhort. Sheaths ſtriated, hairy at the baſe. Spikes almoſt four-cornered, one ſhortly pedicelled. Rachis flat, even. Florets approximating, alternate, ſubſeſſile, ovate, acute. Glumes both of calyx and corolla equal, ovate, ſtriated. Filaments longer. Anthers very dark blue. Stigmas pencilled, blue[c].

According to Linneus it is a foot high. Leaves involute-ſubulate. Spikes upright, approximating, directed one way; with alternate, acuminate flowers, all having three ſtamens.

Native of Jamaica, and other iſlands of the Weſt Indies, in moiſt meadows. Introduced in 1776, by John Fothergill, M. D. It is a biennial graſs, and flowers in july[d].

12. Height from one to two feet. Culm ſimple, compreſſed a little, ſmooth. Leaves linear-lanceolate, a ſpan long at moſt, quite entire, ſtriated, ſmooth, rolled in at the edge, ciliate at the baſe. Sheaths compreſſed, villoſe at the neck. Spikes two, ſometimes but ſeldom three, ſeſſile, equal, from three to five inches long, linear, yelloviſh. Rachis linear, compreſſed, ſmooth. Spikelets in pairs, directed one way, ſubſeſſile. Valves of the calyx equal; outer roundiſh, convex, with whitiſh hairs thinly ſet about the edge; inner flat or concave, pale green. Valves of the corolla a little leſs than thoſe of the calyx, more tender, whitiſh. Anthers whitiſh. Styles filiform. Stigmas villoſe, whitiſh.

P. diſticbum is decumbent: the leaves of that are ſhorter and flat; the ſpikes almoſt erect, ſhorter, ſomewhat quadrangular; the florets larger, oblong, acute; the gemitals blue, and the colour of the whole bright green.

P. conjugatum is common in the Weſt Indies in moiſtiſh meadows. The Engliſh there call it *Sourgraſs*, and cattle do not eat it.

13. This is a foot high. Roots numerous, filiform. Culm creeping, ſheathed at the joints. Sheaths diſtich, compreſſed, wide, ſtriated, ſmooth. Leaves lanceolate-linear, acute, ſpreading, hairy at the neck of the ſheath. Spikes ſpreading, an inch long, pedicelled. Rachis linear, ſubflexuoſe. Spikelets ovate, plano-convex, on very ſhort pedicels. Calycine glumes equal, ovate, acute, ſmooth. Corolla ſcarcely ſmaller. Anthers and ſtigmas purple. It is known by its branching culm, by its ſheaths and ſpikelets.

Native of Jamaica, in paſtures where the ſoil is clay.

14. This is a tufted graſs, two feet high. Culm upright, ſimple, ſomewhat compreſſed, ſheathed, ſtriated. Joints blackiſh. Leaves equalling the culm, half round, ſomewhat three-ſided, acute, ſtriated, ſmooth. Sheaths ſomewhat hairy at the neck of the leaves. Spike upright, ſcarcely wider than the culm, compreſſed, ſmooth, from two to three inches in length. Rachis linear, convex not flat, a little flexuoſe. Spikelets pedicelled, approximating, ſmooth, a little convex on the inner ſide. Calycine glumes ovate, ſmooth. Corolline of the ſame length and form with the outer ones. Anthers yellow. Stigmas pencilled, blueiſh.—In a more fertile ſoil, ſometimes it has three or four ſpikes, but the culm and leaves are always filiform, by which it is diſtinguiſhed from *P. diſſectum*, which is proſtrate and not ſcſpitoſe, the leaves linear, the florets oval and pubeſcent, and it grows in a dry calcareous ſoil.

P. filiforme is common in the Weſt Indies, in open hard fields.

15. This is a procumbent graſs ſcarcely a foot in length. Culm branched, divaricating, round, ſmooth. Leaves widiſh, lanceolate, pubeſcent on both ſides, with the edge ſubciliate. Sheaths the length of the leaves, even, villoſe at the neck. Peduncles from the ſheaths ſolitary, from four to ſix inches long, looſe, one-ſpiked. Spikes nodding, an inch long. Spikelets directed one way, on ſhort pedicels. Rachis membranaceous, linear, flat. Calycine glumes ovate, ſmooth. Corolline very like them. Anthers pale. Stigmas long, pencilled. This differs from its congeners, in its divaricating diffuſed culm, and ſolitary, axillary ſpike, on a long pedicel.

Native of Jamaica, on the weſtern ſide of the iſland, on the mountains, in a dry ſandy ſoil[e].

PASQUE-FLOWER. See *Anemone*.]

PASSERINA. (*So named from the form of the ſeed, like a bird's tongue.*)

Lin. gen. n. 489. *Reich. n.* 530. *Schreb. n.* 668. *Juſſ.* 77.

Claſſ. 8. 1. Octandria Monogynia.

Nat. order of *Vepretulæ*, *Thymelææ*, Juſſ.

GENERIC CHARACTER.

CAL. none.

COR. one-petalled, ſhrivelling. *Tube* cylindrical, ſlender, ventricoſe below the middle. *Border* four-cleft, ſpreading: *ſegments* concave, ovate, blunt.

STAM. *Filaments* eight, briſtle-ſhaped, the length of the border, placed upon the point of the tube. *Anthers* ſubovate, erect.

PIST. *Germ* ovate, within the tube of the corolla. *Style* filiform, ſpringing from the ſide of the very point of the germ, the ſame length with the tube of the corolla. *Stigma* capitate, hiſpid all over with villoſe hairs.

PER. coriaceous, ovate, one-celled.

SEED ſingle, ovate, acuminate at both ends, with the points oblique.

OBS. P. capitata *has flowers without a tube, and ſixteen ſtamens, the eight inner ones caſtrated.* P. uniflora *has eight ſtamens, beſides the rudiments of eight anthers at the bottom of the flower.*

ESSENTIAL CHARACTER.

Cal. none. *Cor.* four-cleft. *Stam.* placed on the tube. *Seed* one, corticate.

Thunb. prodr. cap. 75.
Leaves ovate hirsute, flowers in heads, branches rigid.
19. Passerina pentandra.
Thunb. prodr. cap. 76.
Leaves ovate hirsute, spike ovate terminating.]

DESCRIPTIONS, *&c.*

1. This rises with a shrubby stalk five or six feet high, sending out branches the whole length, which, when young, grow erect, but as they advance in length, they incline towards a horizontal position; but more so, when the small shoots at the end are full of flowers and seed-vessels. The branches are covered with a white down like meal, and are closely beset with very narrow leaves in four rows, so that the young branches seem as if they were four-cornered. The flowers come out at the extremity of the young branches, from between the leaves on every side, they are small and white, so that they make no great appearance. The seed-vessels are small, and seem withered and dry. [The tube of the corolla is the length of the germ. The floral leaves have a wide membranaceous rim at the base, which is not the case in the rest [f].]

It is a native of the Cape of Good Hope, whence it was first brought to the gardens in Holland. [Mr. Miller cultivated it here in 1752. It flowers from june to august [g].]

2. This has shrubby stalks, which rise to a greater height than the former; the branches grow more diffused, and are covered with a mealy down. Leaves imbricate, short, thick, succulent, smooth and green on the outside, but downy on the inner. Flowers small and white, like those of the former, and appearing about the same time.

Native of Spain and Portugal, [Provence, Italy and the Levant [h]. Reichard remarks, that Gouan (*illustr.* 27. *t.* 17. *f.* 1.) refers Sanamunda 3. of Clusius to his Daphne dioica.

3. This has so entirely the appearance of an *Erica*, that at first sight no one would doubt of its being one. It has the stature of the first species. The branchlets are pubescent. The leaves short, (like those of *Erica*) ovate-oblong, fleshy, opposite, the floriferous one subcordate. Flowers sessile, on the uppermost branchlets, lateral. Seeds ovate, black, shining. Tube of the corolla globular, inflated, (like that of *Erica*) coloured, as the border.—Native of the Cape of Good Hope [i].

4. Leaves scattered. Heads terminating, globular. Peduncles tomentose, thickened. Flowers many, white, sessile without a tube. Stamens above the throat sixteen, the eight inner of which are castrated [k]. Stems shrubby, compound, with rod-like red branches. Leaves erect, acuminate. Common peduncles from the end of the branches, turbinate, tomentose [l].—Native of the Cape of Good Hope.]

5. This has a shrubby stalk, rising five or six feet high, sending out many branches which are naked to their ends, where they have oblong leaves, standing erect, and having hairy points. The flowers are small, white, and come out among the leaves at the end of the branches. [Linnæus remarks, that the flowers are purple, with the throat villose.

Native of the Cape of Good Hope, Spain and the Levant.] It flowers here in june, but no seeds are produced.

6. This has a shrubby stalk, seldom rising more than a foot high, dividing into many branches, which are slender, smooth, and spread out on every side. Leaves dark-green, having the appearance of those of the Fir-tree, but narrower. The flowers are larger than those of the former, and the upper part of the petals is spread open flat; they are of a purple colour, and appear about the same time as the former.

[There are eight stamens at the throat of the corolla, and eight rudiments of anthers lie concealed at the bottom [m].—Native of the Cape of Good Hope.

7. Flowers on the outside very hirsute, white; within, in the living plant yellow, in the dry plant black.

8. The flowering branches resemble a leafy spike.

9. This resembles *P. ericoides*, but differs by having the flowers in heads.—These were found at the Cape of Good Hope by Thunberg.

10. Branches one-flowered. Leaves opposite, subimbricate, blunt with a point, on the outside wrinkled as it were with the veins raised, within concave, very smooth. Stamens eight, above the tube. Stigma capitate, without the tube. It is easily distinguished by the large borders of the flowers, silky on the outside.

[f] Linn. syst. [g] Hort. kew. [h] Linn. spec. [i] Linn. mant. and syst. [k] Linn. syst. [l] Linn. amoen. [m] Linn. syst.

Native of Africa. Recently introduced, says Mr. Curtis, from the Cape. It flowered in 1794, at Meſſ. Lee and Kennedy's, and forms a ſmall neat ſhrub, like *Phylica ericoides*.

11. The leaves are more rigid, and very like thoſe of Gnidia.—Native of New Zealand, in the fiſſures of rocks, by the ſea coaſt, and at the tops of mountains.

12. Native of New Zealand.

13. Native of New Zealand, on dry mountains.

Theſe diandrous Paſſerinas have the ſmell of Syringa flowers, and are evergreen. They are not ſeparated from their natural genus, though the number of ſtamens be leſs. The *Struthiola* might have been referred to this genus, had it not been for the nectaries. *Daphne* alſo agrees with *Paſſerina**.

14 to 19. Natives of the Cape of Good Hope, where they were found by Thunberg.]

PROPAGATION AND CULTURE.

Theſe ſhrubs from the Cape of Good Hope may be increaſed by cuttings during the ſummer months, planted in a bed of loamy earth, and cloſely covered with a bell or hand-glaſs to exclude the air, ſhading them from the ſun, and refreſhing them now and then with water. They will take root in about two months, when they may be planted each in a ſmall pot filled with loamy earth; placing them in the ſhade till they have taken new root: then remove them into a ſheltered ſituation, there to remain till October, when they muſt be placed in the green-houſe, and treated as Myrtles.

Thoſe alſo which produce ſeeds, or when they can be procured, may alſo be propagated that way. Sow them in autumn, ſoon after they are ripe, in ſmall pots filled with light earth, plunged into an old bark-bed, under a common frame in winter. The plants will come up in the ſpring, and may be treated like the cuttings: but the ſeedling plants will grow more erect, and make a handſomer appearance.

2. The ſecond ſort will live abroad in common winters, in a dry ſoil and warm ſituation; but in hard froſts, the plants are frequently deſtroyed; one or two therefore ſhould be kept in pots, and ſheltered in winter.

PASSERINA. See *Gnidia*, *Lachnæa*, *Linum*, *Stellera*, and *Struthiola*.]

PASSIFLORA. (*Altered by Linnæus, from the old name* Flos Paſſionis, *which was given it at the firſt diſcovery by the Europeans, from a fancy that they ſaw all the inſtruments of our Saviour's paſſion in the flower.*)

Leaves pedate serrate.

DESCRIPTION, *&c.*

This beautiful genus is compoſed of climbing herbaceous plants, ſometimes woody, eſpecially at bottom. Leaves alternate, ſtipulaceous, ſimple; in a few undivided; in a few others multifid or palmate; but in the greater part lobed: lobes in ſome two, but in more three. In *P. heterophylla*[a], the lower leaves are undivided, and the upper ones pedate. The petiole in ſome ſpecies is naked, in others glandular on each ſide. The tendrils or claſpers by which the ſlender weak ſtems ſuſtain themſelves are axillary. The peduncles are alſo axillary, from one to three together, each ſuſtaining a ſingle flower, (except in *P. holoſericea*, in which they are many-flowered;) below the calyx they are commonly jointed; and have an involucre at the joint, which is frequently three-leaved or three-parted; the diviſions entire, or ſometimes, but rarely, cut or jagged; ſometimes however this involucre is very ſmall, or conſiſts only of one leaf, or is entirely wanting.—This genus, according to Juſſieu, is allied to the *Cucurbitaceæ* in habit, number of parts, lateral receptacles of the ſeed, and petaloid calyx: for he conſiders *Paſſiflora* as having no corolla, but a calyx divided into ten parts; five of which are exterior, and conſtitute the calyx of Tournefort and Linneus; the other five interior and petaloid, the petals of thoſe celebrated authors. This genus however differs from the plants of that natural order in the ſtipules of the leaves, the ſituation of the ſtamens and germs, the crown, the periſperm, and eſpecially in having hermaphrodite, not monoecous or androgynous flowers.

The crown, which Linneus calls the *nectarium*, conſtitutes great part of the beauty of the flower in many of the ſpecies. It theſe it conſiſts of an inner crown, ſpringing from the baſe of the petals or inner calycine ſegments and beneath them, coloured, many-parted, conſiſting of numerous filiform ſegments, radiating or erect: within this is another double crown, of the ſame ſhape, but ſhorter and more flatted, inſerted into the pitcher; the inmoſt frequently converges round the central column[b].

Mr. Sowerby, who has beſtowed much attention on this genus remarks, that the larger ſpecies, as far as he has ſeen, have conſtantly two rows of principal radiated nectaries; the ſmaller commonly but one, and but half the number of diviſions in the corolla, namely, only five, whereas the others have from ten to twelve: that the repoſitory for honey alſo differs much in different ſpecies, and is a part very diſtinct from the crown, which perhaps may ſerve as a conductor, or help to ſcreen or ſecure the nectareous juice: and laſtly, that there is another ſort, which ſerves as an *operculum* under various forms, ſometimes plaited, or plaited and fringed, beſides a kind of imperfect rays, in different ſituations and ſhapes[c].

The fruit is a fleſhy berry, differing in ſhape and ſize, but moſt frequently an oblong ſpheroid, ſometimes covered with a ſolid rind, ſmooth on the outſide (except in *P. rotundifolia*, which is hairy), one-celled, containing numerous, compreſſed ſeeds, covered with a membranaceous pulpy aril: the corcle or embryo is flat, ſurrounded by a thin fleſhy periſperm or albumen[d].

Gærtner remarks, that the ſurface of the albumen being *ſcrobiculate* or full of little pits or holes, the ſeed in this genus may readily be diſtinguiſhed by this mark; which occurs only in *Guajacum*, one ſpecies of *Ucaria*, and a few others beſides.

Juſſieu ſeparates *P. Murucuia* from this genus, as Tournefort had done, under the name of *Murucuia*; on account of the difference in the crown.

Linneus placed this genus in the claſs Gynandria, on account of the ſituation of the ſtamens at the baſe of the germ. Swartz removed it to Monadelphia, becauſe they are united at bottom. Schreber and Thunberg have ſunk it in the ocean of Pentandria.

[a] Plum. ſpec. 7. mſs. 2. t. 21. *Juſſ. gen.* [b] Juſſ. gen.
[c] Linn. tranſ. 2. 19. [d] Juſſ. gen.

1. This is a perennial ſhrubby ſpecies; the ſtems are round; the younger ones very ſlightly villoſe, and climbing very high: the ſtipules are linear and acuminate: the footſtalks of the leaves are furniſhed with two pair of glandules: the leaves are ovate, ſmooth, and ſlightly ſerrated round their whole outline: the peduncles are one-flowered and ſolitary: the calyx is outwardly green, inwardly whitiſh: the petals pale purple: the filaments of the nectary are deep purple at their baſe, from thence blueiſh, and at length pale: the anthers are yellow: the ſtigmas greeniſh. The flowers have an extremely agreeable odour[a].

Mr. Miller has wholly omitted this ſpecies in his deſcriptions, though he has inſerted it in his liſt of ſpecies.

Native of the Weſt Indies. Introduced in 1731, by William Houſtoun, M.D. It flowers from may to october[b].

2. Stem perennial, long, round, branching, climbing by ſolitary tendrils. Leaves ſmooth, oppoſite. Flowers pale, large, axillary, two together. Corolla five-petalled, flat, with a crown. Berry egg-ſhaped, ſmall[c].

Linneus obſerves, in the Amoenitates Academicæ, that the figure by Piſo and Marcgrave approaches to this ſpecies, and is cited as ſuch by Plumier; but that the deſcription which Ray has copied from Marcgrave differs from this in having cordate leaves, a large ſerrated involucrum, and ten petals: and that therefore the figure of Marcgrave relates to this ſpecies, but the deſcription to another.

Native of Braſil, the iſland of Dominica, and Cochinchina.]

3. This has ſlender three-cornered ſtalks, which ſend out tendrils at each joint, faſtening themſelves to any neighbouring ſupport by them, and climbing to the height of twelve or fourteen feet. Leaves about two inches long, and one inch wide, of a light green colour; on ſlender petioles, an inch in length, from which ariſe three longitudinal veins, one running through the middle of the leaf, the other two diverging to the ſides, but drawing towards each other again at the point. Flowers axillary, on ſlender peduncles, an inch long. Calyx compoſed of five oblong, narrow, purpliſh leaves; within which are five narrower petals of the ſame colour, turning back after they have been ſome time expanded. The column in the middle of the flower is very long and ſlender, ſupporting a round germ, from the baſe of which ſpread out five ſlender ſtamens. Fruit oval, about the ſize of a ſparrow's egg, changing to a purple colour when ripe; and filled with oblong ſeeds incloſed in a ſoft pulp.

[Linneus remarks, that the leaves are ovate, but the older ones ſubcordate; that the young ones are ſcarce apparently ſerrate; and that the glands on the petioles are hardly viſible.

According to Dillenius, the ſtem attained the height of three cubits in three years from the ſeed, with few branches. Leaves cloſe, rigid, ſmooth, deep green above, ſomewhat paler underneath. Petals of an obſolete purple colour, or ſuch as is ſeen on poliſhed copper, whence the trivial name. Crown very ſmall; rays ſhort, rigid, ſmooth, ſaffron-coloured, very dark violet and ſhining at the baſe, not ſpreading out but converging, and in the centre a cavity full of clear honey juice. Styles purple, green at the end. Filaments alſo purple. The flowers open in the evening, and laſt a day or two; but have no ſmell[d].]

It grows naturally in the Bahama iſlands, whence Mr. Cateſby ſent the ſeeds to England. [Cultivated by Mr. Miller about 1731.

4. With a perennial root, and a climbing ſtem of about a finger's thickneſs: the leaves cordate, acute, footſtalked, reticulated towards the baſe: the footſtalks deſtitute of glands: the flowers red: the nectaries red with a white ring: the involucres quite entire: the fruit globoſe, and variegated with red and yellow, and having a ſweet pulp.

[a] Jacquin. [b] Hort. kew. [c] Loureiro.
[d] Hort. elth.

Native

Native of South America, about Lima; found there by Feuillée [1].]

5. Stem thick, triangular, by ſlender tendrils thrown out at every joint riſing to the height of fifteen or twenty feet. At each joint is one leaf, ſix inches long, and four broad in the middle, of a lively green and thin texture, having a ſtrong midrib, whence ariſe ſeveral ſmall nerves, diverging to the ſides, and curving up towards the top. Petioles pretty long, having two ſmall glands in the middle. Two large ſtipules encompaſs the petioles, peduncles and tendrils at the baſe. Peduncles pretty long, having alſo two ſmall glands in the middle. The cover of the flower is compoſed of three ſoft velvety leaves, of a pale red, with ſome ſtripes of a lively red colour; the petals are white, and the rays are blue. The flowers being large make a fine appearance, but they are of ſhort duration; there is however a ſucceſſion on them for ſome time. Fruit roundiſh, the ſize of a large apple, yellow when ripe, having a thicker rind than any of the other ſorts; incloſing a ſweetiſh pulp, in which are lodged many oblong black ſeeds, of a browniſh colour, a little rough to the touch. It grows naturally in the Weſt Indies, where the inhabitants call it Granadilla. The fruit is ſerved up there in deſerts.

[Linneus ſays it is a native of Dominica and Tortuga. In the Kew catalogue it is ſaid to be a native of Dominica; and to have been cultivated by Mr. Miller in 1731.

6. Stem almoſt ſimple, thick, membranaceous at the four corners, ſomewhat hiſpid. Leaves petioled, five or ſix inches long, entire, ſomewhat rugged, but without any pubeſcence. Tendrils very long, axillary. Stipules in pairs, ovate, at the baſe of the petioles; on which there are ſix glands. Peduncles oppoſite to the petioles, thicker. Flowers very large, encompaſſed by a three-leaved involucre, the leaves of which are roundiſh, concave, entire, ſmooth, pale. Calyx five-leaved: the leaflets broad-lanceolate, membranaceous at the edge, thick in the middle, ſomewhat ſpongy, very white within. Petals of the ſame ſhape, but thinner, blunter, red within, white on the outſide. Crown five-fold: outer rays in a double row, longer than the petals, filiform, round, white and violet variegated; two inner alſo in a double row, very ſhort, erect; inmoſt flat near the column of the germ. Column ſtraight, cylindrical, variegated. Germ white. Styles purple. Stigmas black, bifid within. Fruit very large, oblong, fleſhy; the pulp purple [2].]

Mr. Miller ſays it has much the appearance of the preceding both in ſtalk and leaves; but the ſtalk has four angles, the leaves alſo of that are not hollowed at the baſe: the flower is much larger, though very like the other in colour; the fruit is near twice as large, and of a very agreeable flavour.

Jacquin remarks that the flowers are very ſweet as well as beautiful, reſembling in colour and ſtructure thoſe of *P. laurifolia*, but a little larger; that the fruit is ſhaped like an egg, ſhining, greeniſh yellow, larger than a gooſe's egg, ſmelling ſweet, having a ſoft ſpongy rind, a finger in thickneſs, brittle, whitiſh, inſipid: the pulp ſucculent, of a wateriſh colour, and ſweetiſh ſmell, and very pleaſant taſte, ſweet and gently acid, contained in a membrane or bag, which may be eaſily ſeparated from the rind.

Mr. Sowerby diſtinguiſhes this from the next ſpecies, with which it has been confounded. They are very much alike, as to general appearance, before they flower, excepting that the leaves in this have generally twice as many ſide veins. The flowering, even at a diſtance, will diſtinguiſh them pretty eaſily, the *quadrangularis* being rather compreſſed and never oblong, as that of the *alata* always is; the former being alſo deſtitute of awns. The glands on the petioles are ſaid to be ſix in this, but it is not conſtantly ſo; and there are ſometimes ſix in the *alata*. The peduncle affords a moſt certain diſtinction. The colour of the plant will not diſtinguiſh them.—He then proceeds to deſcribe the flower thus: Pedunele triangular. Involucre of three large concave oval leaves, ſerrate towards the baſe. Pedicel cylindrical, rather more ſlender at the inſertion into the concave baſe of the flower. Petals ten or twelve, the outer five or ſix thick and ſomewhat ſpongy, a little concave, broad, ending obtuſely and without awns, the inner five or ſix thinner and ſmaller. Principal rays (of the crown) in two rows cloſe to each other, alike, awl-ſhaped and ſtanding perpendicularly, or nearly at right angles with the petals, which they exceed in length. Imperfect rays, four or five rows of irregularly-ſituated protuberances, nearly conical, very ſmall, on an inclined plane. Imperfect operculum, or cover to the antinectary, horizontal, partly divided into rays, which by their tips reſt on a thickened part of the column ſupporting the fructification. This ſeems to be one part more than in any other Paſſiflora. Operculum or cover to the nectary horizontal, and flatiſh at the end, which is edged with two rows of little imperfect or irregular teeth, reſting on the column. Nectary round the concave baſe of the corolla, with a protuberant half partition on the ſide fartheſt from the column [3].

What are here called the petals, Juſſieu regards as the calyx. Linneus takes the middle way, naming the outer leaflets the calyx, and the inner more tender ones the corolla. Mr. Sowerby conſiders the involucre as the perianth. It ſuffices to mention the difference of opinion in a matter of too little conſequence to excite a controverſy. I only remark, that in doubtful caſes of little moment, it is far better to leave things as we find them, than to make changes which only ſerve to breed confuſion.

Native of Jamaica and other iſlands of the Weſt Indies, in woods [4]. Jacquin ſays he did not find it wild any where, but in gardens every where; to the ornament of which it contributes very much, by forming large and very cloſe arbours in a few months. It is attended however with this inconvenience, that theſe arbours ſerve to ſhelter venomous ſerpents, which lurk there to ſeize on little animals that come for the fruit, of which they are very fond.

The fruit is brought to table whole, and is much eſteemed; and the pulp taken out of the rind, with or without the ſeeds, firſt put into wine. The French call it *Granadille*; and Browne, the *Granadilla Vine*.

Jacquin has a variety, which he names *Paſſiflora fulcata*. It perfectly reſembles the *quadrangularis*, except in the ſize and form of the fruit, which is roundiſh, frequently larger than a child's head, and marked with a circular tranſverſe groove, deep enough to lay a finger in. It grows on Terra firma.

P. quadrangularis was cultivated by Mr. Miller in 1768, and flowers in our ſtoves in auguſt and ſeptember [5].

7. This is very like the preceding at firſt ſight; the open flower has alſo a general reſemblance: but the peduncle is cylindrical; the three diviſions of the involucre ſmall, lanceolate, with glandular ſerratures; the pedicel thickeſt at the inſertion into the convex baſe of the flower; the five or ſix outer petals oblong with an awn, the inner longer; the outer principal rays thinneſt and ſhorteſt; imperfect rays in a double row, below and diſtinct from them a ſingle row: no imperfect operculum; operculum partly horizontal and partly turning up to the column, then folding back down again and embracing the column, with which it is ſo connected that it appears inſeparable, but it is not joined to the column; nectary round the column, confined by the baſe of the flower—the column comes to the bottom of it, which is not the caſe in the *quadrangularis* [6].

If this ſpecies does not equal the *coerulea* in elegance, it exceeds it in magnificence, in brilliancy of colour, and in fragrance, the flowers being highly odoriferous [7].—It is a native of the Weſt Indies, and according to the Kew catalogue, was introduced in 1772, by Mr. William Malcolm. Mr. Curtis informs us, the nurſerymen report, that it was firſt raiſed

[1] Linn. amoen. [2] Swartz. [3] Linn. tranſ. [4] Swartz. [5] Hort. kew. [6] Sowerby in Linn. tranſ. [7] Curtis.

in this country, by a gentleman in Hertfordshire, from West Indian seeds.

8. Stem suffrutescent, with very divaricating, filiform branches. Leaves a little emarginate at the base, nerved and very smooth, on short petioles compressed a little, having two glands under the base of the leaf. Tendrils very long. Peduncles the length of the petioles. The three leaflets of the involucre are roundish, concave, with blunt glandular toothlets about the edge, and pale. The five leaflets of the calyx are broad-lanceolate, slightly membranaceous at the edge, horned with a point or awn, smooth, variegated on the inside with blood-red dots. Petals five, the length of the calyx, narrower, acuminate, with blood-red dots scattered over them. Crown triple; the outer rays half the length of the petals, the middle longer than the petals with toothed points, the inner shorter near the column, all variegated with red and violet. Column cylindrical, straight. Filaments variegated. Germ yellow. Styles variegated. Stigmas bifid, black above. Fruit ovate, watery [f].

Jacquin describes it as a woody plant, smooth all over; the younger branches round and green. Leaves some acute, others obtuse, shining, flat. Peduncles solitary. Flowers very handsome and odoriferous. Involucre close to the calyx; leaflets ovate, acute, greenish, either quite entire or having a few teeth. Calycine leaflets pale green on the outside, variegated pale and flesh-colour within. Petals rose-coloured within, pale without. Crown elegantly variegated transversely with white, purple and violet. Fruit three inches long, with a coriaceous, yellow, soft, tough rind, containing a watery, sweet, tasteful juice, having a peculiar fine smell. In the West Indies they suck this pleasant juice through a hole in the fruit. The French call it *Pommes de Liane*, and the English *Honeysuckle*. Browne says it is cultivated in many parts of America for the sake of its fruit, which is very delicate, and much esteemed by most palates; it is about the size of a hen's egg, and full of a very agreeable gelatinous pulp. He calls his fourth species *Water Lemon*, and informs us that it is a native of Jamaica, frequent in the woods, and supplying the wild hogs with a great part of their food in the season. Jacquin says it grows every where in the island of Martinico; Merian in Surinam; it is pretty general in the West Indies. Mr. Bentick introduced it here in 1690. It flowers in june and july [g].

Mr. Sowerby gives the following particulars to distinguish this species. Peduncle, the lower part cylindrical, becoming triangular at the insertion of the involucre, which consists of three large concave obovate leaves, serrate towards their extremities with large glands, ending in two or three simple serratures; pedicel almost conical, narrowing into the deep base of the flower; the six outer petals lanceolate with an awn, the inner smaller; principal rays in two sets, the outer shortest, spreading diagonally, base cylindrical, apex abrupt and irregular, flattish, the inner nearly upright, some a little clavated, others bluntly awl-shaped; imperfect rays in two or three rows irregularly situated; operculum a horizontal plane, touching the base of the column, which confines it by spreading a little over the edge; nectary below the base of the column, round the concave base of the flower.]

9. This has slender stalks, sending out many small branches, and climbing to the height of twenty-five or thirty feet; by age they become woody towards the bottom, and their joints are not far asunder. Leaves on short slender petioles, three inches and a half long, and two broad in the middle, rounded at the base, but terminating in a point at top, smooth, entire, and of a lively green colour. Flowers axillary, on long peduncles. Calycine leaves oblong, green on the outside, but whitish within. Petals oblong, white. Rays blueish purple, inclining to red at bottom. Column short and thick. Germ oval, swelling to the size of a pullet's egg, and changing to a pale yellow when ripe. The flowers have an agreeable odour, but seldom continue twenty hours open: there is a succession of them from june to september, and sometimes the fruit will ripen here.

It grows naturally at La Vera Cruz in New Spain, where it was found by Dr. Houstoun, who sent the seeds to England in 1731. [It had been before found by Plumier in the island of Dominica.

10. Native of Jamaica [h].

11. Stem angular, lanuginose all over. Tendrils simple, smooth. Leaves petioled, rolled back at the edge, sometimes toothletted, veined, smooth above, lanuginose underneath. Stipules in pairs, linear-lanceolate, toothed, sharp. Flowers solitary, peduncled, pendulous, purple. Peduncles round, smooth. Calyx (Involucre) three-leaved, smooth, deciduous, much shorter than the tube. Corolla tubular, as in *Gardenia Thunbergia*, permanent: tube the length of the finger, slightly angular, smooth; border ten-cleft, with the segments ovate, concave, mucronate below the tip, the five outer (calyx) thicker, the five inner (corolla) thinner and more coloured. Nectary (crown) in the throat, very short. Column the length of the tube. Berry ovate, spotted.

Native of New Granada; where it was found by Mutis [i].

12. Stem herbaceous, climbing and twining, three-cornered, subdivided, striated, pubescent. Leaves cordate, ovate, entire, besides the two lobes having a third between them extremely obscure, a very small bristle; they are nerved, smooth on both sides, glaucous underneath and pubescent: the younger ones very thin: at the base the leaves are lobate-cordate, embracing, with the lobes lying over each other, so that the stem is as it were perfoliate: lateral lobes emarginate, with a very short bristle. Petioles very short, curved inwards, round, without glands. Stipules awl-shaped, bent down, at the base of the petiole. Tendrils supraaxillary, very long. Peduncles axillary, solitary, shorter than the leaves. Flowers middle-sized, scarlet. Calyx bell-shaped, growing to the corolla: segments erect, linear, of the same colour with the corolla. Petals between the segments of the calyx, and double their length; lanceolate, from erect spreading. Nectary single, many-parted: segments erect, linear, fleshy, green, with blunt scarlet tips. Column long. Germ ovate. Berry roundish.

Native of Jamaica, in dry hedges near the coast, on the southern side of the island; flowering in the middle of summer [k].

Reichard supposes that this may be the *P. Maracuia* of Miller, *n.* 14.

13. Stem herbaceous, twining round, grooved, hirsute, red. Lobes of the leaves entire, nerved, somewhat hispid, soft. Petioles round, red, villose, without glands. Tendrils subaxillary. Flowers alternate, nodding, on solitary one-flowered peduncles. Calyx ovate at the base: leaflets membranaceous at the edge, white within, green without, villose. Petals whitish or pale flesh-colour. Crown triple: outer rays the length of the petals, multifid, pale red; middle one-leafed, very short, plaited: inner a fleshy white rim. Germ small, villose, green. Fruit spherical, marked with six lines, scarlet when ripe, hirsute; pulp whitish. Seeds black, tuberculed, shining, covered with a pulpy aril [l].

Native of the West Indies. Cultivated in 1748, by Mr. Miller [m]. It flowers in april and may [n].]

14. This has slender angular stalks, which rise twenty feet high, sending out many branches. The flowers and tendrils come out from the same joints. The former are of a pale colour and small. Fruit egg-shaped, ovate, purple, the size of small grapes.

[The lobes of the leaves divaricate at a right angle; and the petioles are without glands [o].

The berry is spherical, herbaceous-fleshy, marked with six streaks, hirsute, pale, hollow. Receptacles linear. Seeds numerous, but only three or four ripening, ovate, pointed at both ends, turgidly lenticular, transversely wrinkled, shining, having an umbilical cord growing close to it on one side, ferruginous. Aril

[f] Swartz. [g] Hort. kew. [h] Swartz. [i] Idem.
[k] Granadilla 10. edit. 5. [l] Hort. kew. [m] Linn. syst.

membranaceous, pedicelled, white, at the top pervious and toothletted. Outer cover cruftaceous, brittle. Albumen fleſhy, hard, ſnow-white [p].

Native of South America.] Mr. Miller ſays it was found by Dr. Houſtoun, growing naturally at La Vera Cruz.

[The root is much extolled by Hernandes, as a counterpoiſon and diuretic, for eaſing pain and creating appetite.

15. Stem herbaceous, grooved, ſmooth. Leaves ovate or oblong, two-horned, with an intermediate briſtle, three-nerved, veined, ſmooth, entire: dots on the back hollowed, pellucid. Petioles grooved, ſmooth, deſtitute of glands. Tendrils ſubaxillary, filiform, long. Flowers in pairs, axillary, ſcarlet, large. Peduncles longer than the petioles, having two very ſmall, filiform ſtipules in the middle. Petals almoſt upright, blunt, a little ſmaller than the calyx. Nectary one-leafed, tubular, growing to the petals and calyx, with a yellow crown at the throat. Column longer than the corolla, erect. Berry ovate, the ſize of a pigeon's egg, pedicelled [q].

According to Browne, it is of an oblong oval form, about the ſize of a large Olive, and fleſh-coloured when ripe. Both the ſyrup and decoction of the plant is much uſed in the leeward parts of Jamaica, where it is frequent; and it is ſaid to anſwer effectually all the purpoſes for which ſyrup of Poppies and liquid Laudanum are generally adminiſtered. The flowers are moſt in uſe: they are commonly infuſed in, or pounded, and mixed immediately with wine or ſpirits; and the compoſition generally thought a very effectual and eaſy narcotic. Browne names it *Bull-hoof* or *Dutchman's Laudanum*, which are probably the vulgar names of the country.

Native of the Weſt Indies.]

16. This has ſlender, ſtriated [roundiſh ſtalks, leſs than a ſtraw, and of the ſame thickneſs from top to bottom,] of a browniſh red colour, dividing into many ſlender branches. Leaves ſhaped like the wings of a bat when extended, about ſeven inches in length or rather breadth, from the baſe to the top not more than two inches and a half, [the upper ones ſmaller, the middle wider, and the lower narrower, ſmooth and ſomewhat ſhining, the colour in the upper ones pale, in the middle deeper, in the lower darker green, with two purple tubercles or glands towards the baſe, where they are connected with the petiole;] which is ſet half an inch from the baſe of the leaf, three nerves ſpringing from it, two extending each way to the narrow points of the leaf, the other riſing upright to the top, where is the greateſt length of the leaf. [Flowers on ſhort round peduncles from the axils of the middle and upper leaves, white and of a middle ſize,] about three inches in diameter when expanded: [calyx greeniſh on the outſide, whitiſh within: petals ſomewhat ſmaller, white: rays very long and white, twiſted in the middle; at the baſe of theſe others more ſlender, like hairs; next to them a ring of white plaited ſcales collected into a ſhort tube, from the middle of which ariſes the ſhort purple column, ſupporting the germ, which is green and of an oblong ſpheroidal form. The flowers are without ſcent, open in the evening or during the night, in the month of July, and finally cloſe about eight or nine o'clock in the morning.

Dr. Sherard received it from the Amſterdam garden, without any notice of its native place of growth [r]. It is however a native of the Weſt Indies.] Mr. Miller, who cultivated it about the ſame time, ſays that it was diſcovered by Mr. Robert Millar, growing naturally near Carthagena in New Spain.

17. [Stems ſeveral, above thirty feet high in a cultivated ſtate, roundiſh and woody at the baſe: in the upper part acutely angular, ſtriated, almoſt herbaceous, nearly ſmooth, alternately branched. Lobes of the leaves very remote, elongated, entire, obtuſe, terminated by a ſmall briſtle, ſimilar to one placed between them in the middle of the leaf, each marked by a ſeries of nectariferous dots between the larger veins; leaves veined, bright green and ſmooth above, underneath a little glaucous, permanent; on ſhort, roundiſh petioles, ſlightly downy, without glands. Stipules ſmall, ſemilanceolate, acute, entire, ſmooth. Tendrils axillary, ſimple, very long, ſmooth. Flowers axillary, two together, drooping, opening early in the day, and ſmelling like honey. Peduncles twice as long as the petioles, round, ſwelling at the top, ſlightly downy, each bearing a ſingle flower. Bractes three, ſmall, ſetaceous, below the joint, at a little diſtance from each other. Corolla flattiſh at the baſe, deeply divided into ten ſegments, whitiſh and ſmooth; ſegments oblong, ovate, obtuſe; the five outermoſt (calyx) thickeſt, externally green; the innermoſt (petals) narrower and ſhorter. External crown of the nectary conſiſting of about thirty yellow rays, a little ſhorter than the corolla: middle, of greeniſh capillary rays, much ſhorter: innermoſt, a ſingle, green, plaited, truncated membrane, cloſely covering the cell where the honey juice is lodged. Genitals as long as the corolla, ſmooth. Column cylindrical, thickiſh, white. Germ oval, ſlightly triangular [s].

Mr. Sowerby remarks that the flower is much ſmaller than in *quadrangularis*, *alata*, *laurifolia*, and *cærulea*; and is remarkably different in having but one row of principal rays, and that of a quadrangular form; with the operculum or cover of the nectary curiouſly plaited: but this is a common caſe with the ſtill ſmaller ones [t].

The deſcription of *P. punctata* in Linn. ſyſt. veg. belongs to this plant, as well as his obſervation in his Mantiſſa, p. 492. but the latter is ſo obſcure and erroneous, that it neither agrees with the plant, nor with the original manuſcript from which it was printed [u].

It was gathered at Vera Cruz by Dr. Houſtoun, who ſent ſeeds of it to Mr. Miller [x]. It was alſo found by Dr. Wright in Jamaica [y].]

18. Stalks ſlender, riſing to twenty feet high when ſupported, and dividing into many weak branches. Leaves four inches long and three broad, ending at their points in two horns, in ſome more acute than in others, ſeveral of them appearing as if cut a little hollow at the top, like thoſe of the Tulip-tree: they have three longitudinal veins, which join at the baſe of the leaf to the foot ſtalk, but the two outer diverge towards the borders of the leaf in the middle, drawing in again at the top; they are of a deep green on their upper ſide, but pale underneath, and ſtand on ſhort foot-ſtalks. Peduncles very ſlender, an inch and half long, purpliſh. Flowers, when expanded, not more than an inch and half in diameter, of a ſoft red colour, with little ſcent. Fruit ſmall, oval, when ripe purple.

Native of Jamaica; whence Dr. Houſtoun ſent the ſeeds to England.

[19. Stem ſuffrutеſcent at bottom, ſubdivided, angular, grooved. Leaves ſemiovate, three-nerved, veined, ſmooth on both ſides, marked behind longitudinally with pellucid dots: lobes terminated by very ſmall briſtles; the middle one a little larger than the others. Petioles ſhort, without glands. Tendrils filiform, very long. Stipules two, oppoſite, awl-ſhaped. Peduncles axillary, filiform, an inch long. Flowers nodding, pale green, rather large. Calycine ſegments ovate, acute, erect, concave, forming a goblet at the baſe. Petals ſemilanceolate, acute, erect, pale green. Crown ſimple; the ſegments awl-ſhaped, erect, converging, having tawny glands at the tip. Column longer than the corolla, round. Filaments awl-ſhaped, dilated. Germ roundiſh. Berry egg-ſhaped.—It is diſtinguiſhed from the other ſpecies by its rounded leaves ſlightly three-lobed at top only [z].

Jacquin obſerves, that the glandular dots on the under ſide of the leaf are ſix or ſeven in a longitudinal row along the inner ſide of the two lateral nerves; that the ſtipules are acuminate, ſhining, embracing, and reſembling bull's horns; that the peduncles are the ſame length with the leaves; that the flowers are middle-ſized and void of ſcent; that there is a three-leaved involucre; the leaflets ovate, concave, ſmall, firm,

[p] Gærtner. [q] Swartz. [r] Dillen. elth.
[s] Smith. [t] Linn. tranſ. [u] Smith. [x] Mant. dec. [y] Hort. kew. n. 9. [z] Swartz.

firm, ſhining, ſmooth, yelloviſh with a tinge of green; that the petals are white and twice as long as the calyx; the nectary multifid and yellow; that the berry is roundiſh, ſmall and juiceleſs; and that in moſt of the leaves the middle lobe is ſcarcely to be obſerved. He ſays it is very common in the woods about Carthagena in New Spain. Swartz found it in coppices on the ſouthern ſide of Jamaica; flowering at the beginning of the year. According to the Kew catalogue, it was introduced in 1786.

20. Native of the iſland of Jamaica[a].

21. This ſpecies was known to Linneus, who had never ſeen it, only by the deſcription of Feuillée. Cavanilles has given a figure of it from a plant which flowered in the royal garden at Paris[b]. It is a native of Peru.]

22. Root creeping, ſending up many weak ſtalks three or four feet high. Leaves ſhaped like thoſe of Ivy, and almoſt as large, but of a pale green and very thin conſiſtence. Peduncle ſlender, an inch and half long. Flowers dirty yellow, not larger than a ſixpence when expanded.

Native of Virginia and Jamaica. [Cultivated here in 1714. It flowers in may and june[c].

23. Native of Jamaica[d].

24. The whole plant is very ſmooth and even. Leaves glaucous underneath, undotted. Petioles furniſhed with two or four glands below the middle. Stipules acute, quite entire, more than half an inch in length. Calycine leaflets lanceolate, green underneath, whitiſh above, a little more than an inch in length. Petals lanceolate, blunt, white, the length of the calyx. Nectary ſhorter by half than the petals: rays violet, white at the tip. Flowers ſweet.

Native of Cayenne. Introduced in 1779, by Meſſ. Kennedy and Lee[e].

25. Stem twining, ſimple, becoming corky at the baſe with age, round, ſmooth. Leaves ſubpeltate, ſubcordate: lateral lobes almoſt horizontal; all acute, nerved, ſmooth on both ſides. Petioles ſhort, round, reflex, ſmooth. Glands two oppoſite, ſmall, ſeſſile, concave, brown, in the middle of the petioles. Stipules two, oppoſite, awl-ſhaped, by the ſide of the petioles. Tendrils long, between the petioles. Peduncles axillary, ſolitary, longer than the petioles, looſe, one-flowered. Flowers ſmall, whitiſh. Calyx none, except the flattiſh baſe of the corolla. Petals five, lanceolate, reflex at the tips. Nectary four-fold: inmoſt, a membranaceous rim, entire, brown, at the baſe of the column: inner one-leafed, plaited, crenate, duſky purple: outer ciliated with capillary erect hairs, black with yellow tips: outmoſt with cilias twice as long as the others, reflex, very dark purple, yellow from the middle to the tip. Column longer than the corolla. Germ roundiſh. Berry ſmall, blue, egg-ſhaped.

It is nearly allied to *P. ſuberoſa*; but differs in the lobes of the leaves being narrow and divaricated: the ſtem herbaceous, becoming like cork only when old; and the flowers ſmaller[f].

Mr. Sowerby remarks, that though this has its name from its ſmallneſs, there are others nearly if not quite as ſmall, and not well diſtinguiſhed; that ſeveral of them have no involucre, though there is a joint on the peduncle, or as he has it, between the peduncle and pedicel; and that they have but five petals, conſequently nothing that ſerves as a calyx.

He thus deſcribes the flower of this ſpecies: Peduncle cylindrical. Pedicel alſo cylindrical, curved a little, thickeſt at the flat baſe of the flower. Petals lanceolate, turned back. Principal rays cylindrical, ſpreading, curved back. Imperfect rays moſtly clubbed, ſometimes bifid. Operculum plaited and fringed at the edge. Nectary as in *lunata*, except that at the ridge of the protuberating bank are ſome ſmall, regular roundiſh glands or imperfect rays[g].

Native of Curaſſao[h], and Jamaica[i]. Introduced in 1690 by Mr. Bentick. It flowers in july[k].

26. Native of the Weſt Indies. Introduced about 1773. It flowers from june to ſeptember[l].]

27. This riſes with a weak ſtalk to the height of twenty feet. As the ſtalks grow old, they have a thick fungous bark like that of the Cork-tree, which cracks and ſplits. The ſmaller branches are covered with a ſmooth bark. Leaves ſmooth, on very ſhort petioles. The middle lobe is much longer than the lateral ones, ſo that the whole leaf is halbert-ſhaped. The flowers are ſmall, of a greeniſh yellow colour. Fruit egg-ſhaped, dark purple when ripe.

[Stem perennial. Flowers axillary, in pairs, white, apetalous. Leaves in the young plants peltate, but ſcarcely ſo when farther advanced; always ſhining, very ſmooth. Petioles without glands[m].

The fruit is thus deſcribed by Gærtner. Berry elliptic (an oblong ſpheroid, or ſhaped like an olive) very ſmooth, dark blue, filled with a watery pulp. Seeds twelve, obovate, mucronate at both ends, full of little pits, having an umbilical cord faſtened to it at one edge, ſhining, blackiſh. Acil membranaceous-pulpy, tranſparent, not peduncled, with the mouth obliquely truncated, toothleſs. Shell of the ſeed cruſtaceous, brittle. Albumen ſnow-white, full of pits like the ſhell. Embryo almoſt the length of the albumen.

Jacquin remarks that Plumier's figures do not agree with this plant.

Native of the Weſt Indies. Cultivated in 1759 by Mr. Miller. It flowers from june to ſeptember[n].]

28. The ſtalks riſe twenty feet high, dividing into many ſlender branches, covered with a ſoft hairy down. Leaves ſhaped like the point of a halbert, three inches long, and an inch and half wide at the baſe, light green, ſoft and ſilky to the touch, ſtanding obliquely to the footſtalks. Flowers not half ſo large as thoſe of the common or blue Paſſion-flower. Petals white. Rays purple with a mixture of yellow. Fruit ſmall, roundiſh, yellow when ripe. [The petioles have two oppoſite glands. Leaves ovate, tomentoſe on both ſides: lateral lobes ſhort; with an obſolete gland underneath behind the ſinus of the lobe[o].]

It was diſcovered by Dr. Houſtoun, growing naturally at La Vera Cruz: [and therefore was introduced before 1733, in which year he died. It flowers moſt part of the ſummer[p].

29. Native of the Weſt Indies. Introduced in 1778, by Mr. Gilbert Alexander. It flowers in ſeptember[q].]

30. Root annual, [or rather biennial.] The ſtalks riſe five or ſix feet high, when ſupported; they are channelled and hairy. The middle lobe of the leaf is three inches long, and one and a half broad; the two ſide-lobes are ſhort but broad; they are covered with ſhort brown hairs. Flowers on ſtrong hairy peduncles, two inches long. Calyx compoſed of ſlender hairy filaments, wrought like a net, longer than the petals, and turning up round them. They are white, and of ſhort duration. Fruit roundiſh-ovate, about the ſize of a golden Pippin, of a yelloviſh green colour, incloſed in the netted calyx. The whole plant has a diſagreeable ſcent when touched.

[The ſtipules are ciliary. The petioles have viſcid hairs but no glands. The involucre, (which Mr. Miller calls the calyx) reſembles that of *Nigella damaſcena*[r].

Berry oblong-ſpheroidal, pedicelled, villoſe, marked with three lines of a deeper colour longitudinally, green on the outſide, within ſilky white, membranaceous. Rind thin. Cavity empty, inflated. Seeds numerous, but ſcarcely twelve ripening in Europe, oblong-ſpheroidal, peduncled, hanging down from three lines in the ſhell of the berry. They are præmorſe and three-toothed at the top, in other parts compreſſed a little, pitted, of a dark cheſtnut colour. Covers three; the outmoſt pulpy, but becoming dry; the middle cruſtaceous, hard, brittle, deeply pitted; the inner membranaceous, white. Albumen ovate-oblong, truncated above, pitted and almoſt like a ſieve from the impreſſions of the middle coat: fleſhy, white. Embryo ſhorter by half than the albumen, milk-white. Cotyledons cordate-orbiculate, leafy,

[a] Swartz. [b] Smith ic. rar. [c] Hort. kew. [d] Swartz. [e] Hort. kew. [f] Swartz. [g] Linn. tranſ. [h] Linn. [i] Swartz. [k] Hort. kew. [l] Idem.

[m] Linn. ſpec. & ſyſt. [n] Hort. kew. [o] Linn. ſyſt. [p] Hort. kew. [q] Idem. [r] Linn. ſyſt.

very thin. Radicle ſhort, thicker outwards, centrifugal [t].]

It grows naturally in moſt of the iſlands of the Weſt Indies, where the Britiſh inhabitants call it *Love in a Miſt* [which is one vulgar name of *Nigella damaſcena*, that it reſembles in the involucre. It was cultivated by Mr. Miller in 1731; and flowers in july and auguſt.

31. Native of Jamaica. Cultivated in 1783, by Mrs. Norman [u]. It runs to a great height, and has dark-green gloſſy leaves; the involucrum is compoſed of three leaves divided into capillary ſegments, each terminating in a viſcid globule: the pillar ſupporting the germen is bright purple with darker ſpots: the petals are greeniſh on the outſide, and red within. The crown conſiſts of four rows of radii [x], which are varied with white and purple. The leaves of this ſpecies vary occaſionally, and Mr. Curtis ſuſpects it to be a variety of *P. fœtida*.]

32. Root perennial. Stalks annual, ſlender, riſing four or five feet high. At each joint one leaf, on a ſhort foot-ſtalk, having moſtly three oblong lobes, but the two ſide ones are ſometimes divided part of their length into two narrow ſegments, and thus becoming five-lobed; they are thin, of a light green, and ſlightly ſerrate. The flowers are produced from the joints of the ſtalk, at the foot-ſtalks of the leaves, on long ſlender peduncles, in ſucceſſion as the ſtalks advance in height during the ſummer months. Calycine leaflets oblong, blunt, pale green. Petals white, with a double circle of purple rays, the rays of the lower circle longeſt. The flowers have an agreeable ſcent, but are of ſhort duration, opening in the morning, and fading away in the evening. Fruit as large as a middling Apple, changing to a pale orange colour when ripe; incloſing many oblong rough ſeeds, lying in a ſweetiſh pulp.

It grows naturally in Virginia and other parts of North America, and was the firſt known in Europe of all the ſpecies, but was not very common in the Engliſh gardens till of late years.

[It was cultivated here in 1629, according to Parkinſon [y], who has given a good figure and deſcription of it, with a copy of the Jeſuite's ſophiſticated figure to contraſt with his own, and a copious abuſe of their attempts to deceive mankind.

33. Native of New Caledonia [z].

34. Stem angular, ſmooth. Leaves petioled, ſmooth on both ſides, veined underneath; lobes equal, divaricated, acute. Stipules in pairs, creſcent-ſhaped, embracing, acute at the top, toothed. Flowers ſolitary, peduncled, nodding, red; on round, pubeſcent peduncles. Calyx (or involucre) tubular, pubeſcent, three or five-cleft at the top, one-third of the length of the corolla. Corolla alſo tubular, the whole of it very ſoftly pubeſcent before it expands. Tube the length of the finger, round, pubeſcent. Border ten-cleft: ſegments ovate; the five outer (calyx) pubeſcent at the back, terminated by a filiform pubeſcent point below the tip; the five inner (petals) ſmooth, with a very ſmall point. Nectary very ſhort, in the throat. Column the length of the tube. Berry obovate, ſmooth.—Native of New Granada, whence it was ſent by Mutis.

Dr. Smith collects from this ſpecies and *P. adulterina*, that the flower of *Paſſiflora* is ten-petalled; and that what Linneus calls the involucre is the calyx. Juſſieu on the contrary calls the whole the calyx, and aſſerts the Paſſiflora to have no corolla. In moſt of the ſpecies the involucre cannot properly be regarded as a perianth, and even in this ſpecies it is permanent, and in the fruiting ſtate at a conſiderable diſtance from the fruit.]

35. This riſes in a few years to a great height with proper ſupport. It may be trained up more than forty feet high. The ſtalks will grow almoſt as large as a man's arm, and are covered with a purpliſh bark, but do not become very woody. The ſhoots often grow to the length of twelve or fifteen feet in one ſummer, and being very ſlender muſt be ſupported, otherwiſe they will hang to the ground, intermix with each other, and appear very unſightly. At each joint is one leaf compoſed of five ſmooth entire lobes; the middle one, which is longeſt, almoſt four inches long, and one inch broad in the middle, the others are gradually ſhorter, and the two outer lobes are frequently divided on their outer ſide into two ſmaller ones. Their foot-ſtalks are near two inches long, and have two embracing ſtipules at their baſe; and from the ſame point iſſues a long claſper or tendril. The flowers come out at the ſame joint with the leaves, on peduncles almoſt three inches long. The outer cover (or involucre) is compoſed of three concave ovate leaves, of a paler green than the proper leaves of the plant, and are little more than half the length of the calyx; the leaflets of which are oblong, blunt, pale green: the petals are nearly of the ſame ſhape and ſize, and ſtand alternately between them. Column about an inch long. Germ oval. Styles purpliſh, near an inch long. Rays of the crown in two circles; the inner, which is the ſhorteſt, inclines towards the column; the outer, which is near half the length of the petals, ſpreads open flat upon them, and is purple at bottom, but blue on the outſide. The flowers have a faint ſcent, and continue but one day. Fruit egg-ſhaped, the ſize and ſhape of the Mogul Plum, and when ripe, of the ſame yellow colour, incloſing a ſweetiſh diſagreeable pulp, in which are lodged oblong ſeeds.

[Linneus remarks, that the petioles have two glands on them, and the ſtipules are creſcent-ſhaped [a].

Peduncle cylindrical, ſwelling a little at the baſe. Pedicel alſo cylindrical, thickening at each end. The outer five or ſix petals (or calycine leaflets) a little fleſhy, oblong, rather obtuſe; inner narrower and thinner, about the ſame length. Principal rays of the crown in two rows horizontal, thread-like, a little pointed, nearly alike, under each other. Imperfect rays in one regular row, with roundiſh heads, on little footſtalks ſtanding erect on an horizontal elevated plane at the baſe of the principal rays: within theſe imperfect rays are a very different ſet, entire at the inſertion, divided into threads about half way down, and inclining againſt the column. On the under ſide is a protuberance, which catches the margin of the operculum; and that ſpreads from the column under the aforeſaid rays. Nectary round the baſe of the column, with a thick protuberance round the ſide of the lower part of the flower, on which reſts the operculum and which almoſt divides it into two cells [b].]

There is a variety of this with much narrower lobes, divided almoſt to the bottom. The flowers come later in the ſummer; the petals are narrower, and of a purer white.

There is a variety alſo of the *fœtida*, (n. 30.) if it is not a diſtinct ſpecies, with hairy narrower lobes. The whole leaf is ſhaped more like the point of a halbert, and the upper ones having very ſmall indentures, approach to ſimple leaves without lobes. The flowers are alſo ſmaller, but of the ſame form, and the roots are of a ſhorter duration.

The blue Paſſion-flower grows naturally in Brazil. Being hardy enough to thrive in the open air, it is now become the moſt common ſpecies in England, [though it was introduced long after the *incarnata*. It was cultivated in 1699, by the Dutcheſs of Beaufort [c].

36. Stems woody. At each knot, about half a foot diſtant, a ſingle leaf, nearly the ſize of the hand extended, ſmooth, divided into ſeven lobes, which widen towards the end, acuminate, reaching almoſt to the petiole, which is four or five inches in length. A tendril and a flower come out from the ſame point with the leaf. Peduncle two inches long. The flower is incloſed in an involucre, and together are larger than a hen's egg. The involucre opens into three equal whitiſh leaves, dotted on the inſide, and ſtreaked with

[t] Gærtner. [u] Hort. kew.
[x] Mr. C. probably means by this that the crown is marked by four circles alternately purple and white.
[y] Hort. kew. [z] Forſter.
[a] Syſt. [b] Sowerby in Linn. tranſ. [c] Hort. kew.

a few purple veins. The lower half of the flower when expanded reſembles a cup with a pentagon rim, white on the inſide, hairy at bottom; the hairs very ſhort, with a little red gland at top: it is furrounded with a double fringe, the threads of which are a line in thickneſs, tender and pointed, almoſt ſquare and contiguous: the outer row an inch and half long, the inner an inch; all white towar ls the end, thence violet to the middle, the lower part pale; adorned with five bands; ſtanding right up: the inner row is a little more depreſſed, but has the ſame colour and conſiſtence with the outer. The corolla is compoſed of ten violet-coloured petals in two rows, five in each, the inner much narrower than the outer, all an inch and half long, with a ſmall point at the end verging outwards. In the centre of the cup is a ſort of baſe, of a cylindrical form, from three to four lines in thickneſs, excavated with a little trench, and furrounded by many very ſhort hairs of a ruſſet colour. * On this is placed the column, which is white, ſmall, perfectly round, eight or nine lines in height, and a line and half in diameter. Fruit the ſize of an Orange, round, poliſhed, like that of Coloquintida, except that next the peduncle it is drawn out like a Pear. It is filled with a white mucilaginous pulp, containing many ſeeds, a little larger than grains of wheat, oval, a little compreſſed, pointed at one end, hardiſh, ſhining, hairy.—Native of the iſland of Martinique.

37. Stems angular. Leaves pedate; a petiole two or three inches long, being divided into three others ſhorter and more ſlender, the middle ſuſtaining one leaf only larger than the reſt, the two others forked, the leaflet next the middle one of the ſame form but ſmaller, the outer ſtill ſmaller, cut to the baſe, but the ſegment next the petiole reſembling rather an earlet than a leaflet: each taken ſeparately is ſomewhat like a bay-leaf: they are all toothletted, ſmooth, ſhining, bright green, paler underneath: the middle leaflet is four inches long, and almoſt two wide; the leaſt is not more than an inch in length, and half an inch in width. The flowers are a little larger than thoſe of the preceding. The rays of the crown are very cloſe, deep red with two or three white rings, very ſlender at the end and violet; they are twiſted ſo as to reſemble the ſerpents about Meduſa's head. The five inner parts of the corolla are entirely blue; the five outer pale green within with abundance of little red dots, on the outſide clear green. The three leaves of the involucre are hollowed out like the bowl of a ſpoon, fringed all round, deep green, with many ribs underneath. Fruit the ſize and form of a middling Apple: rind regular and ſmooth, of a ſhining green colour, with ſtill brighter dots.

Native of the iſland of Dominica [b], and other iſlands of the Weſt Indies. Introduced in 1781, by Mr. Francis Maſſon [c].

The following diſtinctions, however incomplete, may aſſiſt in diſcriminating the ſpecies. The Stem is round in n. 2. 8. 9. 13. 16. 25. 32. 36. Angular in n. 11. 14. 15. 17. 19. 34. 37. Triangular in n. 3. 5. 12. Quadrangular in n. 6. The Leaves in moſt of the ſpecies are alternate: in n. 2. they are oppoſite. They vary in form: in n. 19. they are roundiſh: in many, the leaves or leaflets are ovate, as in n. 1. 2. 3. 8. 12. 15. 23. 28.: oblong in n. 9. 18. 21. 29.: oblong-oval in n. 11.: cordate in n. 4. 5. 6. 7. 12. 13. 18. 22. 24. 25. 30.: creſcent-ſhaped in n. 16. 17.: palmate five-lobed in n. 35.: palmate ſeven-lobed in n. 36.: pedate in n. 37.: in general the leaves or lobes are entire on the edge, but in n. 1. 36. 37. they are ſerrate. The Petioles in many ſpecies have a pair of glands on them, as in n. 2. 3. 5. 7. 8. 23. 25. 26. 28. 29. 32. 35.: in n. 3. they are ſcarcely viſible: in n. 24. there are ſometimes two, and ſometimes four glands: n. 6. has ſix glands: in n. 4. 12. 13. 14. 15. 16. 17. 19. 22. the petiole is naked: and in n. 16. 17. the leaves themſelves are glandular near the baſe.

The Flowers in moſt of the ſpecies are ſolitary, or come out ſingly from the axil of a leaf: but in n. 2. 15. 17. 27. they come out two together; and in n. 9. ſeveral together. Their colours are various. Pale in n. 2. 14. 19. 27. White in n. 16. 30. White and pale red in n. 13. 32. White and blue in n. 9. 24. White red and blue in n. 5. 6. 7. 8. White green and yellow in n. 17. White purple and yellow in n. 25. 28. White purple and blue in n. 36. Red in n. 18. 34. Scarlet in n. 12. 15. Red green and blue in n. 37. Purple in n. 3. 11. Yellow in n. 22. Theſe colours take in the rays, and as uſual are by no means certain. The Crown, which conſtitutes great part of the ſingular beauty of this flower in many ſpecies, is ſingle in n. 12. 19. double in n. 32. 35. triple in n. 3. 8. 13. 16. 17. quadruple in n. 25. and quintuple in n. 6. 7. In n. 16. it is very long; and in n. 11. 34. it is very ſhort. N. 30. is diſtinguiſhed from all the reſt by its capillary-multifid involucre, reſembling that of Devil-in-a-buſh.

The Fruit in moſt of the ſpecies is egg-ſhaped, more or leſs prolonged. It is obovate in n. 34.: ſpherical in n. 13. 14.: roundiſh in n. 5. 12. 28. 32. 36. 37. It is of various colours: purple in n. 3. 12. 14. 18. 27.: fleſh-coloured in n. 15.: ſcarlet in n. 18.: pale orange in n. 32.: yellow in n. 5. 8. 9. 28. 35.: greeniſh yellow in n. 6. 30. 36.: green in n. 37.: blue in n. 25.: ſpotted in n. 11.

Theſe beautiful plants were unknown till the diſcovery of America. They are found in various parts both of the Continent, chiefly of South America, and of the Iſlands. N. 35. is found in Brazil: n. 24. in Cayenne: n. 3. in the Bahama iſlands: n. 22. and 32. in Virginia.]

PROPAGATION AND CULTURE.

All the perennial ſorts which are natives of the hot parts of America, require a ſtove to preſerve them here, without which they will not thrive; for although ſome of the ſorts will live in the open air during the warm months in ſummer, yet they make but little progreſs; nor will the plants produce many flowers, unleſs the pots in which they are planted are plunged into the tan-bed of the ſtove, and their branches are trained againſt an eſpalier. The beſt way to have them in perfection, is to make a border of earth at the back of the tan-bed, which may be ſeparated by planks to prevent the earth from mixing with the tan; and when the plants are ſtrong enough, they ſhould be turned out of the pots, and planted in this border; adjoining to which, ſhould be a trellis erected to the top of the ſtove; againſt this the ſtalks muſt be trained, and as they advance they will form a hedge to hide the wall of the ſtove, and their leaves continuing green all the year, together with their flowers, which will be plentifully intermixed in ſummer, will have a very agreeable effect.

As there will be only a plank partition between the earth and the tan, the earth will be kept warm by the tan-bed, which will be of great ſervice to the roots of the plants. This border ſhould not be leſs than two feet broad and three deep, which is the uſual depth of the pit for tan; ſo that where theſe borders are intended, the pits ſhould not be leſs than eight feet and a half or nine feet and a half broad, that the bark-bed, excluſive of the border, may be ſix and a half or ſeven feet wide. If the border is fenced off with ſtrong ſhip planks, they will laſt ſome years, eſpecially if they are well painted over with a compoſition of melted pitch, brick-duſt and oil, which will preſerve them ſound a long time; and the earth ſhould be taken out carefully from between the roots of the plants, at leaſt once a year, putting in freſh; with this mangement, I have ſeen theſe plants in great perfection. But where there has not been this conveniency, I have turned the plants out of the pots, and planted them into the tan-bed when it was half rotten, into which they have rooted exceedingly, and have thriven for two or three years as well as could be deſired, but when their roots extended to a great diſtance in the tan-bed, they have been injured by renewing the bark; and when it has fermented pretty violently, the roots have been ſcalded, and the plants have been killed, ſo that the other method is more eligible.

Theſe plants are propagated by ſeeds, which ſhould be ſown upon a good hot-bed in the ſpring, and when the

[b] Plumier. [c] Hort. kew.

the plants are fit to remove, they ſhould be each planted in a ſmall pot filled with good kitchen-garden earth, and plunged into a bed of tanner's bark, obſerving to ſhade them from the ſun till they have taken new root; then they muſt be treated like other tender plants from the ſame countries. When they are too high to remain under the glaſſes of the hot-bed, they ſhould be turned out of the pots and planted in the ſtove, in the manner before mentioned.

As theſe plants do not often perfect their ſeeds here, they may be propagated by laying down their branches, which, if done in april, they will put out roots by the middle of auguſt, when they may be ſeparated from the old plants, and either planted in pots to get ſtrength, or into the border of the ſtove, where they are to remain.

Some of theſe ſorts may alſo be propagated by cuttings; theſe ſhould be planted into pots about the middle or latter end of march, and plunged into a moderate hot-bed, obſerving to ſcreen them from the ſun, and refreſh them with water gently, as often as the earth may require it; and in about two months or ten weeks, they will put out roots, and may then be treated as the ſeedling plants.

22. The Yellow Paſſion-flower may be propagated by its creeping roots, parted in april, and planted where they are to remain. This will live in a warm border, if treated as directed for n. 32. It lived many years in a ſouth-weſt border in the Cheſſea garden, but in the year 1740 all the plants were killed by the froſt.

30. Is propagated by ſeeds, ſown upon a hot-bed early in the ſpring. When the plants are fit to be removed, tranſplant each into a ſmall pot filled with light kitchen-garden earth; plunge them into a hot-bed again, and ſhade them from the ſun till they have taken new root. Shift them into larger pots as the roots increaſe; and when the plants are too tall to remain in the hot-bed, remove them into an airy glaſs-caſe; admitting air in warm weather but ſcreening them from cold. In this ſituation the plants will flower in july, and the ſeeds ripen in autumn.

32. This ſort is uſually propagated by ſeeds which are brought from America, for the ſeeds do not often ripen in England; though I have ſometimes had ſeveral fruit perfectly ripe on plants, which were plunged in a tan-bed under a deep frame; but thoſe plants which are expoſed to the open air, do not produce fruit here. The ſeeds ſhould be ſown upon a moderate hot-bed, which will bring up the plants much ſooner than when they are ſown in the open air, ſo that they will have more time to get ſtrength before winter.

When the plants are come up two or three inches high, they ſhould be carefully taken up, and each planted in a ſeparate ſmall pot filled with good kitchen-garden earth, and plunged into a moderate hot-bed to forward their taking new root; after which they ſhould be gradually inured to bear the open air, to which they ſhould be expoſed in ſummer, but in the autumn they muſt be placed under a garden-frame to ſcreen them from the froſt, but they ſhould have the free air at all times in mild weather. The ſpring following ſome of theſe plants may be turned out of the pots, and planted in a warm border, where, if they are covered with tanner's bark every winter to keep out the froſt, they will live ſeveral years, their ſtalks decaying in the autumn, and new ones ariſing in the ſpring, which in warm ſeaſons will flower very well. If thoſe plants which are continued in pots are plunged into a tan-bed, ſome of them may produce fruit; and, if the ſtalks of theſe are laid down in the beginning of june, into pots of earth plunged near them, they will take root by the end of auguſt.

35. The common or blue Paſſion-flower may alſo be propagated by ſeeds, which ſhould be ſown in the ſame manner as thoſe of the thirty-ſecond ſort, and the plants treated in the ſame way till the following ſpring, when they ſhould be turned out of the pots, and planted againſt a good aſpected wall, where they may have height for their ſhoots to extend, otherwiſe they will hang about and entangle with each other, ſo as to make but an indifferent appearance; but where buildings are to be covered, this plant is very proper for the purpoſe. After they have taken good root in their new quarters, the only care they will require, is to train their ſhoots up againſt the wall, as they extend in length, to prevent their hanging about, and if the winter proves ſevere, the ſurface of the ground about their roots ſhould be covered with mulch to keep the froſt from penetrating the ground; and if the ſtalks and branches are covered with mats, peas-haulm, ſtraw, or any ſuch light covering, it will protect them in winter againſt ſevere froſts; but this covering muſt be taken off in mild weather, otherwiſe it will cauſe the branches to grow mouldy, which will be more injurious to them than the cold. In the ſpring the plants ſhould be trimmed, when all the ſmall weak ſhoots ſhould be entirely cut off, and the ſtrong ones ſhortened to about four or five feet long, which will cauſe them to put out ſtrong ſhoots for flowering the following year.

This plant is alſo propagated by laying down the branches, which in one year will be well rooted, may be taken off from the old plants, and tranſplanted where they are deſigned to remain. The cuttings of this will alſo take root, if they are planted in a loamy ſoil not too ſtiff, in the ſpring, before they begin to ſhoot. If theſe are covered with bell or hand-glaſſes to exclude the air, they will ſucceed much better than when they are otherwiſe treated; but when the cuttings put out ſhoots, the air ſhould be admitted to them, otherwiſe they will draw up weak and ſpoil, and they muſt be afterwards treated as the layers. Thoſe plants which are propagated by layers or cuttings, do not produce fruit ſo plentifully as the ſeedling plants; and I have found the plants which have been propagated two or three times, either by layers or cuttings, ſeldom produce fruit, which is common to many other plants.

If in very ſevere winters the ſtalks of theſe plants are killed to the ground, the roots often put out new ſtalks the following ſummer, therefore they ſhould not be diſturbed; and where there is mulch laid on the ground about their roots, there will be little danger of their being killed, although all the ſtalks ſhould be deſtroyed.

Leaves pinnate and bipinnate, leaflets gaſhed at the baſe in front.

DESCRIPTIONS, *&c.*

[1. Root biennial, thick, milky. Stem ſtiff, rugged, grooved and angular, branched from the bottom, almoſt the height of a man, when cut yielding a fetid, rue like, whitiſh, tenacious gum. Branches numerous, panicled. Root-leaves cordate, of different ſizes, ſeldom lobed, netted-ſcabrous, acutely crenate; petiole angular above. The firſt (or lower ſtem-leaves) ternate, with the lateral leaflets ſeſſile and obliquely ovate, the end leaflet petioled, cordate, three-lobed or five-lobed. The ſecond (or upper ſtem-leaves) quinate (or pinnate with two pairs of lobes and an odd one), but very like the others; the leaflets three inches long, with ſharp notches terminating in a white point, but ſometimes obliterated. Nerves of the terminating leaflet always oppoſite, but in the lateral leaflets ſcattered. The uppermoſt leaves are quite ſimple, cordate-ovate, lobed, like thoſe of the Fig. All the branch-leaves wedge-ſhaped, quite entire from the baſe to the middle; thence to the tip acutely-crenate, an inch long, on a petiole of the ſame length. Umbels very numerous, commonly with ten rays; the principal one terminating the ſtem: at the baſe of this are two, three or four branches, whence the top of the ſtalk becomes as it were proliferous. Seed ſuborbiculate, about three lines in diameter [a].

According to Linnæus, the ſtem is ſmooth and even, a foot and half high and more. Leaves cordate, ſometimes lobed, ſtiffiſh, wrinkled, ſhining, acutely notched or ſerrate. Petals yellow, entire, acute, bent in. Seeds compreſſed, orbiculate [b].

Native of the South of Europe. Introduced in 1771, by Monſ. Richard. It flowers in june and july [c].

2. The Wild Parſnep has a biennial, ſimple, whitiſh root, putting forth ſome large fibres from the ſide. Stem ſingle, three or four feet high, erect, rigid, angular, pubeſcent, hollow, branched. Leaves alternate, ſmaller than thoſe of the garden Parſnep and of a darker green; in open ſituations pubeſcent, eſpecially the root-leaves. Flowering-branches come out from the axils of the leaves from top to bottom, ſupporting umbels which are ſmaller than that which terminates the ſtem. Flowers ſmall, yellow, with inflex regular petals. There is no involucre either general or partial [d]. Dr. Withering ſays, that there is ſometimes an involucel of one leaf. He adds, that the ſtem is membranaceous at the corners, that the rays of the umbel are from ſix to twelve; thoſe of the umbellets ſhort and numerous. Mr. Relhan remarks, that the petioles are pubeſcent; the leaflets very ſoft, ſerrate, and frequently three-lobed; the univerſal umbel conſiſting of ten rays or more; the partial of twenty and upwards.

Gærtner obſerves that there are ſometimes a few leaflets under the univerſal umbel. He deſcribes the ſeeds as middle-ſized, elliptic or obovate, ſlightly emarginate above, leafy-compreſſed, pale ſtraw-coloured, in the freſh ſeeds mixed with purple: back very ſlightly convex, with three capillary ſtreaks in the middle, and another more raiſed near the edge: rim narrow, thin: belly flat, with two ferruginous bowed long fillets, but not reſembling *Ferrum equinum*, as in *Sphondylium*, but at the baſe converging inwards and acuminate.

Wild Parſnep is native of moſt parts of Europe, on the borders of ploughed fields and on the banks of hedges, chiefly in a calcareous or marly ſoil. It flowers from the end of june through auguſt.]

β. Garden Parſnep has ſmooth leaves, of a light or yellowiſh green colour, in which it differs from the wild plant; the ſtalks alſo riſe higher, and are deeper channelled; the peduncles are much longer, and the flowers of a deeper yellow colour.

[Retzius remarks, that it has pinnate and ſubpinnate leaves with ear-like appendages; but this, I preſume, applies both to the wild and garden plant. He adds, that α, that is, the wild Parſnep, is ſmooth; and β, that is, the garden Parſnep, hairy. Which is directly contrary to what Mr. Miller affirms. The truth is, that the wild plant is ſometimes ſmooth, but more often hairy; and the garden plant ſometimes hairy, but generally ſmooth.

The roots are ſweeter than Carrots, and are much eaten by thoſe who abſtain from animal food in Lent, or eat ſalt-fiſh on faſt-days: they are highly nutritious. In the north of Ireland they are brewed, inſtead of malt, with hops, and fermented with yeaſt. The liquor thus obtained is agreeable. Hogs are fond of theſe roots, and quickly grow fat with them [e].

Old Gerarde ſays, "there is a good and pleaſant "food or bread made of the roots of Parſneps, as "my friend maſter Plat hath ſet forth in his book "of experiments."

It is aſſerted, ſays Ray, by ſome of our writers, that the roots, when old, bring on delirium and madneſs, and hence are called *Madneps*.

Parkinſon, after informing us that the ſeed ripens the ſecond year after ſowing, adds; "if they do "flower the firſt year, the countrey people call them "madde Neepes."

Allione obſerves, that although the old roots of the *wild* Parſnep be hot and acrimonious, yet we are not to attribute to them the bad effects which ſome affirm them to have.

The ſeeds contain an eſſential oil, and will often cure intermittent fevers [f]. The ſeeds uſed in medicine ſhould be thoſe of the wild plant] but the druggiſts commonly ſell the ſeed of the garden kind for it, which they may purchaſe at an eaſy price when it is too old to grow.

[Villars ſays that they have two remarkable varieties of the Wild Parſnep in Dauphiné; one with an angular branched ſtem approaching very near to the Garden Parſnep; the other with a ſimple round ſtem, very ſlightly ſtriated, and receding ſo far from the cultivated plant, that it ſeems to be a diſtinct ſpecies.

3. Root perennial, as thick as the human arm, yellow, branched; the branches an inch or an inch and half in thickneſs, a foot and half in length, tubercled, with a corky bark. Stem from three feet to the height of a man, the thickneſs of a finger, ſtriated, covered at the baſe with ſcariofe membranaceous ſcales, like the Ferns; in other parts very ſmooth and ſhining; angular at top, eſpecially at the branches. Primary (or root) leaves quite ſimple, cordate, acutely crenate; the others ternate or quinate, with the end

[a] Gouan. [b] Mant. [c] Hort. kew. [d] Ray hiſt. [e] Withering. [f] Idem.

leaflet always cordate and very large; the lateral ones obliquely cordate, with the upper lobe ſhorter. The loweſt ſtem-leaves more compound, conſidered as a whole triangular, two feet long, bipinnate, having five pinnules on each ſide; the loweſt pinna pinnate, commonly with five leaflets, the end one cordate, the reſt ſeſſile and obliquely cordate: the leaflets are an inch to two inches long; the other pinnules are firſt ternate, then ſimple. The other ſtem-leaves decreaſe, and are firſt quinate, next ternate, and at the branches ſimple. Petiole of the root-leaves from the ſheath to the firſt pinna flattiſh above and thence angular-keeled; on the contrary that of the branch-leaves is furrowed. Sheaths wide ſtriated, in the root-leaves very ſtrigoſe; in the ſtem-leaves ſmooth. All the leaflets are hairy, eſpecially at the back. At the flowering-branches there are ſpathaceous ſheaths, which are naked or deſtitute of leaves. The umbelliferous branches are very ſmooth; firſt alternate, erect, then two, three, or four together in a ſort of whorl, two or three inches long, with one or two ſpathaceous leaflets towards the middle or at the top. The univerſal umbels have uſually ſeven or eight rays, an inch long, of a yellowiſh green colour. Involucres with from four to ſix leaflets, ſcarcely more than a line in length: the involucels have as many. Fruits flat, with the rim thicker, three or four lines in diameter, and a little longer. The involucres and involucels are frequently permanent. Juice yellow, bearing no marks of a reſinous or aromatic principle [x].]

This juice flows out where either the leaf or ſtalk is broken. They are both very rough; the former dark green, the latter ſeven or eight feet high. The ſtalks divide towards the top into many horizontal branches, each terminated by a large umbel of yellow flowers. They appear in july.

[Native of the South of Europe, South of France, Italy and Sicily. Cultivated in 1731 by Mr. Miller [y].

This plant commonly ripens its ſeeds with us, and its juice manifeſts ſome of the qualities diſcovered in the officinal Opopanax: but it is only in the warmer regions of the Eaſt, where this plant is alſo a native, that the juice concretes into this gum-reſin. It is obtained by means of inciſions made at the bottom of the ſtalk: and is imported from Turkey and the Eaſt Indies ſometimes in little round drops or tears, but more commonly in irregular lumps, of a reddiſh yellow colour, ſpecked with white on the outſide; internally paler, and frequently variegated with large white pieces.

This gum-reſin has a ſtrong diſagreeable ſmell, and a bitter, acrid, ſomewhat nauſeous taſte. It readily forms a milky liquor with water by rubbing; and this on ſtanding depoſits a portion of reſinous matter, and becomes yellowiſh: to rectified ſpirit it yields a gold-coloured tincture, which taſtes and ſmells ſtrongly of the drug. Water diſtilled from it is impregnated with its ſmell, but no eſſential oil is obtained on committing moderate quantities to the operation.

Opopanax has been long eſteemed for its attenuating, deobſtruent and aperient virtues; but as it is commonly preſcribed in combination with other medicines, theſe qualities are by no means aſcertained, nor do its ſenſible qualities indicate it to be a medicine of much power. Dr. Cullen claſſes it with the anti-ſpaſmodics; it is however leſs fetid than galbanum, though more ſo than ammoniacum. It has commonly been given in hypochondriacal affections, viſceral obſtructions, menſtrual ſuppreſſions, and aſthmas, eſpecially when connected with a phlegmatic habit of body. In the London Pharmacopœia it is directed in the *pillulæ e gummi* [z].]

PROPAGATION AND CULTURE.

2. The Parſnep is cultivated in kitchen-gardens, the roots being large, ſweet, and accounted very nouriſhing. It is propagated by ſeeds, which ſhould be ſown in february or march, in a rich mellow ſoil, well dug, that their roots may run downwards, the greateſt excellency being the length and bigneſs of the roots. Theſe may be ſown alone, or with Carrots, as is practiſed by the kitchen-gardeners near London; ſome of whom alſo mix Leeks, Onions, and Lettuce, with their Parſneps; but this I think very wrong, for it is not poſſible, that ſo many different ſorts can thrive well together, except they are allowed a conſiderable diſtance; and if ſo, it will be equally the ſame to ſow the different ſorts ſeparate. However, Carrots and Parſneps may be ſown together very well, eſpecially where the Carrots are deſigned to be drawn off very young; becauſe the Parſneps generally ſpread moſt towards the end of the ſummer, when the early Carrots are gone.

When the plants are come up, hoe them out to ten or twelve inches aſunder, cutting up all the weeds. This muſt be repeated three or four times, according as you find the weeds grow; but in the latter part of ſummer, when the plants cover the ground, they will prevent the growth of weeds.

When the leaves begin to decay, the roots may be dug up for uſe. Before this they are ſeldom well taſted; nor are they good for much in the ſpring, after they are ſhot out again. To preſerve them for this ſeaſon, dig them up the beginning of february, and bury them in ſand in a dry place, where they will remain good until the middle of april or later.

To ſave ſeeds make choice of ſome of the longeſt, ſtraighteſt and largeſt roots, and plant them two feet aſunder, where they are defended from ſtrong ſouth and ſouth-weſt winds, for the ſtems grow to a great height; keep them clear from weeds, and if the ſeaſon ſhould prove dry, water them twice a week. At the end of auguſt or the beginning of ſeptember, the ſeeds will be ripe: then carefully cut off the umbels, and ſpread them upon a coarſe cloth for two or three days to dry; after which, beat off the ſeeds and put them up for uſe. Never truſt to the ſeeds that are more than a year old, for they will ſeldom grow beyond that age.

The leaves are dangerous to handle, eſpecially in a morning, while the dew remains upon them. I have known gardeners, when they have been drawing up Carrots from among Parſneps, when their leaves were wet with dew, and have turned the ſleeves of their ſhirts up to their ſhoulders, have their arms covered with large bliſters, full of a ſcalding liquor, which have proved very troubleſome for ſeveral days.

[To cultivate Parſneps for the farmer ſow the ſeed in autumn, ſoon after it is ripe; by which means the plants will come on early the following ſpring, and will get ſtrong before the weeds can grow ſo as to injure them. The young plants never materially ſuffer through the ſeverity of the ſeaſons.

The beſt ſoil for them is a rich deep loam; next to this is ſand, or they will thrive well in a black gritty ſoil; but will never pay for cultivating in ſtone braſh, gravel or clay ſoils; and they are always the largeſt where the ſtaple is deepeſt. If the ſoil be proper, they do not require much manure. A very good crop has been obtained for three ſucceſſive years without any. Forty cart-loads of ſand laid on an acre of very ſtiff loam, and ploughed in, has anſwered very well.

Sow the ſeed in drills eighteen inches diſtant, that the plants may be horſe or hand-hoed: they will be more luxuriant if they have a ſecond hoeing, and are carefully earthed ſo as not to cover the leaves.

If land cannot be got in proper condition to receive the ſeed in autumn, ſow a plat in the garden or the corner of a field, and tranſplant thence at the end of april or early in may. The plants muſt be carefully drawn, and the land that is to receive them well pulverized by harrowing and rolling. When it is thus in order, open a furrow ſix or eight inches deep, and lay the plants in it regularly at the diſtance of ten inches or a foot, taking care not to let the root be bent, and that the plant ſtand upright after the earth is cloſed about it, which ſhould be done immediately by perſons following the planter with a hoe, and who muſt be attentive not to cover the leaves. Open another furrow eighteen inches diſtant from the laſt, plant it as before, and ſo proceed till the field is completely cropped. When any weeds appear, hoe the ground, and earth the plants.

[x] Gouan. [y] Hort. kew. [z] Woodville.

Dibbling in Parſneps is a bad method, as the ground thereby becomes ſo bound as not eaſily to admit the lateral fibres, with which the root of this plant abounds, to fix or work in the earth, on which account the roots never attain their proper ſize.

With attention to the ſoil, the ſeaſon for ſowing, cleaning and earthing the plants, and raiſing the ſeed from the largeſt and beſt Parſneps, there is no doubt but the crop would anſwer much better than a crop of Carrots. They are equal to them if not ſuperior in fatting pigs; for they make the fleſh whiter, and the animals eat them with more ſatisfaction. Clean waſhed and ſliced among bran, horſes eat them greedily, and thrive with them; nor do they heat horſes, or like Corn fill them with diſorders*.

In France, and our iſlands adjoining to it, Parſneps are held in high eſteem both for cattle and ſwine. In Brittany this crop is ſaid to be little inferior in value to Wheat. Milch cows fed with it in winter give as much and as good milk, and yield butter as well-flavoured, with Parſneps, as with Graſs in may or june*.

t. 3. The two other ſpecies may be propagated from ſeeds, and are hardy enough to bear the open air in our climate.

PASTURE.

Paſture ground is of two ſorts: the one is low meadow land, which is often overflowed, and the other is upland, which lies high and dry. The firſt of theſe will produce a much greater quantity of hay than the latter, and will not require manuring or dreſſing ſo often; but then the hay produced on the upland is much preferable to the other, as is alſo the meat which is fed in the upland more valued than that which is fatted in rich meadows; though the latter will make the fatter and larger cattle, as is ſeen by thoſe which are brought from the low rich lands in Lincolnſhire. But where people are nice in their meat, they will give a much larger price for ſuch as has been fed on the downs, or in ſhort upland Paſture, than for the other, which is much larger. Beſides this, dry Paſtures have an advantage over the meadows, that they may be fed all the winter, and are not ſo ſubject to poach in wet weather; nor will there be ſo many bad weeds produced, which are great advantages, and do, in a great meaſure, recompenſe for the ſmallneſs of the crop.

I have already mentioned the advantages of meadow land, or ſuch as is capable of being overflowed with water, and given directions for draining and improving low Paſture land; therefore ſhall not repeat what is there ſaid, but juſt mention ſome methods for improving upland Paſture.

The firſt improvement of upland Paſture is, by fencing it, and dividing it into ſmall fields of four, five, ſix, eight, or ten acres each, planting timber-trees in the hedge rows, which will ſcreen the Graſs from the drying pinching winds of march, which prevent the Graſs from growing in large open lands; ſo that if april prove a cold dry month, the land produces very little hay; whereas in the ſheltered fields the Graſs will begin to grow early in march, and will ſoon after cover the ground, and prevent the ſun from parching the roots of the Graſs, whereby it will keep growing, ſo as to afford a tolerable crop, if the ſpring ſhould prove dry. But in fencing land, it muſt be obſerved not to make the incloſures too ſmall, eſpecially where the hedge rows are planted with trees; becauſe when the trees are advanced to a conſiderable height, they will ſpread over the land; and, where they are cloſe, will render the Graſs ſour; ſo that inſtead of being an advantage, it will greatly injure the Paſture.

The next improvement of upland Paſture is, to make the turf good, where, either from the badneſs of the ſoil, or want of proper care, the Graſs has been deſtroyed by ruſhes, buſhes, or mole-hills. Where the ſurface of the land is clayey and cold, it may be improved by paring it off, and burning it: but if it is a hot ſandy land, then chalk, lime, marle, or clay, are very proper manures to lay upon it; but this ſhould be laid in pretty good quantities, otherwiſe it will be of little ſervice to the land.

If the ground is over-run with buſhes or ruſhes, it will be of great advantage to grub them up towards the latter part of the ſummer, and after they are dried to burn them, and ſpread the aſhes over the ground juſt before the autumnal rains; at which time the ſurface of the land ſhould be levelled, and ſown with Graſs-ſeed, which, if done early in the autumn, will come up in a ſhort time, and make good Graſs the following ſpring. So alſo, where the land is full of mole-hills, theſe ſhould be pared off, and either burnt for the aſhes, or ſpread immediately on the ground, where they are pared off, obſerving to ſow the bare patches with Graſs-ſeed, juſt as the autumnal rains begin.

There are ſome Paſture lands which are full of ant-hills, which are not only diſagreeable to the ſight, but where they are in any quantity, the Graſs cannot be mowed; therefore the turf which grows over them ſhould be divided with an inſtrument into three parts, and pared off each way; then the middle or core of the hills ſhould be dug out and ſpread over the ground, leaving the holes open all the winter to deſtroy the ants, and in the ſpring the turf may be laid down again, and after the roots of the Graſs are ſettled again in the ground, it ſhould be rolled to ſettle the ſurface, and make it even. If this is properly managed, it will be a great improvement to ſuch land.

Where the land has been thus managed, it will be of great ſervice to roll the turf in the months of february and march, with a heavy wood roller, always obſerving to do it in moiſt weather, that the roller may make an impreſſion: this will render the ſurface level, and make it much eaſier to mow the Graſs, than when the ground lies in hills; and will alſo cauſe the turf to thicken, ſo as to have what the people uſually term a good bottom. The Graſs likewiſe will be the ſweeter for this huſbandry, and it will be a great help to deſtroy bad weeds.

Another improvement of upland Paſture is the feeding them every other year; for where this is not practiſed, the land muſt be manured at leaſt every third year; and where a farmer has much arable land, he will not care to part with his manure to the Paſture. Therefore every farmer ſhould endeavour to proportion his Paſture to his arable land, eſpecially where manure is ſcarce, otherwiſe he will ſoon find his error; for the Paſture is the foundation of all the profit, which may ariſe from the arable land.

Whenever the upland Paſtures are mended by manure, there ſhould be a regard had to the nature of the ſoil, and a proper ſort of manure applied: as for inſtance, all hot ſandy lands ſhould have a cool manure; neats dung and ſwines dung are very proper for ſuch lands, as alſo marle and clay; but for cold lands, horſe dung, aſhes, or ſand, and other warm manures, are proper. And when theſe are applied, it ſhould be done in autumn, before the rains have ſoaked the ground, and rendered it too ſoft to cart on; and it ſhould be carefully ſpread, breaking all the clods as ſmall as poſſible, and early in the ſpring harrowed with buſhes, to let it down to the roots of the Graſs. When the manure is laid on at this ſeaſon, the rains in winter will waſh down the ſalts, ſo that the following ſpring the Graſs will receive the advantage of it.

There ſhould alſo be great care taken to deſtroy weeds in the Paſture, every ſpring and autumn; for where this is not practiſed, the weeds will ripen their ſeeds, which will ſpread over the ground, and thereby fill it with ſuch a crop of weeds as will ſoon over-bear the Graſs, and render it very weak, if not deſtroy it; and it will be very difficult to root them out, after they have got poſſeſſion; eſpecially Ragwort, Hawkweed, Dandelion, and ſuch other weeds as have down adhering to their ſeeds.

Theſe upland Paſtures ſeldom degenerate the Graſs which is ſown on them, if the land is tolerably good; whereas the low meadows, which are overflowed in winter, in a few years turn to a harſh ruſhy Graſs, but

* Hazard, in Bath papers, vol. 4. p. 244.

* Bath papers, 4. 287.

the upland will continue a fine ſweet Graſs for many years without renewing.

There is no part of huſbandry, of which the farmers are in general more ignorant, than that of the Paſture; moſt of them ſuppoſe, that when the old Paſture is ploughed up, it can never be brought to have a good ſward again; ſo their common method of managing their land after ploughing, and getting two or three crops of Corn is, to ſow with their crop of Barley, ſome Graſs-ſeeds as they call them; that is, either the red Clover, which they intend to ſtand two years after the Corn is taken off the ground, or Ray-graſs mixed with Trefoil; but as all theſe are at moſt but biennial plants, whoſe roots decay ſoon after their ſeeds are perfected, ſo the ground having no crop upon it, is again ploughed for Corn; and this is the conſtant round which the lands are employed in, by the better ſort of farmers: for I never have met with one of them, who had the leaſt notion of laying down their land to Graſs for any longer continuance; therefore the ſeeds which they uſually ſow, are the beſt adapted for this purpoſe.

But whatever may have been the practice, *I hope* to ſhow, that it is poſſible to lay down land, which has been in tillage, with Graſs, in ſuch manner as that the ſward ſhall be as good, if not better, than any natural Graſs, and of as long duration. But this is never to be expected, in the common method of ſowing a crop of Corn with the Graſs-ſeeds; for wherever this has been practiſed, if the Corn has ſucceeded well, the Graſs has been very poor and weak; ſo that if the land has not been very good, the Graſs has ſcarcely been worth ſtanding; for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected it ſhould be otherwiſe, for the ground cannot nouriſh two crops, and if there were no deficiency in the land, yet the Corn being the firſt, and moſt vigorous of growth, will keep the Graſs from making any conſiderable progreſs; ſo that the plants will be extremely weak and but very thin, many of them which came up in the ſpring being deſtroyed by the Corn; for wherever there are roots of Corn, it cannot be expected there ſhould be any Graſs. Therefore the Graſs muſt be thin, and, if the land is not in good heart to ſupply the Graſs with nouriſhment, that the roots may branch out after the Corn is gone, there cannot be any conſiderable crop of Clover; and as the roots are biennial, many of the ſtrongeſt plants will periſh ſoon after they are cut; and the weak plants, which had made but little progreſs before, will be the principal part of the crop for the ſucceeding year, which is many times not worth ſtanding.

Therefore, when ground is laid down for Graſs, there ſhould be no crop of any kind ſown with the ſeeds; and the land ſhould be well ploughed, and cleaned from weeds; otherwiſe the weeds will come up the firſt, and grow ſo ſtrong, as to overbear the Graſs, and if they are not pulled up, will entirely ſpoil it. The beſt ſeaſon to ſow the Graſs-ſeeds upon dry land is about the middle of auguſt, if there is an appearance of rain; for the ground being then warm, if there happen ſome good ſhowers of rain after the ſeed is ſown, the Graſs will ſoon make its appearance, and get ſufficient rooting in the ground before winter, ſo will not be in danger of having the roots turned out of the ground by the froſt, eſpecially if the ground is well rolled before the froſt comes on, which will preſs it down, and fix the earth cloſe to the roots. Where this has not been practiſed, the froſt has often looſened the ground ſo much, as to let in the air to the roots of the Graſs, and done it great damage; and this has been brought as an objection to the autumnal ſowing of Graſs; but it will be found to have no weight, if the above direction is practiſed; nor is there any hazard in ſowing the Graſs at this ſeaſon, but that of dry weather after the ſeeds are ſown; for if the Graſs comes up well, and the ground is well rolled in the middle or end of october, and repeated the beginning of march, the ſward will be cloſely joined at bottom, and a good crop of hay may be expected the ſame ſummer. In very open, expoſed, cold lands, it is proper to ſow the ſeeds earlier than is here mentioned, that the Graſs may have time to get good rooting, before the cold ſeaſon comes on to ſtop its growth; for in ſuch ſituations, vegetation is over early in the autumn, ſo the Graſs being weak, may be deſtroyed by froſt: but if the ſeeds are ſown in the beginning of auguſt, and a few ſhowers follow ſoon after to bring up the Graſs, it will ſucceed much better than any which is ſown in the ſpring, as I have ſeveral years experienced, on ſome places as much expoſed as moſt in England. But where the ground cannot be prepared for ſowing at that ſeaſon, it may be performed the middle or latter end of march, according to the ſeaſon's being early or late; for in backward ſprings and in cold land, I have often ſowed the Graſs in the middle of april with ſucceſs; but there is danger in ſowing late of dry weather, and eſpecially if the land is light and dry; for I have ſeen many times the whole ſurface of the ground removed by ſtrong winds at that ſeaſon, ſo that the ſeeds have been driven in heaps to one ſide of the field. Therefore whenever the ſeeds are ſown late in the ſpring, it will be proper to roll the ground well ſoon after the ſeeds are ſown, to ſettle the ſurface, and prevent its being removed.

The ſorts of ſeeds which are the beſt for this purpoſe, are the beſt ſort of upland Hay-ſeeds, taken from the cleaneſt Paſtures, where there are no bad weeds; if this ſeed is ſifted to clean it from rubbiſh, three, or at moſt four buſhels, will be ſufficient to ſow an acre of land. The other ſort is the Trifolium pratenſe album, which is commonly known by the names of White Dutch Clover, or White Honeyſuckle Graſs. Eight pounds of this ſeed will be enough for one acre of land. The Graſs-ſeed ſhould be ſown firſt, and then the Dutch Clover-ſeed may be afterward ſown; but they ſhould not be mixed together, becauſe the Clover-ſeeds being the heavieſt, will fall to the bottom, and conſequently the ground will be unequally ſown with them.

After the ſeeds are ſown, the ground ſhould be lightly harrowed to bury the ſeeds; but this ſhould be performed with a ſhort-toothed harrow, otherwiſe the ſeeds will be buried too deep. Two or three days after ſowing, if the ſurface of the ground is dry, it ſhould be rolled with a Barley roller to break the clods and ſmooth the ground, which will ſettle it, and prevent the ſeeds from being removed by the wind.

When the ſeeds are come up, if the land ſhould produce many weeds, theſe ſhould be drawn out before they grow ſo tall as to overbear the Graſs; for where this has been neglected, the weeds have taken ſuch poſſeſſion of the ground, as to keep down the Graſs and ſtarve it; and when theſe weeds have been ſuffered to remain until they have ſhed their ſeeds, the land has been ſo plentifully ſtocked with them, as entirely to deſtroy the Graſs; therefore it is one of the principal parts of huſbandry, never to ſuffer weeds to grow on the land.

If the ground is rolled two or three times at proper diſtances after the Graſs is up, it will preſs down the Graſs, and cauſe it to make a thicker bottom; for as the Dutch Clover will put out roots from every joint of the branches which are near the ground, ſo by preſſing down the ſtalks, the roots will mat ſo cloſely together, as to form a ſward ſo thick as to cover the whole ſurface of the ground, and form a green carpet, which will better reſiſt the drought. For if we do but examine the common Paſtures in ſummer (in moſt of which there are patches of this White Honeyſuckle Graſs growing naturally) we ſhall find theſe patches to be the only verdure remaining in the fields. And this the farmers in general acknowledge, is the ſweeteſt feed for all ſorts of cattle, yet never had any notion of propagating it by ſeeds till of late years. Nor has this been long practiſed in England; for till within a few years, that ſome curious perſons imported the ſeed from Brabant, where it had been long cultivated, there were not any of the ſeeds ſaved in England; though now there are ſeveral perſons who ſave the ſeeds here, which ſucceed full as well as any of the foreign ſeeds which are imported.

As this White Clover is an abiding plant, ſo it is certainly

certainly the very beſt ſort to ſow where Paſtures are laid down to remain; for as the Hay-ſeeds which are taken from the beſt Paſtures, will be compoſed of various ſorts of Graſs, ſome of which may be but annual and others biennial, ſo when thoſe go off, there will be many and large patches of ground left bare and naked, if there is not a ſufficient quantity of the White Clover to ſpread over and cover the land. Therefore a good ſward can never be expected where this is not ſown; for in moſt of the natural Paſtures, we find this plant makes no ſmall ſhare of the ſward; and it is equally good for wet and dry land, growing naturally upon gravel and clay in moſt parts of England; which is a plain indication how eaſily this plant may be cultivated to great advantage, in moſt ſorts of land throughout this kingdom.

The true cauſe why the land which is in tillage is not brought to a good turf again, in the uſual method of huſbandry is, from the farmers not diſtinguiſhing which Graſſes are annual, from thoſe which are perennial; if annual or biennial Graſſes are ſown, theſe will of courſe ſoon decay; ſo that unleſs where ſome of their ſeeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. This, together with the covetous method of laying down the ground with a crop of Corn, has occaſioned the general failure of increaſing the Paſture in many parts of England, where it is now much more valuable than any arable land.

After the ground has been ſown in the manner before directed, and brought to a good ſward, the way to preſerve it good is, by conſtantly rolling the ground with a heavy roller, every ſpring and autumn, as has been before directed. This piece of huſbandry is rarely practiſed by farmers, but thoſe who do, find their account in it, for it is of great benefit to the Graſs. Another thing ſhould alſo be carefully performed, which is, to cut up Docks, Dandelion, Knapweed, and all ſuch bad weeds, by their roots, every ſpring and autumn; this will increaſe the quantity of good Graſs, and preſerve the Paſtures in beauty.

Dreſſing theſe Paſtures every third year, is alſo a good piece of huſbandry, for otherwiſe it cannot be expected the ground ſhould continue to produce good crops. Beſides this, it will be proper to mow one ſeaſon, and feed the next; but where the ground is every year mown, it muſt be conſtantly dreſſed, as moſt of the Graſs grounds near London, otherwiſe the ground will be ſoon exhauſted.

Of late years there has been an emulation, eſpecially among gentlemen, to improve their Paſtures, by ſowing ſeveral ſorts of Graſs-ſeeds; and there have been ſome perſons of little ſkill in theſe matters, who have impoſed on many ignorant people, by ſelling them ſeeds of ſome foreign Graſs, recommending them for ſome particular quality, but when tried have proved of little worth, whereby they have loſt a ſeaſon or two, and have had their work to begin again. Therefore I would adviſe every perſon, not to truſt too much upon the faith of ſuch practitioners, who, upon ſlight experiments, have ventured to recommend without judgment; for of all the ſorts of Graſs-ſeeds which have been brought from America (of which I have, at various times, ſown more than a hundred different ſpecies) I have found none equal to the common Poa Graſs, which grows naturally in England, either for duration or verdure; therefore that, and about ſix or ſeven other ſorts, are the beſt worth cultivating; but the trouble of collecting theſe in quantity is ſo great, as to deter moſt people from attempting it; and in the purchaſing of Hay-ſeeds, there is generally more ſeeds of weeds than Graſs, which will fill the ground; therefore for ſome years paſt, I have recommended and ſown only the White Dutch Clover-ſeeds, and have waited for the natural Graſs coming up amongſt it, and have generally ſucceeded better this way than by ſowing Hay-ſeed with it; for if the Paſture is duly weeded, rolled, and dreſſed, all bad weeds may be deſtroyed, and a fine durable turf obtained: whereas the Burnet, and many other plants, which have been extolled as a good winter food, being of ſhort duration, are very improper for improving land; nor are there two better plants yet known for the purpoſe of fodder, than the Lucern and Saintfoin; for where theſe are properly ſown upon right ſoils and duly cultivated, they will produce a much greater quantity of food, than can be procured from the ſame quantity of land, ſown with any other abiding plant: therefore I wiſh thoſe who are curious to have much fodder for their cattle, to apply themſelves to the culture of theſe, and not engage in uncertain experiments.

[The following directions for laying down land to Graſs are given by Mr. Stillingfleet. Plough the land in march as deep as the nature of the ſoil will admit. Harrow when the weeds are about flowering, namely, ſome time in may, or ſooner, if it be a forward ſpring. Plough about ten days after harrowing. Harrow when the weeds are come up again. If any dung or compoſt be prepared for the land, let it be laid on. Plough at this time, and plough it in a moderate depth immediately, ſo that the teeth of the harrow after rolling may reach it. Roll the land down every day as it is ploughed with a light roller, and obſerve not to ſpread the dung long before it is ploughed in. Harrow well when the weeds come up that are produced by the dung, ſo as to bring the dung up and mix it with the ſoil; obſerving not to harrow more at once than can be ploughed in one day. Plough it up after the harrows the ſame depth as before, and follow the plough with a roller. The land will now be under the proper preparation for the ſeeds, which may be ſown after the firſt ſoaking rain from the end of auguſt to the end of ſeptember, in the following manner. Plough the land about the ſame depth as before. Harrow it once in a place, and ſow the ſeeds after the harrow. Then with a hurdle buſhed with black-thorn-buſhes harrow the ſeeds in. When the plants appear, roll the land with a light roller, and not before, except the weather prove very dry, in which caſe it will be neceſſary to roll it with a very light roller after the buſh-harrow. A light dreſſing of good manure laid on with the firſt froſt, will be of great uſe in preſerving the Graſs the firſt ſeaſon, and encouraging its growth afterwards. And a light roller uſed after every froſt will be of great ſervice the firſt winter.

In Yorkſhire they have three ways of ſowing Graſs-ſeeds: 1ſt, in auguſt; 2dly with Barley, which is moſt uſed; 3dly, upon Wheat, in march. The firſt way is the beſt; and the ſecond is better than the laſt.

The quantity ſown is ten buſhels to the acre, four pounds of hop-trefoil (Medicago lupulina, Black Nonefuch) or White Clover, and ſome add two pounds of Ray-graſs.

After the crop is cut, ſuffer no cattle to enter, till next hay-harveſt, when the Graſs may be either cut or fed. But there is danger from the cattle in the laſt way. The farmers generally mow the firſt crop for the ſake of ſeeds, becauſe that affords more than the ſucceeding ones. If ſown with Barley, roll as ſoon as the Barley is off the ground. Lay on dung after the firſt crop of Graſs is mowed.

The following is a liſt of Herbs of Paſture, or of ſuch plants as are commonly found growing among Graſs, whether uſeful or injurious, with obſervations; diſpoſed alphabetically according to their botanical names: with references from their common Engliſh ones.

Achillea Millefolium. *Common Yarrow* or *Milfoil.* Common on all ſoils. Perennial. Flowering from june to auguſt. The white and purple flowers differ only in colour. The roots creep prodigiouſly, eſpecially where rubbiſh or dung has been laid. It has been generally execrated as a weed, but ſheep and ſometimes cattle will eat it; and Dr. Anderſon has recommended it for cultivation on poor lands. In a dry ſummer, animals eat this and many other plants in the following liſt, which they leave untouched when there is plenty of Graſs. Perhaps ſome of them act medicinally, and ought not therefore to be rejected in mowing and paſture grounds.—Milfoil is reputed an excellent vulnerary and ſtyptic, good in hæmorrhages and dyſenteries, and the ſcab in ſheep.

Achillea Ptarmica. *Sneezewort.* Chiefly in moiſt meadows, or among buſhes on the ſides of paſtures, or

on

on the banks of ditches or in moiſt woods, and ſometimes on the balks of corn fields. It is hardly common enough among Graſs to be conſidered as making a part of Paſture herbage. It is perennial and creeps. Flowers in july and auguſt. In ſpring the young ſhoots are put into ſalads, to correct their coldneſs. The roots being hot and biting are uſed in the tooth-ach; whence it has the name of Baſtard Pellitory. From the form of the leaf it is called Gooſe-tongue. The leaves dried and powdered provoke ſneezing, whence its common name. With double flowers it is common in old gardens, under the name of double Ptarmica or Batchelor's buttons. The flowers are white.

ADDER'S TONGUE. See *Ophioglossum*.

AGRIMONIA EUPATORIA. *Common Agrimony*. Chiefly on the borders of Paſtures, but ſometimes in the body of them. Perennial. Flowers yellow, appearing in june and july. Dyes yellow. Dreſſes leather. Good in the jaundice and all obſtructions.

AJUGA REPTANS. *Common Bugle, Middle Conſound, Sicklewort*, or *Herb Carpenter*. Frequent in moiſt meadows and woods. Perennial, increaſing greatly by the ſide ſhoots. Flowers blue; in may and june. Vulnerary, cooling and aſtringent.

ALCHEMILLA VULGARIS. *Common Ladies Mantle*, or *Bear's-foot*. In high paſtures, not very common in the ſouth of England; it ſpreads greatly in the ſoil it likes. Vulnerary and aſtringent. Horſes, ſheep and goats eat it; but kine are not fond of it. Flowers ſmall and herbaceous, appearing from june to auguſt.

ALLIUM VINEALE. *Crow Garlick*. Frequent, and giving butter an inſufferably ſtrong taſte. Perennial, bulbous, flowering in june.

ALLIUM URSINUM. *Wild Garlick* or *Ramſons*. Woods and hedges; ſometimes in meadows, giving alſo a ſtrong flavour to milk and butter. Flowering in may.

ALSINE MEDIA. *Common Chickweed*. Wild almoſt every where: but not ſo common in paſtures as in gardens and arable land. Annual.

ANEMONE NEMOROSA. *Wood Anemone*. Moſt common in woods and hedges, but ſometimes in paſtures. Perennial: flowering from march to may. Acrid: according to Linneus, cattle (or ſheep) brought from open to woody paſtures, and eating this plant, are affected with the bloody flux, or make bloody urine.

ANEMONE PULSATILLA. *Paſque-flower*. Only on high paſtures or downs, and not common. Flowers purple and handſome. Acrid, but ſeems not to be eaten by ſheep.

ANONIS. See *Ononis*.

ANTHEMIS NOBILIS. *Common* or *Sweet Chamomile*. Perennial, trailing; on dry commons; flowering in july and auguſt. The flowers are generally known as an excellent medicine, and the ſingle wild flowers are far ſuperior to the double ones which are found in the ſhops.

ANTHYLLIS VULNERARIA. *Common Ladies-finger*, or *Kidney-Vetch*. In dry paſtures, chiefly in a calcareous ſoil. It is perennial; and in its natural ſtate dry and rather aſtringent. It remains to be ſeen, whether it would prove ſucculent and productive enough in a good ſoil to render it worth cultivation. Mr. Young ſays, it abounds in the beſt meadows of the Pyrenees: but it will probably never rival *Lotus Corniculata*, with which it has been confounded. The flowers are yellow, and the whole plant has a whitiſh appearance.

ANTIRRHINUM LINARIA. *Common Toadflax, Wild Flax, Flax-weed, Butter and Eggs*. Chiefly in barren paſtures. Perennial; creeping very much. It flowers from june to auguſt. Abounds in an acrid oil. Recommended in the dropſy, but moſt approved as a cataplaſm, with lard, in the piles. The juice, with milk, is a poiſon to flies. Flowers pale yellow, with an orange palate.

APHANES ARVENSIS. *Parſley-piert*. A little annual plant, with inconſiderable herbaceous flowers, growing in dry paſtures and on fallow fields, flowering from may to auguſt.

ARCHANGEL. See *Lamium*.

ARSMART. See *Polygonum*.

ASTRAGALUS GLYCYPHYLLUS. *Wild Liquorice* or *Liquorice Vetch*. Paſtures, eſpecially in a calcareous ſoil, but more common in hedges. A large plant, ſweet with a mixture of bitterneſs: on the latter account ſeemingly leſs agreeable to cattle than moſt of the leguminous plants. Flowers greeniſh yellow, appearing in june and july. Dr. Anderſon treats largely of *Lotus corniculata* or Bird's-foot Trefoil under this name.

ASTRAGALUS HYPOGLOTTIS. *Purple mountain Milk-Vetch*. Aſtrag. arenarius of Britiſh writers. A ſmall perennial plant, with elegant purple flowers, large for the ſize of the plant, found in ſandy and chalky paſtures, flowering from may to july.

BASIL. See *Clinopodium*.

BEDSTRAW. See *Galium*.

BELL-FLOWER. See *Campanula*.

BELLIS PERENNIS. *Perennial* or *common Daiſy*. In Yorkſhire *Dog-Daiſies* and *Bairn-worts*. A well known weed in moſt paſtures, that ſeems not to be eaten by any quadrupeds.

BETONICA OFFICINALIS. *Wood Betony*. The growth of woods, as the Engliſh name implies; but found alſo in paſtures, chiefly ſuch as are overrun with buſhes. Mr. Marſhall ſays it is a common article of herbage in the graſs-lands of Yorkſhire, in every ſoil and ſituation from the marſh to the mountains. In other parts of the iſland it is a certain indication of the land having been in wood.

BISTORTA. See *Polygonum*.

BLUE-BOTTLE. See *Centaurea*.

BRAKES. See *Pteris*.

BUGLE and BUGULA. See *Ajuga*.

BUNIUM BULBOCASTANUM. *Earth-nut, Pig-nut, Kipper-nut, Hawk-nut, Jur-nut* or *Yer-nut, Earth Cheſtnut, Ground-nut*. On heaths, commons and dry paſtures, chiefly among buſhes, in a gravelly or ſandy ſoil; flowering in may and june. The tuberous root is coveted by ſwine, and ſometimes eaten by children.

BURNET. See *Poterium* and *Sanguiſorba*.

BUTTER-BUR. See *Tuſſilago*.

BUTTER-CUPS. See *Ranunculus*.

CALTHA PALUSTRIS. *Marſh Marygold. Meadow-Boot*. Wet meadows, and by the ſides of wet ditches and ſtreams; adorning them in march and april, with its large bright yellow flowers. Cattle do not eat it, unleſs compelled by extreme hunger, and Boerhaave affirms that it is dangerous to them.

CAMMOCK. See *Ononis*.

CAMOMILE. See *Anthemis*.

CAMPANULA ROTUNDIFOLIA. *Round-leaved* or *common Bell-flower*. Common on heaths and other waſtes, in dry hilly ſituations. Flowers blue, varying to white, appearing from june to ſeptember. The root-leaves, which alone are round, are ſeldom ſeen, being hid in the graſs, and dropping off as the flower-ſtem advances. This plant, in the body of a paſture, indicates dryneſs, approaching to barrenneſs.

Campanula Rapunculus, or Rampions, is found in England, but rarely.

CAMPANULA GLOMERATA. *Small* or *cluſtered Bell-flower*, or *Little Canterbury Bells*, grows in hilly dry paſtures, particularly in a calcareous ſoil, flowering from june to ſeptember. Corolla blue, varying to purple and white.

CAMPION. See *Cucubalus* and *Lychnis*.

CARAWAYS. See *Carum*.

CARDAMINE PRATENSIS. *Common Ladies Smock, Cuckow-flower*: ſaid to be called *Canterbury Bells* in Norfolk; but ſurely this muſt be a miſtake, the flowers not having the moſt diſtant reſemblance to the bell ſhape. General in moiſt meadows, and by the ſides of ditches and ſtreams, flowering with the firſt appearance of the cuckow. Warm and antiſcorbutic. Recommended in hyſteric and epileptic caſes. Sheep eat it, at leaſt when firſt turned into a meadow or marſh; and it is probably wholeſome for them.

CARDUUS. *Thiſtle*. Moſt of the Thiſtles infeſt arable land; and being biennial, except the Way-Thiſtle, (for which ſee *Serratula*) might eaſily be extirpated, by not ſuffering them to ſeed. Some of this genus however are paſture weeds: as—

CARDUUS PALUSTRIS. *Marſh Thiſtle*, in Yorkſhire *Red Thiſtle*. In marſhes, wet meadows, boggy woods, and wet parts of heaths and commons. Five or ſix feet, and in woods ten or twelve feet high.

CARDUUS PRATENSIS. *Huds. Meadow Thiſtle*. In wet meadows.

CARDUUS ERIOPHORUS. *Woolly-headed Thiſtle*. The handſomeſt of all our Thiſtles. Eaſily known by its large woolly heads. In dry paſtures, by road ſides and in waſte places.

CARDUUS ACAULIS. *Dwarf Carline Thiſtle*. One of the moſt pernicious weeds in dry paſtures; ſpreading cloſe to the ground a foot in diameter, ſuffering no plant to grow near it, and pricking the noſes of the cattle. It flowers in july, and is ſaid to be perennial.

There are other ſpecies of Thiſtle found in paſtures, but they are rare and not noxious.

CARDUUS ARVENSIS. See *Serratula*.

——— STELLATUS. See *Centaurea*.

CAREX. *Sedge*. Species very numerous. Reſemble Graſſes, but are of a much harſher texture, the ſtem commonly three-cornered, and the leaves toothed like a ſaw along the edge. They grow moſtly in wet ſwampy grounds, or by the ſides of ditches and ſtreams: ſome however affect hilly paſtures and heaths, and may be diſtinguiſhed from the Graſſes, not only by their fructification, but by their blueneſs. In the ſens they are mown for a coarſe fodder. In meadows, draining and coal-aſhes will deſtroy them.

CARLINA VULGARIS. *Common Carline-Thiſtle*. Biennial; in dry paſtures. Indicates barrenneſs. Said to be a good remedy in hyſterical caſes. It is about a foot high, and flowers from june to ſeptember.

CARROT. See *Daucus*.

CARUM CARUI. *Common Caraway*. In rich meadows, but not common. Biennial. Flowering in may and june.

CATMINT. See *Nepeta*.

CENTAUREA NIGRA. *Black Centaury* or *Knap-weed*, variouſly pronounced *Knop-weed*, *Knob-weed*; alſo *Horſe-knops*, from *Knob* or *Nob*, a head. In Scotland *Horſe-Knot*. Other provincial names are *Cock-heads*, *Hard-heads*, *Hard-irons*, *Bulward* and *Matfellon*. It is a bad perennial weed, harſh and ſtubborn, not eaten either in graſs or in hay, increaſing much by the root, and not eaſily extirpated.

A larger ſort, called *Great Knapweed* or *Knobweed*, in Yorkſhire *Great Horſe-knobs*, *Centaurea Scabioſa*, occurs in meadows, but more commonly in arable fields and their borders, and by road ſides. It is perennial, and flowers in july and auguſt.

CENTAUREA CALCITRAPA. *Star-thiſtle*. In dry barren paſtures, and by way ſides. Annual, very ſpreading, prickly. Flowers red, appearing in auguſt. Very bitter, and ſaid to be uſed by brewers, when Hops are dear.

CERASTIUM. *Mouſe-ear*. Several ſpecies are found among Graſs, but they are ſmall annual plants, reſembling Chick-weed, of little value or detriment. *C. arvenſe* is found not only in arable fields, as the name implies, but in ſandy paſtures.

CHÆROPHYLLUM SYLVESTRE. *Wild Cicely*, *Cow-weed*, *Common Cow-Parſley*. Very common in paſtures, orchards and under hedges, flowering in may. Not unlike Hemlock, confounded with it by the country people, under the name of *Homlockes* when green, and *Keckſies* or *Kexes* when dry; but it is a ſmaller plant than Hemlock, of a paler green, and the ſtalk is not ſpotted. Rabbets and cows are fond of it when young. Linneus ſays that it indicates a luxuriant ſoil, and that the flowers may be uſed to dye wool both green and yellow.

CHÆROPHYLLUM TEMULUM. *Rough Cow-Parſley*, is diſtinguiſhed from the preceding by the roughneſs, deep purple colour and ſwelled joints of the ſtem, it alſo flowers a month or ſix weeks later, and is more confined to hedges. The ſtem being generally ſpotted with purple, this is more frequently miſtaken for Hemlock than the other.

CHEESE-RENNING. See *Galium*.

CHICKWEED. See *Alſine*.

CHLORA PERFOLIATA. *Yellow Centaury*, or *Perfoliate Yellow-wort*. *Gentiana perfoliata*. An annual plant, in paſtures, on chalky and limeſtone ſoils; flowering from june through the autumn. The plant glaucous, with gold-coloured flowers. Haller affirms, that it is more bitter than purple Centaury, *Gentiana Centaurium*.

CHRYSANTHEMUM LEUCANTHEMUM. *Common Ox-eye*, *Great Daiſy*, *Moon-flower*, *Maudlin-wort*. Very common in dry paſtures, flowering from may to july. Flowers large, the diſk yellow and the ray white. Perennial, ſomewhat creeping, and increaſing much by ſeed.

CICHORIUM INTYBUS. *Wild Succory*, *Cichory* or *Chicory*. Frequent among graſs on the borders of fields, flowering from july to ſeptember. In its wild ſtate hard, dry and juiceleſs, but very ſucculent as improved for cultivation.

CINQUEFOIL. See *Potentilla*.

CISTUS HELIANTHEMUM. *Dwarf Ciſtus* or *Little Sun-flower*. Dry paſtures, generally in calcareous ſoils. Perennial. Flowering from june to auguſt. It is a trailing plant, with handſome yellow flowers.

CLARY. See *Salvia*.

CLINOPODIUM VULGARE. *Wild Baſil*. In chalk and limeſtone paſtures, but more frequently in the hedges. Perennial. June. Flowers purple. Smell ſlightly aromatic, not unpleaſant.

CLOVER. See *Trifolium*.

COCK'S-COMB. See *Rhinanthus*.

COLCHICUM AUTUMNALE. *Common Meadow Saffron*, *Naked Ladies*. Orchards and meadows. Root bulbous, poiſonous or at leaſt highly acrimonious. An infuſion in vinegar, made into a ſyrup with ſugar or honey, is a uſeful pectoral and diuretic. It is leſs nauſeous than Squill, though more ſedative. No cattle eat this plant. The flowers, which reſemble thoſe of the purple Crocus, appear in autumn, and the leaves in ſpring.

COLT'S-FOOT. See *Tuſſilago*.

CONIUM MACULATUM. *Common Hemlock*. Rather by hedge and way ſides, among rubbiſh, and on dung-hills, than in paſtures. A biennial plant, known by its large ſpotted ſtalk, from four to ſix feet high, by the dark ſhining green colour of its large bottom leaves, and particularly by their diſagreeable ſmell when bruiſed. In its dry ſtate, it is the principal of the *Keckſies*.

This plant is poiſonous when imprudently uſed; but one of our beſt medicines in ſmall doſes, in ulcers, tumours, &c. From fifteen to twenty grains of the powdered leaves may be taken twice or thrice a day in chronic rheumatiſms.

CONYZA SQUARROSA. *Great Fleabane* or *Ploughman's Spikenard*. A biennial plant from two to three feet in height; found in dry hilly paſtures, by hedge-ſides and in woods; flowering from july to october.

CORN-SALAD. See *Valeriana*.

COW-PARSNEP. See *Heracleum*.

COW-WEED. See *Chærophyllum*.

COW-WHEAT. See *Melampyrum*.

COWSLIPS. See *Primula*.

CREPIS. Several ſpecies of this genus occur in paſtures, chiefly ſuch as are dry; they have yellow flowers, and are confounded with the Hawkweeds, &c. under the common name of *Gelds* or *Goulds* by the country people. They have nearly the ſame qualities with *Dandelion*, and rather do good than harm.

CROWFOOT. See *Ranunculus*.

CUCKOW-FLOWER. See *Cardamine*.

CUCUBALUS BEHEN. *Bladder Campion*, *Spattling Poppy*, *White Corn Campion*, *White Bottle*. In dry paſtures, but more common in corn fields. Perennial, ſmooth, flowers white, appearing in june, july and auguſt. Known by its inflated calyx, commonly veined like a net with green or brownish purple.

CUDWEED. See *Gnaphalium*.

DAISY. See *Bellis*.

DANDELION. See *Leontodon*.

DAUCUS CAROTA. *Wild Carrot*, *Bird's neſt*. *Bee's-neſt*. Common in paſtures, on balks and headlands. Biennial. June to auguſt. Seeds a powerful diuretic: an infuſion of them gives relief in the ſtone and gravel.

DEVIL'S-BIT. See *Scabioſa*.

DIANTHUS ARMERIA. *Deptford Pink.* A pretty little plant among graſs, but chiefly in buſhy places and woods.

DIANTHUS PROLIFER. *Proliferous Pink.* In ſandy paſtures, but not common.

DIANTHUS DELTOIDES. *Maiden Pink.* Paſtures and heaths, on a light ſoil, not uncommon.

DIGITALIS PURPUREA. *Purple Fox-glove.* Sandy and gravelly ſoils, in gravel-pits, in and about woods, and in waſte places, ſeldom in the body of a paſture.

DOCK. See *Rumex.*

DROPWORT. See *Spiræa.*

ELECAMPANE. See *Inula.*

ERICA VULGARIS. *Common Heath.* General on dry paſtures, called heaths from the prevalence of this ſhrub. Extirpated by paring and burning.

ERIGERON ACRE. *Blue Erigeron* or *Flea-bane.* In dry ſandy and chalky paſtures, and on walls, but not very common. July to ſeptember.

ERIOPHORUM VAGINATUM. *Mountain* or *ſingle-ſpiked Cotton-graſs.*—E. anguſtifolium. *Narrow-leaved Cotton-graſs.*—*Hare's-tail Raſh. Moſs-crops.* Moors and boggy ground, which are often white with theſe plants in june and july; they flower in april and may. Early in ſpring, before the graſſes are ſufficiently grown, ſheep crop the leaves.

EUPHRASIA OFFICINALIS. *Common Eye-bright.* A ſmall annual plant, common on heaths and commons. In paſtures indicating ſterility. It flowers from july to ſeptember.

FERN. See *Pteris.*

FICARIA. See *Ranunculus.*

FLAG. See *Iris.*

FLEABANE. See *Inula.*

FOX-GLOVE. See *Digitalis.*

GALANTHUS NIVALIS. *Snow-drop. Fair Maids of February.* This, with ſeveral other bulbous plants, is often found in orchards, and paſtures that may once have been orchards.

GALIUM. Several ſpecies of Galium or *Bedſtraw* occur in paſtures.

G. paluſtre. *White Ladies Bedſtraw.* In moiſt meadows, and on the banks of rivers and ditches; flowering in july.

G. uliginoſum. *Marſh Ladies Bedſtraw.* On wet heaths, bogs, low meadows, and by river ſides; flowering in july and auguſt.

G. verum. *Yellow Ladies Bedſtraw. Cheeſe-renning.* Common in paſtures, and by the ſides of fields and roads in a dry ſoil; flowering from june to ſeptember, flouriſhing in the moſt unremitting drought. Flowers yellow; thoſe of the two former white. Suppoſed to curdle milk. The flowering ſtems dye a good yellow. The roots dye a brighter red than Madder.

G. erectum. *Upright Ladies Bedſtraw.* Meadows and moiſt paſtures. Flowers white.

G. Mollugo. *Great Ladies Bedſtraw.* Common in hedges and among buſhes, flowering from june to auguſt. Flowers white.

G. Aparine. *Cleavers* or *Gooſe-graſs*, keeps to hedges and cultivated grounds.

GARLICK. See *Allium.*

GENTIANA PNEUMONANTHE. *Marſh Gentian* or *Calathian Violet.* In wet meadows and marſhes, and the boggy parts of heaths, chiefly in the north of England.

G. Centaurium. *Leſſer Centaury.* Dry paſtures. A ſmall annual plant with purple flowers, appearing from june to auguſt. Extremely bitter, and the baſis of the Portland powder. A tincture of it is a good medicine to weak ſtomachs. A decoction of the whole plant deſtroys lice, and cures the itch.

G. Amarella and campeſtris. *Autumnal* and *Field Gentian.* Both ſmall annual plants in dry paſtures, with purple flowers.

GERANIUM CICUTARIUM. *Hemlock Crane's-bill.* In ſandy paſtures. Annual.

G. moſchatum. *Muſk Crane's-bill.* Dry paſtures.

G. phæum. *Spotted Crane's-bill.* In high paſtures.

G. ſylvaticum. *Wood Crane's-bill.* High paſtures, among buſhes and in woods.

G. pratenſe. *Meadow Crane's-bill.* In moiſt meadows.

G. pyrenaicum, molle, rotundifolium, columbinum, diſſectum. Moſtly in dry paſtures. Annual.

GNAPHALIUM or *Cudweed*; ſeveral ſorts in dry paſtures; G. germanicum moſt common. G. uliginoſum, where water has ſtood in winter.

GOAT'S-BEARD. See *Tragopegon.*

HAREBELLS. See *Hyacinthus.*

HAWKWEED. See *Hieracium.*

HEATH. See *Erica.*

HEDYSARUM ONOBRYCHIS. *Saint-foin.* On hilly paſtures and open downs, particularly in a calcareous ſoil, flowering in june and july.

HEMLOCK. See *Conium.*

HERACLEUM SPHONDYLIUM. *Common Cow-Parſnep, Meadow Parſnep, Madnep*; in Norfolk *Hogweed*, by which name Knot-graſs (Polygonum aviculare) is known in ſome other counties. Paſtures, orchards, hedges, woods, in moiſt and fertile ſoils. Biennial. Flowering from may to july. Swine and rabbets are fond of the leaves; kine, goats and ſheep will alſo eat them. Kine are even ſaid to be very fond of this plant when cut young.

HIERACIUM. *Hawkweed.* Several plants which have compound yellow flowers, but not of this genus, are confounded under the name of Hawkweed. One ſpecies, *H. Pilioſella* or *Mouſe-ear*, is very common in dry paſtures, flowering from may to ſeptember. It has a perennial creeping root; the barren ſtalks or runners are procumbent, and the flowering ſtalks are from four to ſeven inches high, having one flower at top of a pale yellow or brimſtone colour; the ſtalk and leaves have long hairs.

H. paludoſum, *Marſh Hawkweed*, occurs in wet meadows, but is not common in England. See *Crepis* and *Hypochæris.*

HIPPOCREPIS COMOSA. *Tufted Horſe-ſhoe Vetch.* On chalk downs, flowering from april to july. It is a perennial, trailing, ſmooth, elegant, with abundance of yellow pea flowers, and remarkable pods, the parts of which are curved like a horſe-ſhoe.

HYACINTHUS NON SCRIPTUS. *Common Hyacinth* or *Harebells.* Common in woods, coppices, and hedge-rows of paſtures, adorning them with its ſpikes of pendant blue flowers in the ſpring. The freſh roots are poiſonous.

HYOSERIS MINIMA. *Small Swine's Succory.* Paſtures in a ſandy ſoil. Annual, not very common.

HYPERICUM PERFORATUM. *Common* or *perforated St. John's-wort.* Woods, thickets, banks, and hedges, but not in the body of paſtures, except ſuch as are buſhy. Perennial, two feet high, with handſome yellow flowers, appearing from july to ſeptember. Known by the ſmall black glands ſprinkled over the plant, and the numerous holes which appear on the leaves when held up to the light. The flowers are uſed by the common people to make an ointment, but no regard is paid to it by the faculty.

Other ſpecies are found in hedges: as—

H. Androſæmum, or *Tutſan St. John's-wort.* H. hirſutum or *hairy St. John's-wort.* H. montanum, or *Mountain St. John's-wort*: and H. quadrangulare, *Square-ſtalked St. John's-wort* or *St. Peter's-wort.*

Two ſmaller ſorts are found in dry paſtures and heaths, but chiefly among buſhes.

H. humifuſum, *Trailing St. John's-wort*; and H. pulchrum, *Upright St. John's-wort.*

HYPOCHÆRIS RADICATA. *Long-rooted Hypochæris* or *Hawkweed.* Common in dry paſtures, on banks and heaths, and very conſpicuous with its yellow flowers in the early part of ſummer. Stems from one to two feet high; but in barren ſoils not more than five or ſix inches. The length of the root, which is the thickneſs of the little finger, diſtinguiſhes this plant from *Leontodon autumnale* and other plants which bear ſome reſemblance to it in the flowers.

H. glabra and maculata are found in dry paſtures, but not common.

JASIONE MONTANA. *Hairy Sheep's Scabious, Scabious Sheep's-bit. Rampions with ſcabious like heads.* Common on dry ſandy grounds, heaths and hilly paſtures, flowering from june to auguſt. Annual. Flowers blue

blue in a head. The whole plant is milky, and ſometimes eaten by ſheep.

INULA HELENIUM. *Elecampane.* One of the largeſt of our herbaceous plants, being from three to five feet high, with large yellow flowers. In moiſt meadows and hedges. The root is a good pectoral. A decoction of it cures ſheep of the ſcab, hence its name *Scab-wort*; in ſome counties it is called *Horſe-heal*, probably from its reputed virtues in curing the cutaneous diſeaſes of horſes.

INULA DYSENTERICA. *Common* or *middle Fleabane.* Moiſt meadows, watery places, by the ſides of ditches and ſtreams, flowering from july to october, often overrunning large tracts of land, and generally left untouched by animals. Stem from one to two feet high. Flowers yellow rayed. Linneus named it *dyſenterica*, from the Ruſſian ſoldiers having been cured of the dyſentery by it; the ſmoke of it is ſaid to chaſe away fleas and other inſects, hence our Engliſh name.

Inula uliginoſa. *Small dwarf* or *marſh Fleabane.* Common where water has ſtagnated in winter, by road ſides, on the banks of ponds, &c. in a ſtiffiſh ſoil. This has the ſame qualities with the preceding, and is given to horſes for the botts. Both ſorts flower from auguſt to october.

IRIS PSEUDACORUS. *Common yellow* or *water Iris*, or *Flower-de-luce, Yellow Flag, Water Flag, Skeggs* or *Lugs.* Marſhy meadows and fens, by the ſides of ſtreams, pools and ditches; flowering in june and july.

Iris fœtidiſſima. *Stinking Iris, Gladwin* or *Gladdon*, in hedges only.

JUNCUS. *Ruſh. Seaves* in Yorkſhire. There are ſeveral ſorts of Ruſhes in paſtures. The moſt common are Juncus conglomeratus or *round-headed Ruſh*; J. effuſus or *common ſoft Ruſh*; and J. tenax or *common hard Ruſh.* In wet meadows and marſhes; always indicating a ſoil that holds wet. They are uſed, particularly the ſecond, for making ſmall baſkets and toys, and the wicks for watch-lights. For the method of deſtroying them in paſtures, ſee *Juncus effuſus.*

Other ſorts are common on boggy grounds, and J. campeſtris on dry paſtures and heaths, but theſe are all ſmaller plants, and are not found on good ground.

KIDNEY-VETCH. See *Anthyllis.*

KNAPWEED. See *Centaurea.*

KNOT-GRASS. See *Polygonum.*

LADIES BEDSTRAW. See *Galium.*

——— FINGER. See *Anthyllis.*

——— MANTLE. See *Alchemilla.*

——— SMOCK. See *Cardamine.*

LAMB'S LETTUCE. See *Valeriana.*

LAMIUM ALBUM. *White Archangel* or *Dead-Nettle:* and purpureum or *purple Archangel* or *Dead-Nettle* are ſometimes found in ſoul meadows, but more commonly in hedges, and by way ſides.

LAPATHUM. See *Rumex.*

LATHYRUS NISSOLIA. *Crimſon Graſs-Vetch.* In mowing graſs; the leaves ſo like thoſe of Graſs as to be overlooked, till it ſhows the beautiful crimſon pea flowers. It grows alſo among buſhes and in woods.

LATHYRUS PRATENSIS. *Common yellow* or *Meadow Vetchling, Tare everlaſting.* Meadows and paſtures, woods, thickets and hedges; flowering from june to auguſt. Perennial, creeping. Flowers yellow, of the pea ſhape, ſeveral together. It ſeems worth cultivating with Graſs ſeeds.

Other ſpecies are found in hedges and woods, but not very common.

LEONTODON TARAXACUM. *Common Dandelion.* Common in meadows every where; flowering from april to ſeptember, and later in mild weather. Early in the ſpring the leaves are no bad ingredient in ſalads. The French eat them blanched, and alſo the roots. Its diuretic effects have given it a vulgar name well known. The expreſſed juice has been given to the quantity of four ounces, three or four times a day, in obſtructions of the bowels. Swine devour the plant greedily; Linneus ſays that ſheep and kine are not fond of it, and that horſes refuſe it. The Gloceſterſhire dairymen, according to Mr. Marſhall, obſerve, that cows have an averſion to the bitter graſſes, as they call Dandelion and the Hawkweeds; but that ſheep are particularly partial to them, eating the very flowers.

LEPIDIUM LATIFOLIUM. *Broad-leaved Pepperwort* or *Dittander. Poor man's Pepper.* Among graſs, chiefly in ſalt marſhes, but not very common. It flowers in july. Perennial. Acrid, antiſcorbutic, formerly uſed inſtead of Horſe-radiſh. The young leaves ſometimes eaten in ſalads.

LETTUCE, LAMB'S. See *Valeriana.*

LINUM CATHARTICUM. *Purging Flax.*

LOTUS CORNICULATA. *Common Bird's-foot Trefoil, ſmall cocked Trefoil, Bird's-foot Clover* or *Clover, Cheeſecake-graſs, Butter-jags, Crow-toes.* Recommended for cultivation by Ellis, under the name of *Ladies Finger*; and by Anderſon, under that of *Aſtragalus glycyphyllos* or *Milkwort.* See *Aſtragalus.*

Bird's-foot Trefoil is common in meadows, paſtures, heaths, by road ſides, in hedges, among buſhes, and in woods; flowering from june to auguſt. There is a a very full deſcription and hiſtory of it under its proper head.

LUCERN. See *Medicago.*

LYCHNIS FLOS CUCULI. *Red-flowered Meadow Lychnis, Meadow Pink, Wild Williams, Cuckow Flower, Ragged Robin, Crow-flower, feathered wild Campion, marſh Gilliflower, Cuckow Gilliflower, Meadow Campion, Ragged Robin.* Moiſt meadows, flowering in may and june. Perennial. Flowers pink or purpliſh red and jagged. None of our domeſtic quadrupeds ſeem fond of it.

LYCHNIS VESPERTINA. *L. dioica* of Linneus. *White-flowered Lychnis, Wild White Campion.* Fallow fields, by hedges, ditches and highways, among buſhes, and not uncommonly in paſtures. I have not ſeen the *Red Wild Campion* or *Lychnis diurna* in the body of paſtures, but by moiſt ſhady ditches and hedges, and ſometimes in woods. The White Campion prefers dry ſoils.

LYSIMACHIA VULGARIS. *Common Looſe-ſtrife.* In marſhy meadows, and on the banks of ſtreams; flowering from the end of june to ſeptember. Perennial, with yellow flowers in a large panicle.

LYSIMACHIA NUMMULARIA. *Creeping Looſe-ſtrife, Moneywort, Herb Twopence* and *Twopenny Graſs*, from the round ſhape of the leaves. Moiſt meadows, on the ſides of ditches, and under wet hedges; flowering in june and july. Perennial, with trailing ſtalks, and large yellow flowers. According to Linneus, eaten by kine and ſheep, not much reliſhed by goats, and refuſed by horſes. An infuſion of the plant in oil is ſaid to deſtroy weevils.

MEADOW RUE. See *Thalictrum.*

——— SAFFRON. See *Colchicum.*

——— SAXIFRAGE. See *Peucedanum.*

——— SWEET. See *Spirea.*

MEDICAGO SATIVA. *Purple Medick* or *Lucern.* Probably not a native of England.

MEDICAGO FALCATA. *Yellow Medick* or *Yellow Lucern.* Dry paſtures and way ſides. This has been recommended for cultivation. It varies much in the colour of its flowers, and even produces them blue and yellow on the ſame ſtalk.

MEDICAGO LUPULINA. *Hop* or *black Medick.* Cultivated under the names of *Trefoil, Black ſeed* and *Black Nonſuch*; our old writers call it *Melilot Trefoil.* Common on dry banks and hilly paſtures, chiefly in a dry ſoil; flowering in june and july.

MEDICAGO POLYMORPHA ARABICA. *Heart Medick, Spotted Medick, Heart Trefoil, Heart Clover* or *Clover.* Common on banks and borders of fields, in dry ſandy paſtures, eſpecially near the ſea; flowering in may and june. Known by the dark-brown or blood-coloured ſpot on the leaves, ſhaped like the heart or head of an arrow.

It frequently appears among Lucern, Saint-foin, and Trefoil. On account of the roughneſs of the ſeeds, it ſhould be cut when young.

The *Medicagos*, like the Trefoils, have ternate leaves, but differ much in the ſeeds.

MELAMPYRUM PRATENSE. *Meadow Cow-wheat.* Woods and woody paſtures. Linneus obſerves that cattle are very fond of this plant, and that butter is good where it abounds.

MENTHA. *Mint.* Several ſpecies are wild in hedges, ditches, marſhy and watery places, the banks of rivers, and wet paſtures. *M. arvenſis* or *Corn Mint*, as the name implies, grows in arable land, and is a very bad weed.

MERCURIALIS PERENNIS. *Dog's-Mercury.* Common under hedges, ſeldom in the body of a paſture, except where there are buſhes to protect it; flowering from the end of march to the middle of may. Suppoſed to be poiſonous. Linneus ſays it is noxious to ſheep. With us it does not ſeem to be eaten by any quadruped.

Engliſh Mercury, which is ſometimes eaten as Spinach, is a ſpecies of *Chenopodium*.

MILFOIL. See *Achillea*.

MILKWORT. See *Polygala*.

MINT. See *Mentha*.

MOUSE-EAR SCORPION-GRASS. See *Myoſotis*.

MYOSOTIS SCORPIOIDES. *Mouſe-ear Scorpion-graſs.* One variety in dry paſtures; and another in wet meadows or marſhy grounds, commonly by the ſide of water. Linneus ſays, the latter is noxious to ſheep; but I ſuſpect that they never eat it.

NEPETA CATARIA. *Common Catmint* or *Nep.* In hedges, but not in the body of the paſture: chiefly in a calcareous ſoil. Not eaten by domeſtic animals.

NETTLE, DEAD. See *Lamium*.

NONESUCH. See *Medicago*.

NUT, EARTH or PIG. See *Bunium*.

ONONIS SPINOSA. *Thorny Reſt-harrow, Cammock, Petty Whin, Ground Furze*; in Suffolk *Lond-Whins* or *Land-Whins*; in ſome counties *Whin* is pronounced *Fin*: in Yorkſhire *Ruſt-burn*, that is *Reſt-bourn*. Barren paſtures, both in a light and ſtrong ſoil. It has a ſtrong creeping root, which makes it difficult to be rooted out, but renders this plant very fit to be ſown on ſea and ſen banks. It has ſtout thorns at the baſe of the branches, and handſome red pea-bloom flowers. Linneus's account is, that kine and goats eat it, ſheep are fond of it, horſes and ſwine refuſe it: horſes however will eat the younger ſhoots. A decoction of the roots has been recommended in the ſtone and jaundice.

We have another ſort (Ononis arvenſis) hairy and thornleſs, in like ſituations.

OPHIOGLOSSUM VULGATUM. *Common Adder's-tongue.* Moiſt meadows.

OPHRYS SPIRALIS. *Spiral Ophrys* or *Triple Ladies traces.* On heaths and commons.

OPHRYS OVATA. *Common Ophrys* or *Tway-blade.* Meadows and heaths, but more frequently in woods and moiſt thickets.

Ophrys muſcifera or *Fly Ophrys*; O. apifera or *Bee Ophrys*; and Oaranifera or *Spider Ophrys* are found among graſs, chiefly in chalky paſtures.

ORCHIS BIFOLIA. *Butterfly Orchis.* Woods, but ſometimes in paſtures among buſhes.

O. pyramidalis. *Pyramidal Orchis.* Calcareous paſtures, Known by the ſhape of the ſpike. Flowers very numerous, deep fleſh-colour or pale purple, ſometimes white.

O. morio. *Female* or *meadow Orchis.* Common in meadows moderately dry, with the Cowſlip. Flowers few, purple.

O. maſcula. *Male* or *early ſpotted Orchis.* Common in meadows and woods. As tall again as the preceding, with ſpotted leaves and more numerous flowers.

O. uſtulata. *Dwarf Orchis.* Chalk downs. Diſtinguiſhed by its ſmall dotted flowers.

O. militaris. *Man Orchis.* Calcareous paſtures.—Very different from Ophrys anthropophora or *Man Ophrys*, which is found in like places.

The above have a double bulb to the root; the ſucceeding ones have palmate bulbs.

O. latifolia. *Broad-leaved* or *Marſh Orchis.* Wet meadows and marſhes.

O. maculata. *Spotted Orchis.* Moiſt meadows and woods; ſometimes in barren paſtures, with the ſpike only half the ſize and fewer flowers.

O. conopſea. *Long-ſpurred Orchis.* An elegant ſpecies, diſtinguiſhed by the length of its ſpurs. It has ſome reſemblance to O. *pyramidalis*, but differs in the root, the narrowneſs of the leaves, and length of the ſpike.

Salep is prepared from the roots of ſome ſpecies of Orchis: they all ſeem to have the ſame quality.

ORNITHOGALUM. *Star of Bethlehem.* Two or three ſpecies are found in orchards and paſtures; but they are not common, and are doubtful natives, like many other bulbs.

ORNITHOPUS PERPUSILLUS. *Common Bird's-foot.* Dry heaths, commons and downs, on banks and by road ſides; flowering from may to ſeptember. A very ſmall plant.

OX-EYE DAISY. See *Chryſanthemum*.

PAGILS. See *Primula*.

PARSNEP. See *Paſtinaca*.

PASQUE-FLOWER. See *Anemone*.

PASTINACA SYLVESTRIS. *Wild Parſnep.* In paſtures and on the borders of corn fields; flowering in july. Biennial. Flowers yellow.

PEDICULARIS PALUSTRIS. *Marſh Louſewort.* Wet meadows. Said to make ſheep ſcabby, and louſy.

P. ſylvatica. *Common Louſewort*, or *red Rattle.* A much ſmaller plant in moiſt paſtures and heaths.

PENNY GRASS. See *Rhinanthus*.

PETASITES. See *Tuſſilago*.

PEUCEDANUM SILAUS. *Meadow Saxifrage.* Moiſtiſh meadows. Flowering in july and auguſt. An umbellate plant.

PICRIS ECHIOIDES. *Rough Picris* or *common Ox-tongue.* And P. hieracioides, *Yellow Succory* or *Hawkweed Ox-tongue.* Both among graſs on the borders of corn fields. Flowers yellow.

PILEWORT. See *Ranunculus*.

PIMPINELLA SAXIFRAGA. *Burnet Saxifrage.* Dry paſtures. A perennial umbellate plant, flowering in auguſt.

PLANTAGO MAJOR. *Great Plantain.* P. media, *hoary Plantain*, and P. lanceolata, *ribwort Plantain.* Paſtures and by way ſides. The laſt is now cultivated under the name of Ribwort.

POLYGALA VULGARIS. *Common Milkwort.* Paſtures, heaths and commons, flowering in june and july. Perennial. Flowers blue, varying to purple, fleſh-coloured and white. Cows and ſheep are ſaid to eat it, and it is a notion that it increaſes milk. The powdered root is good in the pleuriſy; and an infuſion of the herb, which is bitter, is uſeful in a catarrhous cough, about a quarter of a pint faſting every morning.

POLYGONUM BISTORTA. *Biſtort* or *Snakeweed.* Moiſtiſh meadows. Perennial. Root very aſtringent, and would probably tan leather. Not very common, but in ſome places occupies excluſively large patches of ground.

Several ſpecies of Polygonum or Perſicaria, vulgarly called *Arſmart*, are common in ditches, ponds and marſhes. P. Perſicaria or *Willow-weed* grows alſo in paſtures, on dunghills, &c.

POLYGONUM AVICULARE. *Knot-graſs, Swine's-graſs, Hogweed*, in the north *Bird's tongue.* Corn fields, way ſides, and in paſtures where dung has been laid, ſpreading very much. All quadrupeds eat it, and ſmall birds are very fond of the ſeeds.

P. convolvulus. *Black Bindweed*, or *climbing Snakeweed.* Corn fields, gardens and hedges, but ſeldom among graſs.

POPPY SPATLING. See *Cucubalus*.

POTENTILLA ANSERINA. *Silver-weed, Wild Tanſey, Gooſe Tanſey, Gooſe-graſs, feathered Cinquefoil.* Way ſides and low paſtures, eſpecially where water ſtands in winter. Perennial. June and july. Leaves white. Flowers yellow. Swine are fond of the roots, which taſte ſomewhat like Parſneps. Sheep refuſe the herb, but other cattle are ſaid to eat it: with us it ſeems generally untouched. The powder of the dried leaves is given in the ague.

Potentilla reptans. *Common Cinquefoil* or *five-leaved graſs.* Paſtures and road ſides. A decoction of the red bark of the root is a good gargle for looſe teeth and ſpongy gums.

There are other ſpecies, but not common.

POTERIUM SANGUISORBA. *Common, ſmall* or *upland Burnet.* Dry calcareous paſtures. Recommended

to be cultivated for ſheep.—Great Burnet ſee under *Sanguiſorba*.

PRIMROSE. See *Primula*.

PRIMULA VULGARIS. *Common Primroſe*. In woods, hedges, thickets and heaths among buſhes.

P. elatior. *Ox-lips* or *great Cowſlips*. Woods, hedges, and ſometimes in paſtures.

P. officinalis. *Cowſlips, Pagils* or *Paigles*. In Yorkſhire *Cow ſtriplings*. Common in meadows and paſtures in loamy or clayey ſoils, flowering in april and may.

PRUNELLA VULGARIS. *Common Self-heal*. Meadows and paſtures. Flowers blue, varying to purple and white.

PTERIS AQUILINA. *Female Fern, Common Brakes*. On commons and in woods.

RAGWORT. See *Senecio*.

RAMSONS. See *Allium*.

RANUNCULUS FICARIA. *Common Pilewort, leſſer Celandine*. Common in meadows. Differs from the other ſpecies in having eight or nine petals. Root compoſed of oblong tubers. Flowers early in march or april.

R. Flammula, and Lingua. *Small* and *great Spearwort* or *Crowfoot*. In boggy meadows, and by the ſides of pools and ſtreams.

R. repens, bulboſus and acris. *Creeping, bulbous* and *upright Crowfoot*, or *Crowflower*; common in meadows, and confounded under the names of *Butter-cups, Butter-flowers, Gold-cups, King-cups, Gold-knobs*. Flowers of a fine ſhining yellow, vulgarly ſuppoſed to give a yellow colour to butter, but falſely, for cattle do not eat the flowering ſtems. But as they indicate good land, they may mediately indicate good butter.

Theſe plants, though very acrid, are thought by ſome to be a grateful and uſeful admixture in hay, correcting the flatulent nature of graſs. Mr. Marſhall informs us, that in the vale of Glocester, the *creeping* Crowfoot is eſteemed as valuable herbage, whilſt the two others, being extremely acrid, are conſidered as very pernicious, eſpecially among hay. This is worth enquiring into.

Other ſpecies grow by water ſides, in water and in marſhes. Ranunculus auricomus is common in woods; and arvenſis among corn. It is ſaid that the latter is fatal to ſheep, and that three ounces of the juice killed a dog in four minutes.—It is certainly a very ſuſpicious genus.

RATTLE, RED. See *Pedicularis*.

——— YELLOW. See *Rhinanthus*.

RESEDA LUTEOLA. *Wild Woad, Dyer's-weed* or *Yellow-weed, Weld, Would* or *Weld*. Meadows, paſtures, walls, and barren uncultivated ſpots. Annual, flowering in june and july. Cultivated in ſight ſoils for the dyers. Very different from the Iſatis or true Woad uſed in dyeing blue, and as the baſe of other colours.

Reſeda lutea. *Baſe Rocket* or *Rocket Yellow-weed*. Paſtures, chiefly in a calcareous ſoil, in corn fields, and ſometimes on walls.

REST-HARROW. See *Ononis*.

RHINANTHUS CRISTA GALLI. *Yellow Rattle, Cock's-comb, Penny-graſs, Penny-weed*, or *Henpenny*. Meadows and woods. Annual; flowering in june. This keeps its ground, for the ſeeds are ripe at the uſual time of cutting hay. They are ſaid to be very nutritive.

RIB-GRASS or *Ribwort*. See *Plantago*.

RUMEX. *Dock*. Theſe are univerſally reprobated as ſome of the worſt of weeds. Three ſorts are common in paſtures—Rumex criſpus or *Curled Dock*; common among Clover. R. acutus or *Sharp-leaved Dock*, the roots of which are uſed in dyeing. R. obtuſifolius or *Broad-leaved Dock*, in farm yards, among dung and rubbiſh, and by the ſides of ditches, carried into paſtures with dung, or ſpreading by root and ſeed from dunghills. Theſe ſorts are perennial, and flower from june to auguſt.

RUMEX ACETOSA. *Common Sorrel: Green-Sauce: Sour-docken* in Yorkſhire. Abundant in paſtures. Eaten by all quadrupeds. Cultivated in France for the table. Much eaten in Ireland. The dried root gives out a beautiful red colour when boiled.

Rumex Acetoſella. *Sheep's Sorrel*. Sandy paſtures.

Rumex paludoſus or *Marſh Dock*; and R. Hydrolapathum or *Water Dock*, a medicine of conſiderable efficacy; grow in marſhes and on the banks of rivers.

RUSH. See *Juncus*.

SAGE. See *Salvia*.

SAINT-FOIN. See *Hedyſarum*.

SAINT-JOHN'S-WORT. See *Hypericum*.

SALVIA PRATENSIS. *Meadow Sage* or *Clary*: and Verbenaca, *Wild Sage* or *Clary*. Both in dry paſtures.

SANGUISORBA OFFICINALIS. *Great* or *Meadow Burnet*. Moiſt paſtures, eſpecially in a calcareous ſoil; flowering from june to auguſt. A coarſe woody plant, from eighteen inches to above two feet in height. Not fit for feeding, like the ſmall Burnet, which ſee under *Poterium*.

SAPONARIA OFFICINALIS. *Common Soapwort* or *Bruiſewort*. Hedges and ſometimes in meadows. Bitter. Will lather in water like ſoap. Uſed inſtead of Sarſaparilla in Germany and France. Perennial: flowering in july and auguſt.

SATYRIUM. Several ſpecies of *Satyrion* grow in meadows, but not common. They are of the Orchis tribe.

SAW-WORT. See *Serratula*.

SAXIFRAGA GRANULATA. *White Saxifrage* or *Scurvygreen*. Dry paſtures; flowering in april and may. Root compoſed of a cloſe bunch of little tubercles. Flowers white, large for the plant.

SCABIOSA SUCCISA. *Devil's-bit*: ſo called from the root being as it were bit off. Flowers in globular heads; blueiſh purple, varying to fleſh-coloured and white. Common in paſtures; flowering from june to auguſt.

SCABIOSA ARVENSIS. *Field Scabious*. Both paſtures and corn fields; flowering in july and auguſt. Flowers blue, purple or white, a little woolly; the outer ones larger, with four unequal clefts; the inner ones regular. Slightly aſtringent, bitter and ſaponaceous.

SCABIOSA COLUMBARIA. *Small Scabious*. Frequent in dry hilly paſtures: flowering from june to ſeptember. Flowers blueiſh lilac.

SCABIOUS, SHEEP'S. See *Jaſione*.

SCORPION-GRASS. See *Myoſotis*.

SELF-HEAL. See *Prunella*.

SENECIO JACOBÆA. *Ragwort, Ragweed, Staggerwort, Stanerwort, St. James's-wort, Seggram* or *Seagrim*. Perennial; flowering in july. Common in paſtures and by road ſides.

Senecio vulgaris. *Common Groundſel*. Abundant in cultivated ground, but ſeldom in paſtures, being annual. According to Linnæus ſwine and goats eat it; but horſes and ſheep refuſe it. In this he is miſtaken, for both horſes and ſheep eat it.

SERRATULA ARVENSIS. Carduus arvenſis. *Way Thiſtle*. Every where, in good land: in paſtures, corn fields, by road ſides, &c. Aſſes alone eat it, except ſometimes the tops, when tender. Few of the Thiſtles are perennial except this.

SILVER-WEED. See *Potentilla*.

SORREL. See *Rumex*.

SPIRÆA FILIPENDULA. *Dropwort*. So named from its tuberous roots. Common in high paſtures in a calcareous ſoil: flowering in june and july. Hogs are fond of the roots.

SPIRÆA ULMARIA. *Meadow-ſweet, Queen of the meadows*. Moiſt meadows, and the banks of ſtreams. Flowering at the ſame time. Swine, ſheep and goats are ſaid to eat it; kine and horſes to refuſe it.

STELLARIA GRAMINEA. *Leſſer Stichwort*. Paſtures and hedge-banks; flowering in may. Annual. Flowers upright, white, cloſing in rain. The young ſhoots and leaves as good as ſpring Spinach. Swine, cows and horſes eat it; and it is grateful to ſmall birds and young chickens.

The greater ſort, *Stellaria boloſtea*, is common in woods and hedges.

SUCCORY. See *Cichorium*.

TANACETUM VULGARE. *Common Tanſey*. High paſtures, banks of rivers and ſwampy places; flowering in june.

TARE. See *Vicia*.

THALICTRUM FLAVUM. *Common Meadow-Rue*. Moiſt paſtures and the banks of ſtreams: flowering in june.

Root

Root a full yellow. Flowers numerous, yellowiſh white.

There is a ſmaller ſort, *T. minus*, in high but moiſt paſtures, in a calcareous ſoil; flowering in july and auguſt.

THESIUM LINOPHYLLUM. *Baſtard Toad-Flax.* Dry heaths and hills in a calcareous ſoil; found alſo in looſe ſand. It is a ſmall plant, with flowers of no ſhow, and is in a manner loſt among the graſs.

THISTLE. See *Carduus* and *Serratula.*

THYMUS SERPYLLUM. *Mother of Thyme, Wild Thyme, Common Thyme.* Heaths, commons, downs, and high dry paſtures: flowering in july and auguſt. It ſeems a miſtake that ſheep feed upon it, but paſtures where this plant abounds are peculiarly adapted to ſheep, being dry and ſound. Bees are much attached to this and other aromatic plants.

TOAD-FLAX. See *Antirrhinum.*

————, Baſtard. See *Theſium.*

TORMENTILLA ERECTA. *Tormentil* or *Septfoil.* Barren paſtures, ſhady places and moors. It has four petals, and a calyx cut into eight parts; whereas Potentilla has five petals, and a ten-cleft calyx. The root is a ſtrong aſtringent, and is given to cattle in the dyſentery; it dyes red and tans leather.

TRAGOPOGON PRATENSE. *Yellow Goat's-beard* or *Go to bed at noon.* In meadows; flowering in june. Kine, ſheep and horſes eat it, ſwine are very fond of it.

TRAGOPOGON PORRIFOLIUM. *Purple Goat's-beard.* In ſome meadows, and in upland paſtures in ſome countries not unfrequent; flowering in may. The roots of both are eſculent; and the latter is cultivated under the name of *Salſafy.*

TREFOIL. See *Medicago* and *Trifolium.*

———— Bird's-foot. See *Lotus.*

TRIFOLIUM MELILOTUS OFFICINALIS. *Melilot Trefoil* or *common Melilot.* In meadows and on ditch banks, but rather a corn than paſture weed.

TRIFOLIUM REPENS. *Creeping* or *White Trefoil* or *Clover, Dutch Clover.* Meadows and paſtures in a good ſoil. Much cultivated.

TRIFOLIUM PRATENSE. *Purple Trefoil, Honeyſuckle Trefoil, Clover-graſs* or *Red Clover.* Meadows and paſtures. The *cultivated red* or *broad Clover* and the *Marl-graſs*, are nothing but varieties of this.

TRIFOLIUM OCHROLEUCUM or *Brimſtone Trefoil*, and ſeveral ſmaller ſorts, are common in dry paſtures.

TRIFOLIUM FRAGIFERUM or *Strawberry Trefoil* is common in moiſt meadows.

TRIFOLIUM PROCUMBENS and FILIFORME. *Hop Trefoils.* Dry paſtures. Not *T. agrarium* of Linneus.

TRIGLOCHIN PALUSTRE. *Arrow-headed Graſs*; *Marſh Arrow-Graſs.* Wet meadows. Cows are fond of it; other quadrupeds eat it.

Triglochin maritimum. *Sea Arrow-Graſs.* In ſalt-marſhes. All domeſtic quadrupeds reliſh it.

TROLLIUS EUROPÆUS. *Globe-flower, Gowlans Globe-flower, Locker-gowlans.* Mountainous meadows in Wales and the north of England. Moiſt woods in Yorkſhire. Marſhes in Durham.

TURRITIS GLABRA. *Smooth Tower-Muſtard*, or *Tower-wort.* Paſtures and waſte places, in a gravelly ſoil.

Turritis hirſuta. *Hairy Tower-wort* or *Wall Creſs.* Dry mountainous paſtures.

TUSSILAGO FARFARA. *Common Colt's-foot.* Paſtures and other places in moiſt ſtiff clayey ſoil, and on limeſtone rubbiſh; flowering in march and april. It indicates a ſubſoil that holds wet.

TUSSILAGO PETASITES. *Butter bur* or *Peſtilent-wort.* Moiſt meadows, and banks of ſtreams. Theſe both flower in march, before the leaves appear.

VALERIANA DIOICA. *Marſh Valerian.* Wet meadows and by the ſides of ditches and ſtreams.

VALERIANA OFFICINALIS. *True Valerian.* A large variety in hedges and woods. The ſmaller, which is in ſo much repute as a medicine, is found on dry heaths and high paſtures, particularly in a calcareous ſoil. The root is excellent in hyſterical caſes and even in epilepſies, and in habitual coſtiveneſs. Cats are well know to be very fond of it; and it is ſaid that rat-catchers employ it to draw the rats together. Roots from a garden, or from woods and hedges are good for nothing.

VALERIANA LOCUSTÆ. *Lamb's Lettuce* or *Corn-ſalad.* Not only in corn-fields, but on banks, and ſometimes in paſtures. The young leaves are eaten in ſalads.

VERONICA OFFICINALIS. *Common* or *Male Speedwell* or *Fluellin.* Dry barren paſtures, heaths and downs; flowering from may to auguſt.

Veronica ſerpyllifolia. *Smooth Speedwell* or *Paul's Betony.* A little plant not uncommon in paſtures.

Veronica Chamædrys. *Wild Germander* or *Germander Speedwell, Bird's-eye.* Paſtures, but moſtly in hedges and among buſhes. A very elegant blue flower. The leaves are a better ſubſtitute for tea than V. officinalis. It flowers in may.

VETCH. See *Vicia.*

VICIA CRACCA. *Tufted Vetch.* In hedges, ſhady places, meadows and willow beds; flowering in july and auguſt. Perennial. Flowers ſmall, numerous, blueiſh purple, with two deeper purple ſpots at the extremity of the keel; on a long fruitſtalk.

VICIA SATIVA. *Common Vetch, Fetch*, or *Tare.* Dry paſtures; flowering from april to june. Annual. Commonly cultivated. Winter and ſpring Tares only varieties.

VICIA SEPIUM. *Buſh Vetch.* Woods, hedges and paſtures; flowering in may and june. Perennial. Flowers three or four together, dirty purple, on very ſhort ſtalks.

VICIA LATHYROIDES. *Strangle Vetch* or *Tare.* Dry paſtures, gravel-pits and corn-fields; flowering in may. Annual. The tendrils are ſeldom or ever branched; the corolla is ſcarcely longer than the calyx, ſmall and of a bluiſh purple, and the ſeeds are cubic.

WILD WILLIAMS. See *Lychnis.*

WILD WOAD. See *Reſeda.*

YARROW. See *Achillea.*

The above liſt might eaſily have been increaſed, by the inſertion of ſome plants occaſionally found among Graſs, or of others that are rare; but that is not the deſign of it. Some perſons will probably think that many, which are rather hedge-plants, might have been omitted; but they form a part of the produce of the Paſture ground, and are apt to find their way into the Graſs itſelf.

Of the 228 plants, or thereabouts recited above, the following are uſeful as food or medicine for quadrupeds. Cardamine pratenſis, Rumex Acetoſa, Tragopogon, and moſt of the leguminous plants, as Lotus, the Vetches in general, the Medicagos, and the Trifoliums, or Trefoils properly ſo called. Milfoil, Sucory, and Ribwort, which are weeds in their wild ſtate, are ſo much improved by cultivation as to become uſeful plants. Many in the liſt, perhaps moſt of them, are beneficial in ſome reſpect or other, though not immediately to cattle. Some of their uſes are pointed out in the remarks.

The Paſture herbs chiefly injurious are Allium vineale and urſinum. Anemone nemoroſa. Bellis perennis or Daiſy, in occupying much room. Caltha paluſtris. The different ſpecies of Thiſtle. The various ſpecies of Carex or Sedge. Centaurea nigra or Knobweed, and Calcitrapa or Star-Thiſtle, Chærophyllum or Cow-weed. Chryſanthemum Leucanthemum or Ox-eye Daiſy. Colchicum or Meadow Saffron. Heath. Heracleum Sphondylium or Cow-Parſnep, which however might be a very uſeful plant if cultivated. Inula dyſenterica. The Ruſhes. Mercurialis perennis or Dog's Mercury. Pedicularis or Red Rattle. Pteris, female Fern or Brakes. Several ſorts of Ranunculus. Rhinanthus Criſta galli, or Yellow Rattle; almoſt the only annual plant that keeps its ground in Paſtures to any great extent; which it does by ſeeding early. It can only be kept down by paſturing the ground wo years ſucceſſively. Other annuals, ſuch as Purging Flax, the Eye-brights, ſome of the Hawkweeds, and Sheep's-Scabious, being of little conſequence. The Docks. Senecio Jacobæa or Ragwort. The other plants in the liſt may be conſidered as in great meaſure neutral, or as doing little harm or good as Paſture herbs.

With reſpect to the extirpation of the moſt noxious of theſe weeds, the Docking-iron, the Spud, and the Hand

Hand ſhould be unremittingly employed on fit occaſions.

The biennial Thiſtles may be cut off within the ground, and if not ſuffered to ſeed may eaſily be deſtroyed; unleſs they are reinſtated from the nurſeries in hedge-rows, way-ſides, &c.

Carduus acaulis. Stemleſs or dwarf Carline Thiſtle ought to be diligently cut up with the ſpud: but it infeſts only dry upland Paſtures.

Way-Thiſtle, or as ſome in anger call it, Curſed Thiſtle, (Serratula arvenſis) is a true perennial, and runs dreadfully at the root; thus increaſing two ways, by root and ſeed. It is rather an arable weed, and is attempted in vain to be extirpated by ploughing three inches deep. But it is alſo too common on rich paſtures, in the neighbourhood of arable lands, headlands and way-ſides, where it is ſuffered to ſeed without controul.

In mowing grounds it is ſeldom ſuffered to ſeed, but I believe mowing contributes to ſpread it, though I know it is the opinion of ſome that this operation will in time deſtroy it, at leaſt if it be cut down whilſt in flower. This is contrary to my preſent experience, which I mean to purſue farther. The only radical cure for the evil in paſtures, is to extricate the plants by the docking-iron and the hand after rain, when alone they will pull out, and even then ſeldom completely. The ground therefore muſt be looked over carefully a ſecond time, to take out thoſe Thiſtles which have ſprung up from pieces of roots left in, on the firſt operation.

The Carices or Sedges, the Junci or Ruſhes, Caltha or Marſh Marygold, Iris or Flag, Pedicularis or Red Rattle, the whole tribe of water plants, and ſuch as require a ſoil tenacious of wet, can only be effectually deſtroyed by judicious draining, and dreſſing with coal aſhes, and other warm manures.

Fern or Brakes muſt be extirpated by paring and burning. The Docks, together with Senecio Jacobæa or Ragwort, and Centaurea Jacea or Knobweed, will yield only to the docking-iron and the hand, and ſhould never be ſuffered to ſeed: notwithſtanding it is a notion, as Mr. Marſhall informs us, in ſome of the midland counties, that the beſt way to get rid of Docks on Graſs land is to let them ſpend themſelves by ſeeding. If the old plant be thus ſpent, it leaves an innumerable progeny to repreſent it. Mr. Marſhall ſays that Knobweed and Ragwort may both be cured by repeatedly paſturing with ſheep.

Improvement of Paſture Land.

1. By Draining and Watering; for both which ſee MEADOWS.

2. By Weeding and Top-dreſſing.

3. By laying the land ſo as to clear itſelf of ſurface water, levelling ant-hills and other inequalities, and running a heavy roller over it in the ſpring.

4. By putting on different ſtock at proper ſeaſons, ſo that the herbage may be kept fine by being cloſe bitten, and the ſurface regular by not being poached in wet times by heavy cattle[9].

Not a weed, ſays Mr. Marſhall, ought to ſeed, nor a tuft of ſtale graſs be ſuffered to ſtand in a Paſture ground; which ſhould at leaſt once during the ſummer be levelled with the ſcythe; thus at a ſmall expenſe, converting weeds into nutriment, and waſte ground into after-graſs. See GRASS and MEADOWS.

PATAGONICA and PATAGONULA. See *Cordia*.

PATIENTIA. See *Rumex*.

PAVEL. See *Momordica*.

PAVETTA. (*A vernacular name of the Eaſt Indies.*)

Lin. gen. n. 132. *Reich. n.* 138. *Schreb. n.* 168. *Gærtn. t.* 25. *Juſſ.* 203.

Claſſ. 4. 1. Tetrandria Monogynia.

Nat. order of *Stellatæ*. *Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* bell-ſhaped, very ſmall, obſoletely four-toothed, ſurrounding the germ.

COR. one-petalled, funnel-form: *tube* long, ſlender, cylindric: *border* five-parted, ſpreading, ſhorter by half than the tube: *ſegments* lanceolate.

STAM. *Filaments* four, very ſhort, above the throat of the corolla. *Anthers* awl-ſhaped, ſpreading, the length of the border.

PIST. *Germ* inferior, turbinate. *Style* filiform, twice as long as the corolla. *Stigma* thickiſh, oblong, oblique.

PER. *Berry* roundiſh, one-celled.

SEEDS two, convex on one ſide, cartilaginous.

OBS. *Berry two-celled. Seeds ſolitary, one often abortive, ſo that the fruit ſeems to be one-ſeeded. There are frequently two coadunate berries, crowned with a double calyx.* Gærtn.

ESSENTIAL CHARACTER.

Cor. one-petalled, funnel-form, ſuperior. *Stigma* curved. *Berry* two-ſeeded; (one often abortive.)

SPECIES.

1. Pavetta indica.
   Lin. ſpec. 160. *Jacq.* 153. *Reich.* 312. *Willd.* 610. *ſuppl.* 121. *fl. zeyl. n.* 56. *amœn.* 1. 388. *Gærtn. fruct.* 1. 116. *Burm. ind.* 35. *t.* 13. *f.* 3. *Plum. phyt. t.* 147. *f.* 1.—alba. *Vahl ſymb.* 3. 11.

   Jaſminum arboreſcens ſolani fol. baccis nigro-violaceis. *Plum. ic. t.* 156. *f.* 1. *Tourn. inſt.* 598.
   Leaves oblong-lanceolate acuminate, panicle trichotomous axillary, flowers five-ſtamened.
6. Pavetta arenoſa.
   Lour. cochinch. 73.
   Branches brachiate, leaves tubercled oppoſite.
7. Pavetta paraſitica.
   Lour. cochinch. 73.
   Stem paraſitical, leaves in whorls, flowers in little axillary balls.

DESCRIPTIONS, &c.

1. Corymbs trichotomous, faſtigiate, on a long filiform peduncle. Stigma oblong, bifid[8]. Berry inferior, fleſhy, ſubglobular or ſubturbinate, ſimple or twin, crowned with the minute whitiſh calyx, two-celled, by age becoming black: pulp thin, wholly fungoſe in the old fruit, adhering cloſe to the ſeeds; of which there is one in each cell, ſubglobular, convex on one ſide, flattiſh on the other, with a longitudinal cleft, and within this having a very wide cavity, ſmooth, black; albumen cartilaginous[9].

Native of the Eaſt Indies.—Gærtner ſuſpects that the natural number of flowers is two together, as in ſome ſpecies of Lonicera.

2. Branches oppoſite, four-cornered, jointed, denſely villoſe, hoary; the laſt joints more compreſſed. Leaves on ſhort petioles, oppoſite, two or three inches in length, acuminate, attenuated at the baſe, quite entire, the younger ones villoſe on both ſides, hoary; the older almoſt ſmooth above, nerved, veinleſs. Stipule

[9] Agricult. report for Staffordſhire.

[8] Linn.

[9] Gærtner.

oblong.

oblong, blunt, almoſt the length of the petiole, opening on one ſide. Calyx hoary. Corolla ſmooth, four times as long as the calyx. Style thickened towards the top.

3. The ſtipulation, ſtigma and fruit are thoſe of *Pavetta*. It may be doubted whether it is any thing more than a variety of the preceding. The branches and leaves are quite ſmooth; the calyx has a few ſmall hairs ſcattered over it, not viſible without a magnifier. Corolla an inch and half in diameter, in other reſpects like the former. It differs from the firſt ſpecies in having the ſtipules hairy on the inner ſide; the flowers twice as large, the calyxes four-cleft, not obſcurely four-toothed.—Theſe were both found in Arabia Felix by Forſkahl[1].

4. This is a ſmooth tree with round branches. Leaves oppoſite, petioled, veined. Head of flowers ſeſſile, terminating the ſhorter branchlets. Receptacle hairy. Flowers ſuperior. Calyx four-leaved; leaflets awl-ſhaped, ſpreading. Tube of the corolla ſcarcely longer than the calyx: border four-parted, regular; ſegments lanceolate. Berry two-ſeeded. Seeds oblong, convex on the outer, flat on the inner ſide. Flowers in the dried plant black.—Native of the Cape of Good Hope[2].

5. This is a ſhrub, with a ſtem the height of a man, upright, branched, even. Branches ſtiff, round, ſmooth. Leaves petioled, oppoſite, acuminate, entire, nerved, ſmooth only a little wrinkled, thin. Petioles of a middling length, round, ſmooth. Stipules ſmall, membranaceous, interpetiolary, two-toothed on each ſide. Corymb terminating, on a ſhorter common peduncle; the branches brachiate, trichotomous, ſpreading, round, ſmooth; pedicels one-flowered. Flowers white, very ſweet-ſcented. Perianth with five awl-ſhaped teeth. Tube of the corolla near an inch long, ſeldom curved: throat naked. Filaments five, filiform, from the middle of the tube. Anthers linear, in the throat. Germ oblong. Style longer than the corolla. Stigmas two, pubeſcent. Seeds roundiſh-dicoccous, the ſize of a pea, crowned, two-celled, black when ripe. Seeds ſolitary, hemiſpherical, flat within, grooved. It flowers in the ſpring; and is commonly called in Jamaica *Wild Coffee*. It is as it were a middle ſpecies between *Pſychotria*, *Coffea*, and *Pavetta*, which are very nearly allied: but it ſeems to approach neareſt to the laſt in its inflorescence, and the form of the flowers, although they have five ſtamens. *Siderexyloides ferreum* of Jacquin, *amer.* 19. which is *Sideredendrum*, *Schreb. gen. n.* 169. is allied to this.—Native of the Weſt Indies[3]. See Mr. Miller's deſcription in *Ceſtrum nervoſum*.

6. This alſo is a ſhrub, unarmed, upright, four feet high, with many brachiate reclining branches. Leaves lanceolate, quite entire, ſhining, with many prominent tubercles on each ſide, which make them appear as if they had ſand ſprinkled on them; whence it is called in Chineſe the *Sand plant*. Flowers white, terminating, faſtigiate; with a berried five-toothed calyx. Corolla ſalver-ſhaped, with a long tube, and a five-cleft border. Filaments ſcarcely any. Anthers four, linear, ſtanding out at the mouth of the tube. Berry ſmall, ovate, inferior, containing one ovate-oblong ſeed.—Native of China, near Canton.

7. Stem perennial, woody, a foot high, very much branched. Leaves ovate, tomentoſe, quite entire. Flowers duſky-yellow, ſmall, villoſe. Calyx oblong, four-cornered, truncated, villoſe; ſupported by an oblong reflex ſcale. Corolla ſalver-ſhaped, with a long tube, and a ſmall four-cleft border; ſegments oblong, bent in. Filaments four, growing to the mouth of the tube, ſhorter than the border. Germ calycine, oblong. Style equal to the corolla. Berry ſmall, ovate-oblong, with one ovate ſeed.—Frequent on trees in the gardens of Cochinchina[4].

To avoid confuſion, Loureiro would place ſuch of theſe plants as have a one-ſeeded berry in this genus; ſuch as have a two-ſeeded berry in that of *Ixora*; and thoſe which have a one-celled two-ſeeded berry in a new genus which he names *Pohyozus*.

Lin. ſyſt. 380. *Reich.* 2. 219. *Jacqu. obſ.* 3. 12. *t.* 62. *f.* 14.
Leaves ſuperdecompound, petioles margined, the loweſt pinnate, the reſt ternate.

DESCRIPTIONS, *&c.*

Theſe are climbing ſhrubs, throwing out long ſhoots annually like the Vine. Leaves ternate (1 to 4), biternate (5 to 10), triternate (11, 12), unequally pinnate (13 to 16), or ſuperdecompound (17). Peduncles ſolitary, axillary, having two tendrils in the middle, and beyond many-flowered in racemes[r]. The chief of what we know on this genus is derived from Jacquin and Plumier.

1. Stem round, covered with prickles. Leaves alternate, on a long ſtout petiole, on which alſo is ſometimes a prickle; leaflets oval-lanceolate, entire, ſmooth, bright green above, paler and almoſt aſh-coloured underneath. Peduncles very long and ſtout, prickly. Fruit commonly tricoccous, but ſometimes quadricoccous and even pentacoccous, ſaffron-coloured with black ſpots, of an acrid taſte with ſome ſweetneſs. Seed kidney-form, gray or aſh-coloured[s]. Flowers white, ſmelling ſtrongly[t].

Native of the Eaſt Indies.—See CRANZIA and SCOPOLIA.

2. The leaflets are often on ſhort petioles and not ſo much ſituated as in Plumier's figure. The common petiole is ſometimes three inches long[u].

Capſule ovate, three-winged: valves navicular, coriaceous, ſtriate-veined, ſomewhat tawny; partitions growing to the axis and correſponding with the ſutures of the valves. Seeds three-cornered-globular, ſmooth, ſhining, black; with a fungoſe umbilical ſcar, cordate two-lobed, cloſely adnate, white, clothed at the baſe. The receptacle is a white fungoſe tubercle, growing to the axis of the fruit, a little above the baſe of each cell[x].—Native of South America.

3, 4. Natives of South America.

5. Native of Mexico.

6. This has the leaves more cut than the other ſpecies; and they are very thin, whereas in the reſt they are more or leſs coriaceous and thick. It is entirely void of prickles[y].

Found by Plumier; and afterwards by Jacquin about Carthagena in New Spain, in coppices.

7. The branches and common petioles are armed with numerous recurved prickles. Leaflets ſubovate with very few inciſures.—Native of the Caribees[z].

8. Jacquin remarks that in Plumier's figure the petioles appear to be naked, they are all, however, except the common one margined, or winged at the edge, but ſo ſlightly, that it can hardly be expreſſed in a figure.—Native of Curaſſao.

According to Swartz, this is the *Paullinia* or *Souple Jack* of Browne, which he ſays is very common in the woods of Jamaica, with its ſlender, woody, flexile ſtalk, raiſing itſelf frequently to a very conſiderable height among the buſhes: it is ſo tough and yielding, that it is commonly cut into junks, barked and uſed for riding and walking ſticks. See *Paullinia polyphylla*. It was cultivated in 1739, by Mr. Miller[a].

9. This differs from the preceding principally in the form of the leaves, and in the ſlighter and leſs frequent inciſion of them[b].—Native of the Weſt Indies. Introduced in 1786, by Mr. Alexander Anderſon[b].

10. Native of Jamaica[c].

11. Native of the Weſt Indies. Cultivated in 1739 by Mr. Miller[b]: but not mentioned in the Dictionary.

According to the Kew catalogue, this is the *Supple-Jack*: and if Browne, by *foliis ternato-ternatis* means triternate leaves, his *Paullinia* is this ſpecies, and not *curaſſavica*, the leaves of which are biternate. His ſynonyms are confuſed.

12. This climbs trees to the height of twenty feet. Branches round, ſmooth, grooved, long, flexible. Leaves ſhining, alternate, numerous: ribs naked, channelled; leaflets acute, ſeſſile, unequally ſerrate-toothed above the middle; the lateral ones roundiſh, the outmoſt double the ſize, very much attenuated at the baſe; the proper petioles of each ternate leaf winged. Racemes axillary, four inches long, having about fifty flowers in them, naked for about two inches, and then divided into three parts, and putting out two tendrils, two inches long, ſmooth and flat. Common peduncles two lines long and alternate, putting forth ſmall flowers on very ſhort peduncles, uſually four in number. Calyx dirty white; corolla white; leaves of the firſt nectary white with yellow tips, at firſt ſight reſembling ſtamens.—Native of the iſland of St. Domingo, in woods[d].

13. Stem herbaceous, angular, climbing, ſmooth, ſcarcely the thickneſs of a ſtraw. Leaves alternate, ſmooth: lower leaflets ovate, ſubſeſſile, bifid or trifid, the inciſures entire, an inch long; middle leaflets ternate with a margined petiolet, lateral pinnas ovate, entire or cut, the middle one trifid; end leaflet pinnate, with a jointed, margined petiolet; pinnas two-paired, oblong, gaſh-trifid or quinquefid, the laſt trifid and larger. Petioles like the ſtem, two inches long. Flowers oppoſite to the leaves, panicled. Peduncles the

length

length of the leaves; pedicels very short.—Native of Japan [a].

14. Native of the West Indies [a].

15. Leaflets oblong-ovate, deeply and remotely serrate [a]. Capsule obovate, coriaceous and almost woody, very finely striated, of a dusky ferruginous colour: partitions membranaceous, very thin, growing to the axis; corresponding, not with the sutures, but with the middle of the valves. Receptacle fungose, above the base of the axis, as in *P. Seriana*. Seed ovate-oblong, smooth, shining, black. Umbilical scar fungose, white, very closely adnate, two-lobed, covering both sides of the seed beyond the middle [b].—Native of Brasil, Jamaica and Domingo, in dry sandy places.

The insertion of the seeds is the same in *Cururu* as in *Seriana*; but there is a remarkable difference between them in the situation of the partitions [b].

16. Common petioles margined, but not between the lower leaflets [a]. Calyxes tomentose, glaucous-brown, permanent.—Native of South America.

17. Native of South America [a].

PROPAGATION AND CULTURE.

Procure the seeds from the countries where they naturally grow. As soon as they arrive sow them in small pots filled with light earth, and plunge them into a moderate tan-bed. If the seeds arrive in autumn, plunge the pots in the bark-bed in the stove, and probably the plants may come up the following spring: but if they arrive in spring, plunge the pots into a moderate hot-bed under a frame, where they may be continued all the summer; in autumn remove them into the stove for the winter, watering them now and then sparingly. The following spring plunge the pots into a new hot-bed under a frame, which will bring up the plants in about six weeks, if the seeds are good. When the plants are fit to remove, plant each in a small pot filled with light earth, and plunge them into a hot-bed of tanner's bark, observing to shade them till they have taken new root; after which they should have free air admitted to them daily, in proportion to the warmth of the season. In the autumn they must be removed into the bark-stove, where they must constantly remain. As they require much room, and their flowers have little beauty, they are seldom propagated in Europe.

DESCRIPTIONS, &c.

These are annual plants, natives of the West Indies. Leaves opposite entire, often linear and dotted.

1. Root branched, with filiform radicles. Stem herbaceous, half a foot high, branched, dichotomous, diffused, round, smooth. Branchlets scattered, diffused, round, spreading, red. Leaves sessile, half embracing at the base, linear, acuminate; tooth-ciliate at the base, perforated at the edge, membranaceous-serrate when examined with a glass, nerveless, smooth. Pores pellucid. Peduncles terminating, or in the division of the branchlets, erect, solitary, filiform, one-flowered. Flowers small, yellow. Common calyx five-grooved, five-cornered, five-toothed: leaflets erect, concave, acute, converging. In the disk five-toothed corollets: those of the ray lanceolate, acute, spreading. Seeds striated, black; those of the disk with five, those of the ray with two bristles. Down none, but a membranaceous jagged rim. The leaves, when bruised, have a sweet smell, like Savoury.—Native of Hispaniola: flowering there in june.

2. Stem herbaceous, a foot high and more, angular, branched, smooth. Branches opposite, erect, axillary. Leaves erect, acute, long, almost entire, somewhat convex at the edge, having a few red ciliary hairs at the base; dotted with pellucid pores. Peduncles terminating, erect, solitary, one-flowered. Common calyx four-leaved or five-leaved: leaflets converging, linear, erect. Corollets of the disk four or five, with a four or five-cleft border. Style bifid at top. Stigmas blunt. Corollets in the ray four or five, three-toothed at top: style bifid to the middle. Stigmas reflex. Seeds linear, striated; with a three-bristled subulate down.—Native of Hispaniola, on sandy coasts [b].

Jacquin describes it as a tender upright plant, from two to three feet in height, with smooth striated dichotomous branches. Leaves attenuated to both ends, acuminate, quite entire, smooth above, dotted at the back, subsessile, an inch and half long. Peduncles almost the length of the leaves, at the divisions of the stalks, and sometimes axillary. Flowers small, dirty yellow, inodorous.—Every where about Carthagena in

[a] Thunberg. [b] Swartz. [c] Linn. [d] Gærtner. [e] Idem. [f] Linn. [g] Jacqu. obs. [h] Swartz.

New

New Spain, on the borders of woods; flowering in ſeptember and october.

3. Common calyx of five, ſix or ſeven narrow equal ſcales, joined together into a cylindric tube, containing ſo many female ligulate florets, diſpoſed very orderly round the margin; and a few hermaphrodites in the centre. The plant is ſpreading and ſlender, and ſeldom riſes above eighteen or twenty inches in height[a]. Receptacle narrow, hollow-dotted. Seeds uniform, a little thicker upwards, compreſſed, ſmooth, blackiſh. Down awned, with ſmooth, briſtly rays, in the ſeeds of the diſk two; in thoſe of the ray three, ſpreading, ſubſtuteſcent, ſhorter by a third part than the ſeed[b].—Native of the Weſt Indies, common in all the ſugar iſlands.

4. Native of Guadaloupe and Santa Cruz[c].

PECTIS. See *Bellium*.

PEDALIUM. (Πηδάλιον, gubernaculum, clavis navis; *the rudder of a ſhip.*)

Lin. gen. n. 794. *Reich. n.* 858. *Schreb. n.* 1067. *Dav. v. Royen. Rotth. in coll. hafn.* 2. 255. *Gærtn. t.* 58. *Juſſ.* 140.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Luridæ*. *Bignoniæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, ſmall, permanent: the upper ſegment very ſhort; the loweſt longer.

COR. one-petalled, ſubringent: *tube* three-cornered, with the belly flat: *border* five-cleft, wide, oblique: *ſegments* rounded; upper ones ſmaller, loweſt wider.

STAM. *Filaments* four, glandular-hairy at the baſe, ſhorter than the tube: two ſhorter than the other two. *Anthers* cordate, twin, terminated by a gland. *Rudiment* of a fifth filament between the ſhorter ſtamens, with a very ſmall anther. *Rotth.*

PIST. *Germ* conical. *Style* the length of the ſtamens. *Stigma* biſid: the upper ſegment reflex, the lower revolute. *Rotth.*

PER. *Drupe* juiceleſs, ovate-pyramidal, four-cornered, the corners thorny towards the baſe.

SEED. *Nut* covered with bony fibres variouſly interwoven, four-winged, two-celled. Nucleuſes two, oblong, covered with an aril; one lower. There is a void cell, below the fertile ones. *G.*

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* ſubringent, with a five-cleft border. *Nut* ſuberous, four-cornered, thorny at the corners, two-celled. *Seeds* two.

SPECIES.

DESCRIPTION, &c.

Stem ſimple. Leaves oppoſite, obovate, blunt, toothed, truncated, naked, with the petioles glandular on each ſide. Flowers axillary, ſolitary, ſmall. Fruit nodding[a]. According to Juſſieu, it is a trichotomous herb, with oppoſite leaves. (Burman deſcribes them as alternate, but perhaps his is a different ſpecies.) Flowers axillary, ſubſolitary. It has nearly the ſame fruit with *Trapa*; and the habit of *Martynia*. Of the ſame genus with this, or of a genus nearly allied to it is *Planta Euphraſiæ affinis. Pluk. t.* 373. *f.* 2. referred by Linneus to *Torenia*. Leaves alternate; fruit four-cornered, not thorny[a]. Thus more fully deſcribed by Gærtner—Drupe armed at the baſe of the angles with four ſpines, ſpreading out horizontally and pungent; produced at bottom into an inverſely conical peduncle, and lodged in the calyx, which is permanent, of a duſky ruſſet colour. Rind ſuberous-fungous, thin: ſhell bony, four-winged, three-celled; the two upper cells fertile, the lower one barren, ſpurious. Seeds in each cell two, ovate-oblong, attenuated upwards, ſmooth, compreſſed a little, brown, covered with a dry-membranaceous two-valved aril: valves unequal, incumbent, and covering the ſide of the ſeed outwardly, but opening on the belly with a cleft. They are faſtened on each ſide to the partition, and hang down.

This plant, whilſt it is in flower, ſmells very ſtrong of Muſk[b].

Native of the Eaſt Indies. Introduced in 1778, by Sir Joſeph Banks, Bart. It flowers in auguſt and ſeptember; and is an annual plant[c].

PEDICULARIS. (*From its ſuppoſed quality of making ſheep that feed on it louſy.*)

Lin. gen. n. 746. *Reich. n.* 804. *Schreb. n.* 1003. *Tournef. t.* 77. *Juſſ.* 101. *Gærtn. t.* 53.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ*. *Pedicularet*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, roundiſh, ventricoſe; with a five-cleft equal mouth; permanent.

COR. one-petalled, ringent: *tube* oblong, gibbous: *upper lip* galeate, erect, compreſſed, emarginate, narrower: *lower* ſpreading, flat, half-three-cleft, blunt: *middle ſegment* narrower.

STAM. *Filaments* four, the length of the upper lip, under which they lie concealed: two ſhorter. *Anthers* incumbent, roundiſh, compreſſed.

PIST. *Germ* roundiſh. *Style* filiform, in the ſame ſituation with the ſtamens, but longer. *Stigma* blunt, bent in.

PER. *Capſule* roundiſh, mucronate, oblique, two-celled, opening at top: *partition* contrary.

SEEDS ſeveral, ovate, angular. *Receptacle* ſubglobular, in the baſe of the capſule.

OBS. *Capſule oblique at top in moſt ſpecies.* Sceptrum Carolinum Rudb. *has a regular capſule, and a cloſed mouth.*
There are ſpecies that have the mouth of the calyx biſid.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Capſ.* two-celled, mucronate, oblique. *Seeds* coated.

Stem simple, leaves pinnate serrate, calyxes oblong, smooth, helmet of the corollas awl-shaped bowed longer.

DESCRIPTIONS, *&c.*

The alpine species of *Pedicularis*, that is, all, except the two first and the sixteenth, have successively occupied several of the first botanists in the present age: Linneus in Lapland, Haller in Switzerland, Gmelin in Siberia, Seguier and Allioni in Italy, and Villars in Dauphiné. Linneus has described six natives of Lapland; Haller ten of Switzerland, but he said that he had thirty species from different countries; Gmelin twelve; Allioni eleven; and Villars ten, besides several remarkable varieties. These plants have their leaves very much cut, and that in a very regular manner. Their flowers are red, white or yellow, and the mixture or shades of these three colours sometimes give the corolla the colour of fire. They grow in general at a considerable elevation, namely, more than a thousand toises above the level of the sea. Villars has taken much pains with these plants, and has corrected some mistakes into which Haller and Linneus have fallen. He observes with great modesty, that if the cedars have bent, what are we to expect of the reeds? And that he could not pass by a favourable opportunity of celebrating their memories, by showing that their mistakes were almost unavoidable, and have even been useful to us. May I not, says he, in paying homage to truth and the memory of the two first botanists of our time, hope for much indulgence from those learned men who have it in their power to correct my errors, and to complete the work which I have only begun?—Tragus affirms, and others take it from him, that these plants in pastures breed lice in animals that feed on them. The truth seems to be, that the Marsh Lousewort indicates a very bad pasture; and the want of proper food may occasion the cattle to be in bad condition, and to breed vermin[a].

[a] Villars dauph.

1. Root annual. Stem about a foot high, upright, angular, purplish, hollow, branched. Branches spreading. Leaves bipinnatifid; or pinnate with about ten pairs of long pinnas, which are semipinnate with short indented pinnules. Leaves and flowers distant. Flowers axillary, solitary, on short peduncles, forming a loose spike. Calyx two-lipped, compressed and opening sideways, reddish, a little hairy, bulging at the base; segments cloven and jagged, two of them crested or bordered with leafy appendages. Corolla purple, varying to white: helmet with a little tooth on each side, not notched at the end; lower lip fringed with fine soft hairs [a]. Capsule oblong, smooth, acuminate, involved in the calyx. Seeds numerous in each cell, ovate, bluntish, somewhat rugged, grooved [b].

Native of many parts of Europe, particularly the northern parts, in marshes and wet meadows; flowering in june and july.—It is an unwelcome guest in meadows, being disagreeable to cattle, and thought by some to be destructive to sheep: it is somewhat caustic, and seems to be seldom eaten.

2. Root annual. Stem very short. Branches from the root, long, spreading close to the ground. Leaves simply pinnate, with roundish acutely serrate pinnas. Floral leaves deeply divided: segments toothed. Leaves and flowers crowded. Flowers in a cluster at the top of the plant, and sparingly on the branches. Calyx green within, purplish without, nearly half as long as the corolla, one of the clefts much deeper; segments toothed, that opposite to the deepest cleft narrowest. Corolla purple, much more slender than the calyx: tube compressed: upper lip with a little tooth on each side; lower lip with three divisions, the middle segment a little smaller. The two taller filaments hairy towards the top [c].—Native of many parts of Europe and Siberia, in wet pastures and heaths, also in woods; flowering in june.

The expressed juice, or a decoction of this plant, has been used with advantage as an injection for sinuous ulcers. It is said that if the healthiest flock of sheep were to be fed with it, they would become scabby and scurfy in a short time, the wool would get loose, and they would be overrun with vermin [b]. This also applies to the first sort; but I doubt whether it be true of either. See what was said above.

The calyx is commonly said to be five-cleft, with one segment very small and often simple; the other four crested. To Villars it appeared to be four-cleft, like that of the preceding, from which it is distinguished by being a much smaller plant, frequently only two or three inches in height, whereas the other is sometimes eighteen inches, and in warm climates two and even three feet high: procumbent; and the flowers longer.

3. Root black, thick, having large fibres swelling out a little in the middle. Stem inclined, five or six inches high, having sometimes a lateral branch from the lower part, with one or two flowers on it; and also, but very seldom, another shorter near the base of the spike; which is rounded, and has few flowers, of a purple or deep red colour. Leaves pinnate, and their divisions toothed. Calyx a little villose: segments toothed. Upper lip of the corolla compressed and beaked [d].

Villars remarks, that this species not being always branched, to distinguish it from his *gyroflexa*, we must observe that the flowers of this are peduncled, in very small number, of a deep red, with the upper lip very much lengthened out and curved; the stem also is thinner.—Allioni informs us, that he has seen the flowers change like Linneus's *Peloria*.

Native of Switzerland, Austria, Carniola, Dauphiné, Piedmont, Silesia.

4. This is distinguished from the other species by the gape of the corolla being closed, the pericarp roundish, acuminate but regular, whereas in the others it is bent in with an oblique point; the size is half that of a man; the flowers four, five or sometimes three only at each joint, remote, in whorls, the corolla of a golden yellow colour, except that the lower lip is tinged with purple or blood red at top. Rudbeck named it *Sceptrum Carolinum* in honour of Charles XII. King of Sweden, from its manner of growth like a sceptre.—Discovered by Rudbeck in Lapland, where it was also found by Linneus, in such abundance in one place on the highway as to stop a horse going full speed. It grows also in Dalekarlia, Ostrobothnia between Kemi and Uloa, near Upsala, in Westrogothia, but more rarely [e]; Norway, in several places: Prussia and Russia: in bogs, wet woods, &c.

5. Root more simple or less branched than in the other sorts. Stems several, simple, with smooth, bipinnate leaves on them, opposite by threes or fours. Flowers red: the upper lip remote, oblong, almost straight, blunt; the lower divided into three parts. Calyx rayed, often white, membranaceous, a little coloured and puffed out after flowering. It is very small, and has beautiful red flowers. It seems to be biennial [f]. Capsule oblong, with an attenuated beak, compressed a little, membranaceous, thin, opening longitudinally by the upper edge, which is a little more convex: partition very narrow, contrary to the valves. Receptacle small, subglobular, flattened to the partition near the base. Seeds few, about ten in each cell, ovate, angular, acuminate at both ends, with a membranaceous, narrow whitish scar on one side, striated in little dots, dusky; navel beaked, curved inwards, formed of the integument, not callous [g]. Gærtner says he does not understand what Linneus means by *semina tunicata*.

Native of Switzerland, Austria, Carniola, the South of France, Silesia, Siberia.

6. Stem a foot high, even, quite simple. Leaves undivided, deeply serrate with crenulate serratures, alternate. Flowers from the upper axils solitary, sessile. Calyx even, blunt, bifid, entire. Corolla of a very deep purple, turned upside down: helmet hooked, compressed: standard wide, rounded. It varies with flesh-coloured and with milk-white flowers.—Native of Siberia [h].

7. Root perennial, woody. Stem upright, even, not more than a foot high, with few, alternate leaves, on short petioles, under the spike sessile. Root-leaves on long petioles, having about sixteen pairs of pinnas, the extreme ones confluent. Spike short, with lanceolate, acuminate, hirsute, entire, bay-coloured leaves or bractes. Calyx five-cleft, villose, as are also the bractes. Corolla purple or bay-rose-colour. Helmet sickle-shaped, hooked, cut off at top. Pistil and stamens stand out far beyond the helmet [i].

Native of Switzerland, Austria and Silesia. Introduced in 1787, by William Pitcairn, M. D.

8. This is a very hairy plant. Stem quite simple, a span high. Leaves alternate, pinnatifid, serrulate. Flowers heaped into a spike or head. Corolla blunt, yellow; with the helmet a little curved inwards, villose at the edge [k]. Gmelin says that the flowers are collected into a very close spike, that the corolla is of a very pale yellow, and that the beak is blunt.—Native of Siberia.

9. This at first sight resembles *Sceptrum Carolinum* in miniature, but it is twenty times less. It differs from the other species in having the leaves very like those of *Filipendula*, with the segments imbricate; the root tuberous and fusiform, like Skirrets, with a few scales at the base; the corolla tawny, with the top of the upper lip purple, the lower lip, shorter by half than the upper.—Stem scarcely a finger's length, round, upright, dark purple. Root-leaves very many, spreading, on filiform petioles, bluntly lanceolate, almost divided to the midrib; the divisions ovate, the edge of one lying over the next, crenate and each notch crenulate. Stem-leaves fewer, some immediately under the spike, like the root-leaves. Spike terminating the stem, and covering a third part of it, upright, compressed, oblong. Calyx striated, thin, four-toothed, oblong. Corolla narrow, the lower lip very small, the upper narrow, almost upright, blunt. Pericarp acuminate, with the tip curved inwards [l]. The calyxes

[a] Withering, Lightf. [b] Pollich. [c] Withering, Lightf. [d] Withering. [e] Villars. [f] Villars. [g] Gærtner. [h] Linn. spec. [i] Krocker. [k] Linn. Iapp. & fuec. [l] Linn. Iapp.

are

are by no means ferrate; and the corolla is very dark purple, eſpecially at the end [a]. Haller ſays that the upper petal or helmet is ferruginous; the lower or beard pale yellow.

Native of Lapland, Switzerland, Sileſia, Siberia.—Introduced in 1775, by Drs. Pitcairn and Fothergill [b].

10. Root perennial. Stem half a finger's length, thick, with oblong cluſtered ſcales at the baſe. Root-leaves almoſt linear ſcales. Stem-leaves a little longer than the ſcales, crenate at the end, the upper ones linear-lanceolate, tooth-pinnate beyond the middle, the reſt flat, broad, ariſing from a wide petiole, and embracing: the toothlets very narrow and very minutely crenated. Spike terminating, very ſhort, but thick and quadrangular: flowers ſix to twelve, ſeſſile: calyxes large, ovate, four-cleft beyond the middle, acute, aſh-coloured; the lower lip ſhorter, the upper upright blunt; pale fleſh-colour, with a deeper heart-ſhaped ſpot on the lower lip. It differs from the reſt in its wide embracing petioles, villoſe calyxes, the colour of the corolla, and the notches of the leaves [c].

Villars can ſcarcely think that the little Lapland plant is the ſame with that of Dauphiné and Piedmont. He deſcribes it to be only two or three inches high, with the ſtem and leaves ſmooth. Leaves bi-pinnate, very fine and flat: on the ſtem only one or two, pinnate. Flowers from five to ſeven, in a diſtinct ſpike. Calyx in five ſimple diviſions, very villoſe. Upper lip of the corolla blunt, a little curved: the whole bright red. It is allied to *P. incarnata*, but is only one ſixth of the ſize. Monſ. Villars found a plant at the Grande Chartreuſe, connecting theſe two, in the ſize, and the form of the leaves, but the calyx leſs villoſe than either.—Native of Lapland, Dauphiné, Piedmont, Siberia.

11. Root branched, yelloviſh white. Stems one, two or three, riſing amid abundance of root-leaves, not much ſhorter than the ſtems, and having the appearance of lanceolate bipinnate fronds. Pinnas very narrow, linear, pinnatifid-toothletted, ſeſſile, flat, decreaſing in ſize both ways, naked, deep green above, watery green underneath; the rachis firſt green, then red, and finally dark purple. On the ſtem one, or at moſt two leaves, like the others only much leſs. Stem upright, ſomewhat angular, changing colour like the rachis, ſmooth and ſhining, towards the ſpike, eſpecially when young, white-villoſe. Spike terminating, ſhort, compact; each flower riſes on a ſhort red pedicel from the axil of a leafy bractle, almoſt exceeding the calyx, green, pinnatifid-toothed; but in the upper bractles the teeth decreaſe to two and even one. Calyx from an ovate baſe tubularly cylindrical, five-toothed: teeth equal, ſimple, acute, red, as are alſo the nerves of the tube: the reſt of the calyx is green, but the villoſe hairs that cover it are white and tranſparent. Corolla elegant, red; with a tube longer than the calyx, fading away from red to white: helmet deep red, very blunt, ſtraight, compreſſed, half cloſed, bifid below the tip: lower lip three-lobed; lobes rounded, the middle one ſomewhat ſhorter, all entire. Anthers in front preſſed cloſe to each other, with the lateral edges white-villoſe, the villoſe hairs prominent beyond the helmet. Style roſe-coloured at top, with a bluntiſh yelloviſh ſtigma.—Native of Carinthia; flowering in July [d].

12. Stem from a foot to eighteen inches in height, upright, not branched, terminating in a very long ſpike. Midrib of the leaves wide; pinnas ſemipinnate, ſharply toothed. Spike when young cloſe, afterwards looſe, with ſmall bractles. Calyx half-five-cleft, with unequal ſegments, the lower longeſt, bearded with much cottony down. Helmet narrow, beaked. Corolla purple. Lower lip almoſt equally three-lobed, the middle lobe ſomewhat ſmaller [e].

This plant ſeldom has more than one ſtem from a root. Leaves large, bipinnate, thick and ſolid, ſmooth or very little villoſe; they are better furniſhed, and the diviſions are thicker and much leſs deeply cut than in *P. tomoſa* and *foliоſa*. Flowers many, red, in a long, looſe ſpike. Calyx villoſe, and its diviſions ſimple. Upper lip of the corolla falcated to form a pendant hook like a truncated beak, at the end of which appears the ſtigma. There is one variety, which is ſmaller and ſmooth: and another, with the leaves leſs cut and almoſt ſimple, the ſtem lower, and the flowers fewer, the colour of fire inclining more or leſs to yellow [f].

There is no doubt of this being the plant of Allioni and Haller; but Villars heſitates reſpecting Linnæus, who deſcribes the calyx as ſmooth.

Native of Switzerland, Auſtria, Dauphiné, Sileſia, Siberia.

13. Root perennial. Stem a ſpan high, upright, almoſt ſtraight, round, ſmooth. Root-leaves ſcarcely any. Stem-leaves ſeven or eight, lanceolate, acute, narrowed at the baſe into the petiole, alternate, divided to the middle into from fourteen to twenty pinnas, each having from two to five toothlets on each ſide, ſmooth. Spike terminating, looſe, four-cornered, compoſed of from ſix to ſixteen flowers, declining from the perpendicular, each furniſhed with its bractle; the lower bractles longer than the flowers, the upper ones ſcarcely ſo long as the calyx. Calyx ſmooth, tubular, with a bifid blunt mouth. Corolla yellow, with the upper lip compreſſed, produced at the tip, reflexed downwards, and prominent, like an eagle's beak [g].

In Flora Suecica it is deſcribed as a palm in height; all the leaves of the ſame ſize, and not the root-leaves larger; pinnatifid, ferrate; calyxes ſometimes quite entire, ſometimes with two or four teeth. It differs from *P. tuberoſa* in being ſmaller, in having more leaves on the ſtalk, ſmaller flowers, the root-leaves the ſame with thoſe of the ſtem, the pinnas not ſubdivided but merely ferrate, the calyxes not ferrate, but, excepting three or four teeth, quite entire at the edge, and the ſtems ſmooth not hirſute.

Native of the mountains of Lapland and Dalecarlia, Denmark and Siberia.

14. Calyx five-toothed, tubular, quite entire, a little hairy. Corolla yellow, with the upper lip ſharp but emarginate, the two teeth ſharp and nodding [h].

By its port, ſize and diſpoſition of the flowers it holds the place between *P. tuberoſa* and *foliоſa*. Lateral roots whitiſh, tuberous, thicker at the end, as repreſented in John Bauhin's figure (3. 438.); the middle root is bigger and blackiſh. Stems commonly two, a foot high. Root-leaves tripinnate, the laſt diviſions terminating in a white thread or ſpine a quarter or a third of a line in length. Stem-leaves two or three, ſmaller, and with the leaflets fewer and more ſeparated. Spike terminating, three or four inches long, with white or yellow flowers, ſeparated by bractles, which lengthen on their axis, and appear little beyond the flower though they are longer: helmet bent back like a ſickle, compreſſed, ending in a narrow but truncated point: they are inclined or roll round to the left, as in *P. roſtrata* and *gyroflexa* [i].

Native of the mountains of Italy, Dauphiné and Siberia.—Introduced in 1775, by the Doctors Pitcairn and Fothergill [k].

15. Leaves bipinnatifid. Calyxes with the angles and edge hairy. Corolla pale yellow: helmet not beaked, very blunt, hooked. Stem frequently a foot high [l].

This is loftier and ſtronger than moſt of the other ſpecies. Root ſimple, biennial. Stem from a foot to eighteen inches in height, ſtrong and thick, loſing the root-leaves, as ſoon as it riſes to flower. Leaves very large, tripinnate, with the diviſions very narrow, diſtinct and ſharp, without ſenſible points. Stem-leaves two or three, ſmaller and at the upper part only. The flowers form a conſiderable ſpike, are of a yellow colour, and ſeparated by large bipinnate leaves [m].

Gouan remarks, that this is very different from the other ſpecies, even when it is not in flower. For the root-leaves are pinnate, with the pinnas deeply pinnatifid, and the lobules ſharply toothed: the ſtem-leaves on the other hand, eſpecially the upper ones

[a] Lin. ſuec. & ſyſt. [b] Hort. kew. [c] Linn. lapp. [d] Jacqu. miſc. [e] Haller. [f] Villars. [g] Linn. lapp. [h] Lin. ſpec. [i] Villars. [k] Hort. kew. [l] Linn. [m] Villars.

are

are decurſively pinnate, the pinnas being confluent as in Tanſey, Achillea, &c. Petioles, at leaſt the young ones hoary and very hirſute: Helmet of the corolla blunt and villoſe as in *Phlomis Leonurus*. Haller's figure is good as to the calyx, ſpike and root-leaves; but the ſtem-leaves are very ill repreſented: but Gouan refers to *ſ.* 1. as Haller himſelf does.

Native of Switzerland, Auſtria and the South of France.—Introduced in 1786, by Edmund Davall, Eſq.[r]

16. Root perennial. Stem upright, a ſpan high, pubeſcent towards the top. Leaves alternate, pinnatifid, gaſhed, crenate, blunt, ſmooth. Spike terminating, ſeſſile, ovate, with leaflets a little longer than the calyx. Calyxes pubeſcent, truncated obliquely downwards. Corollas white: helmet ſomewhat ſickle-ſhaped, ſcarcely beaked, but in a manner cut off at the tip, with a tooth ſcarcely apparent at the upper edge, and a briſtly tooth on each ſide at the lower edge, much more lengthened out than that in *P. ſylvatica* and *tuberoſa*. Lower lip trifid, blunt.—Found by Kalm in North America[s].

17. Leaves like thoſe of *Achillea Millefolium* or Milfoil. Leaves and calyxes lanuginous. Corollas yellow[h].

Villars deſcribes a plant under this name of *P. tuberoſa*, which is ſo nearly allied to *P. comoſa*, that it may poſſibly be no more than a variety of it.—Root thick and a little tuberous, black, fibrous and thick. Stem ſimple, villoſe, and very thick. Height from eight inches to a foot. Leaves villoſe, almoſt tripinnate, the diviſions diſtinct, reſembling a ſmall fern: each laſt diviſion ends in a very ſhort, recurved, whitiſh thread. The ſtem has only a leaf or two: The flowers form a very thick ſpike, cloſer at top than at bottom: they are yellow or whitiſh. The leaves among the flowers and the diviſions of the calyx are both ſimple. (According to Allioni (*ſpec.* 50. *t.* 11. *f.* 1. they are divided.) The upper lip of the corolla is ſickle-ſhaped, and pointed at the end.—See the next ſpecies.

Haller deſcribes his n. 323. thus—Root compoſed of numerous round bulbs or tubers, almoſt woody, collected into one head. Root-leaves very numerous, long, pinnate, with twenty pairs of pinnas, ſemipinnate, pinnules having one or two teeth. Stems not branched, a long ſpan or a foot in height, hirſute, almoſt leafleſs, or having at moſt one or two pairs of leaves. Flowers in a cloſe ſpike, ſeparated by leaves, ſcarcely ſtanding out beyond the calyx. Fruit conical, compreſſed, imperfectly two-celled, with the partition ſhorter than the horn. Colour of the flowers very pale yellow. Helmet acutely beaked.

According to Linneus, it is a native of the Swiſs, Italian and Siberian mountains. But Villars doubts the exiſtence of it, and refers the *tuberoſa* of Linneus, Allioni and Scopoli to his *gyroflexa*.

18. Root perennial, compoſed of a dark black trunk, often carious, three or four lines in diameter, from which ſpring thick lateral fibres, horizontal, quite ſimple, pretty long, not at all ſwelling out, any more than the trunk of the root. Stems one, two, ſometimes ſeveral, riſe bending to the height of ſix or eight inches, ſeldom a foot; they are villoſe, firm, and have one or two bipinnate leaves at their baſe, and as many, but ſmaller, on the upper part; they are terminated by a ſpike of a beautiful red colour, truncated and villoſe, compoſed of pinnatifid bractes of ſeveral villoſe calyxes, the diviſions of which are toothed or pinnatifid. Helmet of the corolla turned to the left, pointed: the lower lip has three rounded diviſions, concealed one under the others. Root-leaves long, bipinnate; leaflets tooted; diviſions blunt, villoſe, frequently recurved upwards, hard and as it were dried, having often a white mealy border; they are all petioled, well furniſhed, and a little imbricate. Capſule oval, pointed, a little villoſe, containing whitiſh ſeeds.

There is a variety, with finer and more diſtinct leaves, a yellow flower, and the piſtil longer than the corolla, which according to Bellardi is the *tuberoſa* of Linneus.

It ſeems that Scheuchzer, adopting Tournefort's ſynonym of *P. alpina aſphodeli radice, purpuraſcente flore*, which is certainly not this plant, has deſcribed this ſpecies under John Bauhin's name of *P. bulboſa* (3. 438.), though the latter has figured and deſcribed *P. comoſa* under this name, and that never has a red flower. This miſtake of Scheuchzer, occaſioned perhaps by the vague obſervations of Cluſius, who mentions one ſpecies with a purple, and another with a yellow flower, has given riſe to ſeveral others. 1. Haller and Moriſon have found it difficult to reconcile theſe differences of colour in a genus where they are ſufficiently conſtant; and the former complains that Tournefort and Magnol have aſſigned a red colour to the flowers of theſe plants. 2. Haller at firſt deſcribed and gave the ſynonym of *P. bulboſa*, J. B. which is *P. comoſa*, Linn.; but his figure, which is the ſame in both editions, cannot agree with it, on account of the toothed calyx; and approaches nearer to *P. gyroflexa*, which Haller has under n. 324. 3. Linneus (*ſpec. ed.* 1. 610.) having given a *P. tuberoſa*, with the diviſions of the calyx toothed like a cock's comb, and that doubtleſs after the figure of Haller, without conſulting the deſcriptions; an apocryphal ſpecies has been produced, which has occaſioned a diſagreement even among the beſt informed botaniſts. Scopoli and Allioni have given the name of *P. tuberoſa* to our *P. gyroflexa*: the latter, and others have ſent it under this name to Juſſieu; whilſt Gmelin, Chaix and Seguier, conſulting John Bauhin, and the deſcriptions of Haller, have given the name of *P. tuberoſa* to the *comoſa* of Linneus, which deſerves that name better on account of its roots[t].

Native of the South of France, Switzerland, Carniola, Piedmont.

19. Native of Greenland. Firſt given by Retzius under the name of *P. incarnata*, from which it differs in the leaves, ſpike, calyx, and helmet of the corolla[x].

Miller mentions four kinds of Louſewort, without any names, but he inſiſts chiefly on the Yellow Rattle, which is *Rhinanthus Criſta galli*.

DESCRIPTION, *&c.*

1. Root as large as a man's little finger, by age becoming woody. The ſtalks decay every autumn, and new ones ariſe in the ſpring: they grow about a foot long, and divide into ſeveral ſmall branches. Leaves thick, oblong, cut into ſeveral narrow ſegments, dark green, gummy and of a bitteriſh taſte. The flowers are produced at the ends of the branches, ſitting cloſe between the leaves. Corolla white. [Capſule ſlightly umbilicated at top, three-grooved: partitions faſtened to the middle of the valves, anſwering to the grooves on the outſide. Seeds oblong, awl-ſhaped or angular, attenuated towards the navel, brown-bay, netted with very minute excavations, faſtened in a horizontal poſition to the central thickened edge of the partitions[1].
Native of Spain, in the county of Nice, Syria, Cappadocia, Galatia, Siberia.—It was cultivated here in 1570, as appears from Lovel, *adv.* 390.[2]] It flowers in july, and in warm ſummers the ſeeds will ripen here in the autumn.
[Willich remarks, that the calyx ſhould rather be conſidered as a floral leaf; for it has the ſame ſtructure with the leaves, and is perfect and expanded long before the opening of the flower: and that the ſtigma is curved in, twiſted and ſtraight, all on the ſame plant.
2. Native of Siberia.
Retzius and Vahl have each another ſpecies.]

PROPAGATION AND CULTURE.

They are propagated by ſeeds, ſown thinly on a bed of light earth, the beginning of april: when the plants come up, keep them clean from weeds: at the end of october or beginning of november, when the ſtalks decay, cover the bed with tanner's bark, aſhes or ſaw-duſt, to keep out the froſt, for the roots are ſomewhat tender when young. In march following tranſplant them into a warm ſituation and dry ſoil, where they will continue ſeveral years.

Gerania africana. *Linn.*
Claſſ. 16. 3. Monadelphia Heptandria.
Nat. order of *Gruinales. Gerania*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted: *ſegments* ovate, acute, concave, permanent; upper ſegment, ending in a capillary nectariferous tube, decurrent along the peduncle.
COR. *Petals* five, obcordate or ovate, ſpreading, large, irregular.
STAM. *Filaments* ten, awl-ſhaped, united at the baſe, ſpreading at top, unequal in length, all ſhorter than the corolla, three of them (ſeldom five) caſtrated. *Anthers* ſeven, oblong, verſatile.
PIST. *Germ* five-cornered, beaked. *Style* awl-ſhaped, longer than the ſtamens, permanent. *Stigmas* five, reflex.

PER. *Capſule* five-grained, beaked, the cells opening inwards, the beak ſpiral, bearded on the inſide.
SEEDS ſolitary, ovate-oblong.

ESSENTIAL CHARACTER.

Cal. five-parted, the upper ſegment ending in a capillary nectariferous tube running along the peduncle. *Cor.* five-petalled, irregular. *Filam.* ten, unequal, three of which (ſeldom five) are caſtrated. *Fruit* five-grained, beaked: beak ſpiral, bearded within.

Ait. hort. kew. 2. 420. *L'Herit. n.* 31.

Umbels many-flowered, flowers in a ſort of head, leaves cordate-roundiſh obſoletely lobed, ſtem three-ſided-angular.

12. Pelargonium althæoides. *Althæa-leaved Crane's-bill.*

Ait. hort. kew. 2. 420. *L'Herit. n.* 39 *t.* 10.]

G. althæoides. *Lin. ſpec.* 949. *ſyſt.* 615. *Reich.* 2. 314. *mant.* 433. *hort. cliff.* 345. *Burm. ger.* 54. *Mill. dict. n.* 43. *Boerh. lugdb.* 1. 263.

Peduncles many-flowered, leaves cordate-ovate ſinuate toothed, the uppermoſt pinnatifid, petals equal to the calyx.

[13. Pelargonium ſenecioides. *Small white-flowered Crane's-bill.*

Ait. hort. kew. 2. 420. *L'Herit. n.* 42. *t.* 11.

Peduncles three-flowered, involucres and calyxes blunt, leaves bipinnatifid-laciniate, ſtem herbaceous.

14. Pelargonium coriandrifolium. *Coriander-leaved Crane's-bill.*

Ait. hort. kew. 2. 421. *L'Herit. n.* 43. *Jacqu. ic. rar.* 528. *collect. ſuppl.* 142.]

Geranium coriandrifolium. *Lin. ſpec.* 949. *Reich.* 3. 315. *mant.* 433. *Cavan. diſſ.* 263. *n.* 390. *t.* 116. *f.* 1. *Mill. dict. n.* 40. *Riv. pent. t.* 108. *Herm. lugdb.* 279. *t.* 280.

β. P. caucalifolium. *Jacqu. ic.* 529. *collect. ſuppl.* 145.

Peduncles ſubtriflorous, corollas ſubtetrapetalous, leaves bipinnate linear, ſtem herbaceous ſmoothiſh.

15. Pelargonium myrrhifolium. *Myrrh-leaved Crane's-bill.*

Ait. hort. kew. 2. 421. *L'Herit. n.* 44.

G. myrrhifolium. *Lin. ſpec.* 949. *ſyſt.* 615. *Reich.* 3. 315. *mant.* 433. *Berg. cap.* 178. *Mill. dict. n.* 36. *Herm. lugdb.* 279. *t.* 281. *Riv. pent.* 102?

Peduncle ſubtriflorous, corollas ſubtetrapetalous, leaves bipinnatifid, the lower ones cordate lobed, ſtem ſomewhat ſtrigoſe.

§. 4. *Shrubby, with a fleſhy or thick ſtem.*

[16. Pelargonium tenuifolium. *Fine-leaved Crane's-bill.*

Ait. hort. kew. 2. 421. *L'Herit. n.* 48. *t.* 12.

Umbels many-flowered, leaves decompoundedly pinnate multifid linear hirſute, ſtem fleſhy, flowering-branches ſlender.

17. Pelargonium carnoſum. *Fleſhy-ſtalked Crane's-bill.*

Ait. hort. kew. 2. 421. *L'Herit. n.* 49.]

G. carnoſum. *Lin. ſpec.* 946. *Reich.* 3. 310. *amoen.* 4. 281. *Burm. ger.* 51. *Mill. dict. n.* 29. *Dill. elth.* 153. *t.* 127. *f.* 154.

Umbels many-flowered, leaves pinnatifid laciniate, petals linear, joints fleſhy-gibboſe.

[18. Pelargonium ceratophyllum. *Horn-leaved Crane's-bill.*

Ait. hort. kew. 2. 422. *L'Herit. n.* 50. *t.* 13. *Curt. magaz.* 315.

Umbels many-flowered, leaves remotely pinnate fleſhy round, ſegments channelled obſoletely trifid.

19. Pelargonium crithmifolium *Sampire-leaved Crane's-bill.*

Smith ic. rar. 13.

Umbels many-flowered panicled, leaves bipinnate fleſhy dilated and jagged at the tips, petals obtuſe, the upper ones criſped at the baſe.

20. Pelargonium gibboſum. *Gouty Crane's-bill.*

Ait. hort. kew. 2. 422. *L'Herit. n.* 51.]

Geranium gibboſum. *Lin. ſpec.* 946. *ſyſt.* 613. *Reich.* 3. 311. *hort. upſ.* 345. *Mill. dict. n.* 30. *Knipb. cent.* 8. *n.* 46.

G. foliis aquilegiæ. *Riv. pent.* 100. *Herm. lugdb.* 284. *t.* 285. *Stiff. bot. t.* 111. *Burm. aſr. t.* 37. *f.* 2. *p.* 96.

Umbels many-flowered, leaves pinnate-pinnatifid-confluent at the tip, joints fleſhy gibboſe.

21. Pelargonium fulgidum. *Celandine-leaved Crane's-bill.*

Ait. hort. kew. 2. 422. *L'Herit. n.* 53.

Geranium fulgidum. *Lin. ſpec.* 945. *Reich.* 3. 307. *vir. cliff.* 67. *hort. cliff.* 498. *Burm. ger.* 52. *Mill. dict. n.* 31. *Dill. elth.* 156. *t.* 130. *f.* 157. *Till. piſ.* 68. *t.* 26.

Umbel twin, leaves three-parted, pinnatifid-gaſhed, middle ſegment very large.

[22. Pelargonium quercifolium. *Great Oak-leaved Crane's-bill.*

Ait. hort. kew. 2. 422. *L'Herit. n.* 54. *t.* 14.

Geranium quercifolium. *Linn. ſuppl.* 306. *ſyſt.* 619. *Cavan. diſſ.* 4. 246. *t.* 119 *f.* 1.

G. terebinthinaceum. *Murr. in comm. gott.* 7. (1785.) 88. *t.* 4.

β. P. quercif. pinnatifidum. *L'Herit. t.* 15. *Small Oak-leaved Crane's-bill.*

Umbels ſubmultiflorous, leaves cordate pinnatifid crenate, ſinuſes rounded, filaments aſcending at the tip.

23. Pelargonium Radula. *Multifid-leaved Crane's-bill.*

Ait. hort. kew. 2. 423. *L'Herit. n.* 55. *t.* 16.

Geranium Radula. *Cavan. diſſ.* 4. 262. *t.* 101. *f.* 1. *Curt. magaz. t.* 95.

G. revolutum. *Jacqu. ic.* 3. *t.* 133. *collect.* 1. 84.

Umbels few-flowered, leaves pinnatifid-laciniate rugged revolute, ſegments linear.

24. Pelargonium graveolens. *Strong ſcented Crane's-bill.*

Ait. hort. kew. 2. 423. *L'Herit. n.* 56. *t.* 17.

Geranium terebinthinaceum. *Cavan. diſſ.* 4. 250. *t.* 114. *f.* 1.

Umbels many-flowered ſubcapitate leaves palmate ſeven-lobed, ſegments oblong blunt crenulate at the edge.

25. Pelargonium papilionaceum. *Butterfly Crane's-bill.*

Ait. hort. kew 2. 423. *L'Herit. n.* 58.]

Geranium papilionaceum. *Lin. ſpec.* 945. *ſyſt.* 613. *Reich.* 3. 308. *hort. cliff.* 345. *upſ.* 197. *Burm. ger.* 49. *Mill. dict. n.* 27. *Knipb. cent.* 7. *n.* 27. *Dill. elth.* 124. *t.* 128. *f.* 155. *Mart. cent. t.* 15.

Umbels many-flowered, leaves roundiſh-cordate angular. corollas papilionaceous, wings and keel minute.

26. Pelargonium inquinans. *Scarlet-flowered Crane's-bill.*

Ait. hort. kew. 2. 425. *L'Herit. n.* 59.

Geranium inquinans. *Lin. ſpec.* 945. *ſyſt.* 613. *Reich.* 3. 307. *hort. upſ.* 195. *cliff.* 345. *Burm. ger. n.* 46. *Mill. dict. n.* 24. *Mill. illuſtr. Knipb. cent.* 3. *n.* 42. *Knorr. del.* 1. *t.* S. 19. *a. Dill. elth.* 151. *t.* 125. *f.* 151. *Mart. cent. t.* 3.

Umbels many-flowered, leaves orbiculate-reniform ſcarcely divided crenate tomentoſe and clammy.

[27. Pelargonium hybridum. *Baſtard Crane's-bill.*

Ait. hort. kew. 2. 424. *L'Herit. n.* 60.

Geranium hybridum. *Lin. mant.* 97. *ſyſt.* 613. *Reich.* 3. 308. *Dill. elth.* 152. *t.* 125. *f.* 152.

Umbels many-flowered, leaves obovate crenate ſmooth fleſhy, petals linear.

28. Pelargonium zonale. *Common Horſe-ſhoe Crane's-bill.*

Ait. hort. kew. 2. 424. *L'Herit. n.* 61.]

Geranium zonale. *Lin. ſpec.* 947. *ſyſt.* 613. *Reich.* 3. 311. *hort. upſ.* 196. *Burm. ger. n.* 43. *Mill. dict. n.* 23. *Comm. prael.* 51. *t.* 1.

Umbels many-flowered, leaves cordate-orbiculate ſcarcely lobed toothed zoned.

[29. Pelargonium heterogamum. *Red-flowered Crane's-bill.*

Ait. hort. kew. 2. 424. *L'Herit. n.* 62. *t.* 18.

*Umbels many-flowered, leaves ſubarbiculate, gaſh-lobed * toothed, ſtem erect ſhrubby.*

30. Pelargonium monſtrum. *Cluſter-leaved Crane's-bill. Ait. hort. kew.* 2. 425. *L'Herit. n.* 63.

Leaves orbiculate-reniform obſoletely lobed complicated curled.

31. Pelargonium bicolor. *Two-coloured Crane's-bill. Ait. hort. kew.* 2. 425. *L'Herit. n.* 64. *Curt. magaz.* 201.

Geranium bicolor. *Lin. ſyſt.* 614. *Jacqu. hort.* 3. 23. *t.* 39. *Cavan. diſſ.* 4. 248. *t.* 111. *f.* 1.

Umbels many-flowered, leaves ternatiſid lobed toothed waved villoſe.

32. Pelargonium vitifolium. *Balm-ſcented Crane's-bill. Ait. hort. kew.* 2. 425. *L'Herit. n.* 65.]

Geranium vitifolium. *Lin. ſpec.* 947. *Reich.* 3. 311. *hort. upſ.* 196. *Burm. ger. n.* 40. *Mill. dict. n.* 26. *Dill. elth.* 152. *t.* 126. *f.* 153.

β. G. vitifolium quinquelobum. *L'Herit. t.* 19.

Flowers in heads, leaves cordate three-lobed ſomewhat rugged, ſtems upright.

33. Pelargonium capitatum. *Roſe-ſcented Crane's-bill. Ait. hort. kew.* 2. 425. *L'Herit. n.* 66.

Geranium capitatum. *Lin. ſpec.* 947. *ſyſt.* 614. *Reich.* 3. 312. *hort. upſ.* 196. *cliff.* 345. *Burm. ger.* 41. *Mill. dict. n.* 25. *Knipb. cent.* 9. *n.* 41. *Herm. lugdb.* 277. *t.* 278. *Riv. pent.* 99.

Flowers in heads, leaves cordate lobed waved ſoft, ſtems diffuſed.

[34. Pelargonium glutinoſum. *Clammy Crane's-bill. Ait. hort. kew.* 2. 426. *L'Herit. n.* 67. *t.* 20. *Curt. magaz.* 143.

Geranium glutinoſum. *Jacqu. ic.* 1. *t.* 131. *collect.* 1. 85.

G. viſcoſum. *Cavan. diſſ.* 4. 246. *t.* 108. *f.* 2. *Scop. inſubr.* 2. 27. *t.* 14.

Umbels few-flowered, leaves cordate haſtate-quinquangular clammy.]

35. Pelargonium cucullatum. *Hooded Crane's-bill. Ait. hort. kew.* 2. 426. *L'Herit. n.* 68.

Geranium cucullatum. *Lin. ſpec.* 946. *ſyſt.* 613. *Reich.* 3. 310. *mant.* 432. *hort. cliff.* 345. *upſ.* 196. *Burm. ger.* 42. *Berg. cap.* 174. *Mill. dict. n.* 21. *Herm. lugdb.* 274. *t.* 275. *Seba muſ.* 1. *t.* 26. *f.* 2. *Riv. pent.* 98. *Knipb. cent.* 7. *t.* 27.

Umbels ſubmultiflorous, leaves kidney-form cowled toothed.

36. Pelargonium anguloſum. *Marſh-mallow-leaved Crane's-bill. Ait. hort. kew.* 2. 426. *L'Herit. n.* 69.

Geranium anguloſum. *Mill. dict. n.* 22. *Dill. elth.* 155. *t.* 129. *f.* 156. *Mart. dec.* 3. *t.* 28.

G. acerifolium. *Cavan. diſſ.* 4. 243. *t.* 112. *f.* 2.

Umbels many-flowered, leaves rounded cowled angular toothed.

[37. Pelargonium acerifolium. *Maple-leaved Crane's-bill. Ait. hort. kew.* 2. 427. *L'Herit. n.* 70. *t.* 21.

Umbels five-flowered or thereabouts, leaves palmate-five-lobed ſerrate wedge-ſhaped at bottom undivided.

38. Pelargonium cordatum. *Heart leaved Crane's-bill. Ait. hort. kew.* 2. 427. *L'Herit. n.* 71. *t.* 22.

P. cordifolium. *Curt. magaz.* 165.

Geranium cordifolium. *Cavan. diſſ.* 4. 240. *t.* 117. *f.* 3.

α. Leaves undivided very ſoft flat.

β. *Cut-leaved heart-leaved Crane's-bill.*

Leaves laciniated curled.

Umbels many-flowered, leaves cordate acute toothed, lower petals linear acute.

39. Pelargonium echinatum. *Prickly-ſtalked Crane's-bill. Curt. magaz.* 309.

Stem fleſhy, ſtipules ſpineſcent, leaves cordate-roundiſh from three to five-lobed, flowers umbelled, umbels ſeven or eight-flowered.

40. Pelargonium tetragonum. *Square ſtalked Crane's-bill. Ait. hort. kew.* 2. 427. *L'Herit. n.* 72. *t.* 23. *Curt. magaz.* 136.

Geranium tetragonum. *Linn. ſuppl.* 305. *ſyſt.* 619. *Jacqu. ic.* 1. *t.* 132. *collect.* 1. 92. *Scop. inſubr.* 1. 12. *t.* 5. (trigonum). *Cavan. diſſ.* 4. 231. *t.* 99. *f.* 2.

Peduncles two-flowered, branches four-cornered fleſhy, corollas four-petalled.

41. Pelargonium peltatum. *Peltated Crane's-bill. Ait. hort. kew.* 2. 427. *L'Herit. n.* 73.]

Geranium peltatum. *Lin. ſpec.* 947. *ſyſt.* 613. *Reich.* 3. 311. *hort. cliff.* 345. *Burm. ger.* 48. *Mill. dict. n.* 32. *fig. t.* 140. *Knipb. cent.* 6. *n.* 43. *Comm. præl.* 52. *t.* 2. *Curt. magaz.* 20. *Raii hiſt.* 3. 514. *n.* 38.

Umbels few-flowered, leaves five-lobed quite entire fleſhy peltated, branches angular.

[42. Pelargonium lateripes. *Ivy-leaved Crane's-bill. Ait. hort. kew.* 2. 428. *L'Herit. n.* 74. *t.* 24.

Umbels many-flowered, leaves cordate five-lobed ſomewhat toothed fleſhy, branches round.

43. Pelargonium cortuſæfolium. *Cortuſa-leaved Crane's-bill.*

Ait. hort. kew. 2. 428. *L'Herit. n.* 75. *t.* 25. *Jacqu. ic.* 539. *collect. ſuppl.* 134.

Umbels many-flowered, leaves cordate gaſh-lobed waved bluntly toothed, ſtipules awl-ſhaped.

44. Pelargonium craſſicaule. *Thick-ſtalked Crane's-bill. Ait. hort. kew.* 2. 428. *L'Herit. n.* 77. *t.* 26.

Umbels many-flowered, leaves kidney-form obcuminate, ſtem fleſhy branched even.

45. Pelargonium cotyledonis. *Hollyhock-leaved Crane's-bill.*

Ait. hort. kew. 2. 428. *L'Herit. n.* 81. *t.* 27.

Geranium cotyledonis. *Linn. mant.* 569. *ſyſt.* 614. *Reich.* 3. 313.

Umbels compound, leaves cordate peltate wrinkled, ſtem fleſhy.

§. 5. *Shrubby, with a woody ſtem.*

46. Pelargonium ovale. *Oval-leaved Crane's-bill. Ait. hort. kew.* 2. 429. *L'Herit. n.* 83. *t.* 28.

P. Oenotheræ. *Jacqu. ic. rar.* 525.

Geranium ovale. *Burm. cap.* 19.

G. ovatum. *Cavan. diſſ.* 4. 238. *t.* 103. *f.* 3. *Jacqu. collect.* 2. 355.

Umbels few-flowered, pedicels elongated, leaves elliptic toothed, ſtems biſpute.

47. Pelargonium betulinum. *Birch-leaved Crane's-bill. Ait. hort. kew.* 2. 429. *L'Herit. n.* 84. *Curt. magaz.* 148.]

Geranium betulinum. *Lin. ſpec.* 946. *ſyſt.* 613. *Reich.* 3. 309. *Burm. ger. n.* 38. *Berg. cap.* 175. *Mill. diſſ. n.* 43. *Burm. afr.* 86, 87. *t.* 33. *f.* 1, 2. *Raii ſuppl.* 513. 22. *Pluk. mant.* 1. 415. *f.* 3.

Umbels few-flowered, leaves ovate unequally ſerrate lobe-gated.

[48 Pelargonium glaucum. *Spear-leaved Crane's-bill. Ait. hort. kew.* 2. 429. *L'Herit. n.* 89. *t.* 29.

Geranium glaucum. *Linn. ſuppl.* 306. *ſyſt.* 614.

G. lanceolatum. *Cavan. diſſ.* 4. 235. *t.* 102. *f.* 2. *Curt. magaz.* 56.

Pedunc'es two-flowered, leaves lanceolate quite entire acuminate glaucous.

49. Pelargonium tricuſpidatum. *Three-pointed Crane's-bill. Ait. hort. kew.* 2. 430. *L'Herit. n.* 90. *t.* 30. *Jacqu. collect. ſuppl.* 139.

Peduncles two-flowered, leaves three-pointed, middle lobe more produced ſubſerrate, midrib muricated underneath.

50. Pelargonium acetoſum. *Sorrel Crane's bill. Ait. hort. kew.* 2. 430. *L'Herit. n.* 97. *Curt. magaz.* 103.]

Geranium acetoſum. *Lin. ſpec.* 947. *Reich.* 3. 308. *hort. cliff.* 345. *Burm. ger.* 47. *Mill. dict. n.* 28. *Knipb. cent.* 11. *n.* 28. *Comm. præl.* 53. *t.* 4.

Umbels few-flowered, leaves obovate crenate ſmooth fleſhy, petals linear.

[51. Pelargonium ſcabrum. *Rough-leaved Crane's-bill. Ait. hort. kew.* 2. 430. *L'Herit. n.* 99. *t.* 31.

Geranium ſcabrum. *Lin. ſpec.* 946. *Reich.* 3. 309. *amœn.* 4. 281. *Burm. ger.* 39. *Jacqu. ic. rar.* 3. *collect.* 2. 327.

Umbels few-flowered, leaves wedge-ſhaped ſemitrifid rugged, lobes lanceolate looſely ſerrate.

52. Pelargonium criſpum. *Curled-leaved Crane's-bill. Ait. hort. kew.* 2. 430. *L'Herit. n.* 100. *t.* 32, 33.

Geranium criſpum. *Lin. mant.* 257. *ſyſt.* 613. *Reich.* 3. 309. *Berg. cap.* 176.

G. hermanniæfolium. *Linn. ſuppl.* 305.

Peduncles ſubbifloreous, leaves doubly cordate three-lobed curled muricated.

53. Pelargonium

53. Pelargonium adulterinum. *Hoary-trifid-leaved Crane's-bill.*
Ait. hort. kew. 2. 431. *L'Herit. n.* 103. *t.* 34.
Peduncles subbiflorous, leaves cordate three-lobed waved villose soft.

54. Pelargonium exſtipulatum. *Soft-leaved Trifid Crane's-bill.*
Ait. hort. kew. 2. 431. *L'Herit. n.* 107. *t.* 35.
Geranium exſtipulatum. *Cavan. diſſ.* 4. 253. *diſſ.* 5. 271. *t.* 123. *f.* 1.
Umbels few-flowered, leaves cordate three-parted-lobed toothed hoary, ſtipules ſcarcely any.

---

55. Pelargonium ternatum. *Ternate Crane's-bill.*
Lin. ſuppl. 306. *Cavan. diſſ.* 4. 255. *t.* 107. *f.* 2. *Curt. magaz.* 413. *Jacqu. ic. rar.* 544. *collect. ſuppl.* 135.
Stem ſhrubby biſpid, leaves oppoſite ternate, leaflets wedge-ſhaped gaſh-trifid ſerrate ſcabrous.

56. Pelargonium tricolor. *Three-coloured Crane's-bill.*
Curt. magaz. 240.
P. violaceum. *Jacqu. ic. rar.* 527. *collect. ſuppl.* 129.
The two upper petals rugged at the baſe with prominent ſhining dots.

57. Pelargonium carneum. *Fleſh-coloured Crane's-bill.*
Jacqu. ic. rar. 3. 512. *collect.* 4. 189.
Stemleſs; root rapaceous ſimple; leaves bipinnate, pinnules gaſhed ſmoothiſh; five filaments fertile.

58. Pelargonium barbatum. *Bearded Crane's-bill.*
Jacqu. ic. rar. 3. 513. *collect.* 4. 196.
Stemleſs; root rapaceous ſimple; leaves pinnate; pinnas pinnatifid, lanceolate-linear, acute, bearded at the tip; five filaments fertile.

59. Pelargonium melananthon. *Dark-flowered Crane's-bill.*
Jacqu. ic. rar. 514. *collect.* 4. 188.
Stemleſs; root rapaceous ſimple; leaves pinnate ſomewhat biſpid, pinnas lobe-gaſhed blunt; five filaments fertile.

60. Pelargonium triphyllum. *Three-leaved Crane's-bill.*
Jacqu. ic. rar. 515. *collect.* 4. 199.
Stemleſs; root rapaceous ſimple; leaves ternate crenate ſmooth; five filaments fertile.

61. Pelargonium heterophyllum. *Various-leaved Crane's-bill.*
Jacqu. ic. rar. 516. *collect.* 4. 197.
Stemleſs; root rapaceous ſimple; leaves ternate and entire ſmooth ciliate, leaflets often lobed; five filaments fertile.

62. Pelargonium nervifolium. *Nerve-leaved Crane's-bill.*
Jacqu. ic. rar. 517. *collect.* 4. 198.
Stemleſs; root rapaceous ſimple; leaves ternate three-lobed and entire many-nerved ſmooth prickly-ciliate at the edge; five filaments fertile.

63. Pelargonium longifolium. *Long-leaved Crane's-bill.*
Jacqu. ic. rar. 518. *collect.* 4. 192. *Cavan. diſſ.* 235. *t.* 102. *f.* 1. *Burm. ger. n.* 67. *t.* 2.
Stemleſs; root rapaceous ſimple; leaves lanceolate acute ſmooth, the older ones often pinnate; four filaments fertile.

64. Pelargonium ciliatum. *Ciliated Crane's-bill.*
Jacqu. ic. rar. 519. *collect.* 4. 195.
Stemleſs; root rapaceous ſubſimple; leaves lanceolate acute at both ends, ciliate, ſmooth underneath, hairy above, often appendiculed; five filaments fertile.

65. Pelargonium depreſſum. *Flat-umbelled Crane's-bill.*
Jacqu. ic. rar. 520. *collect.* 4. 193.
Stemleſs; root rapaceous ſimple; leaves narrow lanceolate acute ſmooth; umbels finally depreſſed ſmooth; four filaments fertile.

66. Pelargonium longiflorum. *Long-flowered Crane's-bill.*
Jacqu. ic. rar. 521. *collect.* 4. 194.
Stemleſs; root rapaceous ſimple; leaves lanceolate acute ſmoothiſh; petals very long; four filaments fertile.

67. Pelargonium charnædryfolium. *Germander-leaved Crane's-bill.*
Jacqu. ic. rar. 523. *collect. ſuppl.* 130.
Peduncles one or two-flowered, ſtems herbaceous decumbent, leaves oblong blunt ſerrate villoſe, five filaments fertile.

68. Pelargonium trichoſtemon. *Hairy-ſtamened Crane's-bill.*
Jacqu. ic. rar. 524. *collect. ſuppl.* 131.
Peduncles few-flowered, leaves roundiſh-ovate bluntly ſerrate velvety, ſtem biennial almoſt erect, filaments birſute, five fertile.

69. Pelargonium coronopifolium. *Buck's-horn Plantain-leaved Crane's-bill.*
Jacqu. ic. rar. 526. *collect. ſuppl.* 132.
Peduncles two-flowered, leaves lanceolate-linear toothed-ſerrate, ſmooth above, ſomewhat rough-haired underneath.

70. Pelargonium bullatum. *Bladder-leaved Crane's-bill.*
Jacqu. ic. rar. 530. *collect. ſuppl.* 124.
Peduncles two-flowered, corollas four-petalled, ſtem biennial, leaves ternate, pinnotifidly lobed, ſomewhat biſpid on both ſides, five filaments fertile.

71. Pelargonium betonicum. *Betony-leaved Crane's-bill.*

Umbels many-flowered ſimple and compound, leaves cordate moſtly five lobed ſerrate tomentoſe very ſoft, ſtem fleſhy.

78. Pelargonium ribiſolium. *Currant-leaved Crane's-bill.*
Jacqu. ic. rar. 538. *collect. ſuppl.* 141.
Umbels many-flowered depreſſed ſomewhat halved, leaves cordate three-lobed ſerrate ſomewhat birſute, lobes lobed gaſhed, ſtem fleſhy.

79. Pelargonium ſulcatum.
Jacqu. ic. rar. 540. *collect.* 4. 186.
Umbels four-flowered, leaves cordate-roundiſh moſtly five-lobed acutely ſerrate ſmoothiſh, ſtipules ovate, ſtem ſhrubby erect, when young rugged.

80. Pelargonium patulum.
Jacqu. ic. rar. 541. *collect.* 4. 187.
Peduncles two-flowered, leaves ſomewhat kidney-ſhaped lobe-gaſhed acutely crenate ſmooth above, ſtem ſhrubby, ſix filaments fertile.

81. Pelargonium balſameum.
Jacqu. ic. rar. 543. *collect. ſuppl.* 136.
Umbels few-flowered, leaves five-parted ſomewhat rough-haired, lobes lanceolate acute gaſhed ſomewhat rigid, ſtem ſhrubby.

82. Pelargonium hermanniæfolium.
Jacqu. ic. rar. 545. *collect. ſuppl.* 137.
Geranium herm. *Lin. ſyſt.* 613. *mant.* 569. *Berg. cap.* 177.
Peduncles two-flowered, leaves cuneate-roundiſh gaſhed rough-haired rigid diſtich, ſtem ſhrubby.

DESCRIPTIONS, &c.

These plants are natives of Africa, moſt of them from that inexhauſtible ſtore of curious, elegant and rare vegetables, particularly ſuch as are ſhrubby, or inclined to ſhrubbineſs, the Cape of Good Hope.

The diſtinctions between this genus and thoſe of *Erodium* and *Geranium*, into which the natural genus or family of *Geranium* is now divided, may be ſeen under the eſſential characters of the reſpective genera; and the reaſons for the modern diviſion, together with the circumſtances of agreement in the ſeveral branches of this natural family, are given under *Geranium*.

Erodium having by an overſight been omitted in its proper place is introduced at the end of letter E, with *Erotium* and *Erwum*.

1. Root turbinate, perpendicular, at the upper part thickened and imbricate as it were with red ſtipules. Stem none, except peduncles or ſcapes, on which there is one leaf near the origin of the umbels. Root-leaves numerous, ſome ovate almoſt entire, others laciniate and as it were pinnate, and all petioled. Stipules oblong, faſtened to the baſe of the petiole, biſid. Flowers umbelled; ſcape radical, two inches high, and divided into three or more pedicels; involucres many-leaved, acute, hairy; rays from ten to twelve, very ſhort. Calycine ſegments acute, reflex. Corolla ſmall, papilionaceous, pale in dried ſpecimens, but according to Burman, dark purple. Capſules five, ſhort, tomentoſe: the beak ſcarcely half an inch in length [a].

Introduced in 1788, by Mr. Francis Maſſon. It flowers in march [a].

2. Root thick, yelloviſh, deſcending, having few fibres. Stem ſcarcely any, except the ſcapes, which have ſometimes leaves ſometimes none. Leaves long, often with an odd leaflet: leaflets about ſixteen, ſubſeſſile, ovate-acute, aſh-coloured. Scape longer than the leaves: involucre many-parted, with ovate-acute parts; rays half an inch long, commonly ſix. Calyx deeply five-parted, the upper ſegment wider. Corolla papilionaceous, reddiſh white with deeper-coloured veins [b].

Introduced in 1788, by Maſſon. It flowers in april [b].

3. Root fleſhy, two inches thick and more, conſiſting of ſeveral irregular tubers, and frequently half a foot in width, white within, purple on the outſide, covered with a browniſh bark, and perennial. Root-leaves ſtipuled at the baſe, very many, hairy all over and ciliate, from ſix inches to a foot and more in length, ſcarcely two inches wide, petioled, bipinnate; the lower alternate, the upper oppoſite; pinnules lanceolate-linear, trifid, biſid and ſimple, acute. Umbel compound: common ſcape round, ſhort, hirſute: partial ſcapes ſeveral, ſomewhat hirſute and upright, commonly longer than the leaves: univerſal involucre conſiſting of many lanceolate, acute, hairy, ciliate, ſhort leaflets; and a few others, like the root-leaves, but much ſhorter: leaflets of the partial involucre lanceolate, acute, hirſute alſo and ciliate. Rays of the umbels or peduncles compreſſed, villoſe, an inch long. Flowers without ſcent. Calyx ſilky and ciliate, green. Petals at firſt whitiſh, but afterwards roſe-coloured; the two upper ones having blood-red ſpots at their baſe. Filaments pale; anthers deep purple. Germ villoſe, ending in a ſilky ſtyle; ſtigma purple [c].

Introduced in 1788 by Maſſon. It flowers here in april [c].

4. This has tuberous roots, from which come out three or four broad leaves, divided into ſeveral lobes, like a vine-leaf, ſpreading flat on the ground, crenated, on ſhort foot-ſtalks. Peduncles immediately from the root, about a foot high, naked, terminated by a bunch of dark-purple flowers, having long tubes, ſeſſile, and having a very agreeable odour in the evening.

[Cultivated in 1739, in the botanic garden at Chelſea. It flowers in july and auguſt [d].]

5. Root thick, roundiſh, tuberous, with ſeveral hairy leaves ſpringing from it, which are finely divided, almoſt like thoſe of the Garden Carrot, they ſpread near the ground, and among them come out the ſtalks, about a foot high, having two or three leaves of the ſame ſort, but ſmaller and ſitting cloſe: from the ſtalks ariſe two or three naked peduncles, terminated by a bunch of yelloviſh flowers, marked with dark-purple ſpots, which ſmell very ſweet after the ſun has left them.

[It was introduced before 1632, by Mr. John Tradeſcant, ſenior [e]. Johnſon ſaw it in flower about the end of july 1632, being the firſt time that it flowered with the owner [e].

6. This is a rough-haired plant. The leaves are multifid, like thoſe of Carrot. The two upper petals are aſcending; the middle ones concave, converging, incloſing the fifth petal [f].

Root tuberous: tubers oblong, gibbous, almoſt half an inch thick; ſkin of a deep brown colour; they become ſlender at bottom, and put out there many fibres. Stems ſeveral. Leaves ſpreading much or horizontal, often a ſpan long, petioled, pale green, ſmelling ſweet when handled, covered with very ſpreading, long diſtant hairs on both ſides, interruptedly and alternately tripinnate; leaflets pinnatifid, with acute, ſegments, often toothed, reflex; the lateral pinnas turned up: the bottom leaves are fewer, ſmaller, ſmoother, with wider ſegments; but the greater number are larger, more hairy, and have narrower ſegments. Petiole round, gibbous at the baſe, embracing, hairy, leaflets on a fourth part of it. At the baſe of the petioles and peduncles is a ſingle, triangular, ſhrivelling ſtipule. Peduncle obliquely aſcending, gibbous at the baſe, covered with longer thicker hairs than the other parts, ſuſtaining nine or ten flowers. Pedicels umbelled, divaricating, jointed not far from the baſe, compreſſed a little, ſwelling towards the top, two inches long, pubeſcent, ſupported by a many-leaved involucre; the leaflets lanceolate, ſhrivelling. Calycine ſegments linear, pubeſcent, reflex. Corolla ſtraw-white; petals wedge-ſhaped, ſlightly emarginate, at firſt flat, afterwards reflex; the two upper ones wider with an oblong purple ſpot; the three lower narrower with two purple diverging ſtreaks [g].

Cultivated in the Apothecaries garden at Chelſea in 1724. It flowers from july to ſeptember [g].

7. Stems proſtrate, ſtrigoſe or hiſpid, annual at the upper part. Leaves like thoſe of Alchemilla, naked but rough-haired at the edge, with the umbilicus contracted and purple. Peduncles very long, even. Flowers purple. It reſembles G. zonale, but the greateſt part of the ſtem periſhes above the root [h].

Cavanilles deſcribes it under the name of Geranium elongatum. Stem hardiſh, hiſpid, round, branched, proſtrate. Leaves oppoſite, and next the flowers ſimple, an inch and half in diameter, roundiſh-five-lobed, tooth-crenate, rugged, ſometimes glaucous, with a blackiſh or ruſeſcent zone: petioles half a foot long and more, ſometimes tinged with red. Stipules lanceolate, reflex. Common pedunle oppoſite to a leaf, upright, the length of the leaves; involucre commonly four-leaved; the leaflets acute: rays one, two or three, half an inch long, drooping when in fruit. Calyx oblong, divided deeply into five ciliate ſegments, ending in a very acute point: the upper ſegment wider, erect; the reſt from ſpreading reflex, and afterwards preſſed cloſe to the fruit: ſtreaks ten, not very conſpicuous. Corolla papilionaceous, yellow, twice as long as the calyx, with the upper petals wider, reflex, emarginate; the reſt linear. Anthers crimſon. Germ ſmall, five-cornered: ſtyle tomentoſe, green: ſtigmas reflex. Capſules very acute at the baſe: awn an inch and half long, bearded white. Seeds ruſeſcent.—It varies with a biennial ſtem, unſpotted leaves, more deeply lobed, and the common peduncles more than a foot long [i].

Introduced in 1775, by Maſſon. It flowers during the greater part of the ſummer [i].]

8. This ſends out ſeveral herbaceous ſtalks about a foot and half in length. Flowers pale bluiſh-colour, ſeveral together upon very long peduncles. There is a ſucceſſion of them during all the ſummer months, and the

ſeeds

ſeeds ripen about a month after the flowers are fallen. There is a variety of it, with a dark circle in the middle of the leaves.

[Cultivated in 1693, by Mr. Jacob Bobart[t].]

9. This has a very ſhort fleſhy ſtalk, dividing near the ground into ſeveral heads, each having many leaves, on ſeparate foot-ſtalks from the heads; they are ſoft and downy, and have a ſtrong ſcent like Aniſeed. From theſe heads come out ſeveral ſlender ſtalks, near a foot in length, proſtrate, with rounder leaves than thoſe near the root, but of the ſame texture and odour. The flowers are produced from the ſide of theſe ſtalks, three, four or five ſtanding together upon ſlender peduncles, they are white, and being ſmall make little appearance.

[It was cultivated in 1724, in the botanic garden belonging to the Apothecaries Company at Chelſea, and flowers during moſt part of the ſummer[f].

10. Stem proſtrate, four-cornered, ſmooth; as is alſo the whole plant. Leaves marked with lines. Peduncles capillary, with two or three ſmall flowers, of a pale fleſh-colour. Anthers four[g].]

This is a biennial plant, ſending out a great number of very ſlender trailing ſtalks, extending a foot and half in length. Leaves ſmall. Flowers on ſhort ſlender peduncles, coming out at every joint from the ſide of the ſtalks; they are very ſmall, and of a red-diſh colour, ſingle or ſometimes two or three together. They continue in ſucceſſion all the ſummer, and the ſeeds ripen in about five weeks after the flowers decay.

[Cultivated in 1731, by Mr. Miller[h].

11. Introduced by Mr. Francis Maſſon in 1788. It flowers here in may[i].

12. Plant depreſſed, wholly ſubtomentoſe. Petals the length of the calyx, dark purple on the outſide with a white edge, red within: the two upper ones with blood-red dotted ſtreaks at the baſe[k].

Branches long, ſimple, filiform, wrinkled, purple. Leaves petioled, ſhort, oppoſite, hirſute, odorous. Peduncles axillary, longer than the petioles, erect, ſupporting five or ſix, ſmall, irregular flowers. Calyxes hirſute. Beaks very ſhort[l].

Cultivated in the botanic garden at Chelſea in 1724[m].

13. This is an annual plant; introduced in 1775 by Mr. Fr. Maſſon. It flowers in june and july[n].]

14. This is an annual [or rather biennial] plant, with branching ſtalks near a foot high. The lower leaves ſtand upon long foot-ſtalks, but thoſe on the upper part ſit cloſe to the ſtalks. The flowers ſtand upon naked peduncles, which proceed from the ſide of the ſtalks, on the ſide oppoſite to the leaves: they grow three or four together upon ſhort ſeparate pedicels: the corolla is papilionaceous; the two upper petals, which are large, forming a kind of ſtandard, the three lower ones narrow and bent downwards; they are of a pale fleſh-colour, appear in july, and the ſeeds ripen in ſeptember; ſoon after which the plants decay.

[Linneus remarks, that the diſk of the leaf becomes browniſh, as in the next ſpecies; and that the anthers are five or ſeven.

It was cultivated in the Chelſea garden in 1724, and flowers from march to ſeptember[o].

15. Stem herbaceous, ſpreading a little, ſubpubeſcent. Leaves ternate, gaſhed, ſubſerrate, marked with lines, having almoſt upright hairs ſcattered over them, and a broad brown ſpot in the diſk; the middle leaflet wider and ſemipinnatifid. Two ſegments of the calyx have three nerves, two have one nerve, and one has two nerves. Petals four (the loweſt being wanting) pale fleſh-colour; the upper ones with purple veins. Anthers five, the alternate ones being barren[p].]

Root knobbed, tuberous, like *P. triſte*, from which come out ſeveral pretty large leaves, compoſed of many lobes, ſet along the midrib; they are narrow at the baſe, but are very much enlarged at their ends, which are rounded, and cut all along their ſide and top into many acute points. The peduncles ariſe immediately from the root, and ſometimes have one or two ſmall leaves towards the bottom, where they often divide into two naked peduncles, each terminated by a bunch of pale reddiſh flowers, which ſmell ſweet at night.

[Cultivated by Mr. Miller in 1731. It flowers from may to auguſt, and is ſomewhat ſhrubby[q].

16. Introduced in 1768, by Mr. William Malcolm. It flowers moſt part of the ſummer[r].

17. This has a thick fleſhy knotted ſtalk, riſing about two feet high, ſending out a few ſlender fleſhy branches, thinly ſet with leaves, which on the lower part of the ſtalk are petioled, but above are ſeſſile. The flowers are produced in ſmall cluſters at the ends of the branches: the petals are narrow and white, making no great appearance; they continue in ſucceſſion moſt part of the ſummer.

[Cultivated in Chelſea garden in 1724[s].

18. Native of the South-weſt coaſt of Africa. Introduced in 1786, by Mr. Anthony Hove. It flowers in may[t]; and continues to do ſo during moſt of the ſummer months: the ſeeds ripen here[u].

19. Root perennial. Stem a foot or two in height, nearly erect, ſimple, ſwelled, round, glaucous, ſmooth, leafy, flowering at the top. Leaves ſcattered, much ſpreading, glaucous, ſmooth: leaflets alternate, wedge-ſhaped, irregularly cut, and ending in ſharp teeth: foot-ſtalks round. Stipules in pairs, ſmall, acute, membranous, brown. Panicles one or more at the top of the ſtem, alternately ſuperdecompound, ending in numerous umbels of from three to five flowers. Peduncles and pedicels round, a little fleſhy, ſlightly downy. Bractes ſolitary or in pairs at each diviſion of the panicle, ſmall, ovate, acute, concave, membranous, brown. Involucres about five at the baſe of each umbel, ſhaped like the bractes, but leſs acute, ciliated on the margin, reflexed. Flowers very numerous, inodorous, rather elegant than ſplendid. Calyx-leaves blunt iſh, membranous at the edge, ſlightly downy at the tip, bent back in the middle; the uppermoſt a little broader, ending in a honey-bearing tube of its own length, and about one fifth of the length of the pedicel with which it is connected. Petals all of an equal length, white; the two upper ones criſped on each ſide at their baſe, and ſpotted with purple. Five filaments half as long as the other five, and deſtitute of anthers; the five fertile ones being ſcarcely ſo long as the petals, declining, the uppermoſt rather ſhorter than the reſt. Anthers large, incumbent, ſcarlet. Germ roundiſh, ſmall, with five furrows, clothed with thick down. Style ſtraight, ſcarcely ſo long as the fertile ſtamens, very woolly towards the baſe, perfectly ſmooth above. Stigmas blunt iſh, red.

This ſpecies is allied to the preceding, but appears to be diſtinct, on account of the dilated, pointed, and not obtuſe, diviſions of the leaves; more eſpecially from the criſping and waving of the upper petals, and all of them being obtuſe; not to mention its panicled (not ſolitary) umbels.

It flowered in april 1792, at the Marchioneſs of Rockingham's; to whom the ſeeds, brought by Captain Riou of the Guardian, were given by the Rev. Mr. Spragg[v].]

20. This has a round fleſhy ſtalk with ſwelling knots at the joints, riſing about three feet high, and ſending out ſeveral irregular ſmooth branches. Leaves thinly diſpoſed, ſmooth, fleſhy, gray, ending obtuſely, and ſtanding on ſhort foot-ſtalks. Flowers four or five on a peduncle. Petals dark-purple, broader than in *carnoſum*, and having a very agreeable ſcent in the evening.

[Cultivated in the Chelſea garden in 1712. It flowers moſt part of the ſummer[w].]

21. This has a fleſhy ſtalk, which ſeldom riſes a foot high, and puts out very few branches. Leaves ſmooth, light green. Peduncles ſhort, having at the top two or three flowers, with unequal petals of a deep ſcarlet colour. The leaves fall off, and the ſtalks being deſtitute of them for three or four months in ſum-

[a] Hort. kew. [b] Hort. kew. [c] Burm. [d] Idem. [e] Linn. mant. [f] Idem. [g] Idem. [h] Idem. [i] Linn. mant. [k] Idem. [l] Hort. kew. [m] Idem. [n] Linn. mant. [o] Idem. [p] Linn. mant. [q] Hort. kew. [r] Idem. [s] Curtis. [t] Idem. [u] Smith. [v] Idem. [w] Hort. kew.

mer,

mer, appear as if they were dead, but in autumn they put out freſh leaves again.

[Cultivated in 1731, in the garden of James Sherard, M. D. at Eltham. It flowers during moſt part of the ſummer[a].

22. Stem ſhrubby, twiſted, branched, more than four feet high. Leaves oppoſite, often ſhorter than the petioles, oblong, with deep rounded ſinuſes; lobes oblique, wider above, roundiſh, crenate. Stipules ſhort, wide, half embracing, ſhrivelling. Peduncles axillary, ſolitary, longer than the petioles: involucre one-leafed, divided into ſix or ſeven ovate concave ſegments, rays commonly ſix, half an inch long. Calyx oblong-ovate, with the ſegments reflex. Anthers ſaffron-coloured, ſomewhat oblong[b]. There are two varieties, larger and ſmaller. Introduced in 1774 by Maſſon. It flowers from march to auguſt[b].

23. Stem ſhrubby, covered with an aſh-coloured bark, branched, two feet high. Leaves numerous, alternate, nearly equal to the petioles, very deeply five-cleft; the ſegments pinnate and bipinnate, linear. Stipules wide, acuminate and ſhrivelling. Peduncles axillary, ſolitary, with one, two or three flowers: involucre generally five-cleft, ſhrivelling. Calyx ovate-oblong, pubeſcent, cut deeply into five ovate ſegments. Corolla papilionaceous, roſe-coloured with red lines; the claws white; the two upper petals reflex and wider. Anthers deep-fleſh-coloured. Germ very ſmall, ovate-pentagon; ſtigmas villoſe, purple, revolute. Capſules villoſe, acute at the baſe: awn or tail bearded, twiſted, near four lines in length. The whole plant has a ſtrong ſmell of turpentine. The leaves in young plants are often three inches long; but in old ones only one third of the ſize and more numerous[c].

It takes the name *Radula*, from the rough raſp-like ſurface of its leaves. There are two varieties of this, as of the preceding, a larger and a ſmaller: and as it is readily raiſed from ſeeds, it affords many ſeminal varieties. The caſe is the ſame in other ſorts; inſomuch that we may hereafter find it difficult to reduce theſe plants to their proper ſpecies[d].

It was introduced by Maſſon in 1774; and flowers from march to july[e].

24. Stem arboreſcent, a fathom in height, branched; the tender branches pubeſcent. Leaves alternate, but ſometimes oppoſite, ſmooth underneath and whitiſh, above deep-green. Stipules wide, emarginate or acuminate, ſhrivelling. Peduncles ſolitary, oppoſite to the leaves, longer than the petiole: involucre five-leaved; rays about five. Calyx deeply cut into five ſegments, ſomewhat bent back. Corolla papilionaceous, pale purple, with deeper lines on the upper petals, which are wider and reflex. Seven of the filaments have anthers. The plant has a ſtrong ſmell, which varies, and reſembles turpentine, or lemon or roſes[f].

It was introduced by Maſſon in 1774, and flowers from march to july[g].]

25. This riſes with an upright ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral ſide branches, with large, angular, rough leaves, on ſhort foot-ſtalks. The flowers are produced in large panicles (umbels) at the end of the branches: the two upper petals, which are pretty large, turn upwards, and are finely variegated; but the three under ones are very ſmall, and being bent back, are ſcreened from ſight, unleſs the flower be viewed near.

[It was cultivated in the botanic garden at Chelſea in 1724: and flowers from april to july[h].]

26. This riſes with a ſoft ſhrubby ſtem to the height of eight or ten feet, ſending out ſeveral branches, which are generally erect. Leaves of a thick ſubſtance, and a lucid green, on pretty long foot-ſtalks, covered with ſoft hairs on their under ſide. Flowers in looſe bunches (umbels), on long, ſtiff, axillary peduncles. Corolla bright ſcarlet. The flowers make a fine appearance, and there is a ſucceſſion of them during all the ſummer months.

[a] Hort. kew. [b] Cavanilles. [c] Hort. kew.
[d] Cavanilles. [e] Curtis. [f] Hort. kew.
[g] Cavanilles. [h] Hort. kew. [i] Idem.

[The leaves, when bruiſed, ſtain the fingers of a ferruginous colour; hence Linneus's trivial name.

It was cultivated in 1714, by Biſhop Compton; and flowers from may to ſeptember[i].

27. In the flowers this perfectly reſembles the preceding; but the herb is ſmaller; the leaves are not tomentoſe, but are very like thoſe of *P. acetoſum*, but they are neither wedge-ſhaped at the baſe nor kidney-form, they are alſo leſs four[k].

Cultivated in 1732, by James Sherard, M. D. It flowers with the other[l].]

28. This riſes with a ſhrubby ſtalk four or five feet high, and divides into a great number of irregular branches, ſo as to form a large buſh, frequently eight or ten feet in height. Leaves indented on the edge in ſeveral obtuſe ſegments, cut into ſhort teeth: there is a purpliſh curved zone in form of a horſe-ſhoe, from one ſide of the baſe to the other, correſponding with the border: when gently rubbed, the leaves have a ſcent like ſcalded apples. The flowers are produced in pretty cloſe bunches, on axillary peduncles, five or ſix inches in length, coming out towards the ends of the branches; they are of a reddiſh purple colour, and continue in ſucceſſion great part of the ſummer. There is a variety with fine variegated leaves [and the flowers vary much in colour from purple, through the different ſhades of red to high ſcarlet.—Cultivated in 1710, by the Dutcheſs of Beaufort.

29. Cultivated in 1786, by Meſſrs. Lee and Kennedy.

30. Cultivated in 1784, by Mrs. Norman[m].

31. Stem ſhrubby, twiſted, covered with an aſh-coloured bark; branches round, villoſe, ſubherbaceous, a foot long. Leaves oppoſite, on long petioles, glaucous, rugged; lobes curled, toothed. Stipules almoſt embracing, acuminate. Common peduncle often oppoſite to a leaf or lateral, ſometimes axillary, longer than the leaf: involucre one-leafed, many-parted, ſhrivelling; rays about thirteen, ſcarcely an inch long. Calyx deeply five-parted: ſegments ovate, villoſe, reflex; ſtreaks obliterated. Corolla almoſt regular, papilionaceous-wheel-ſhaped; the upper petals a little wider, all quite entire, with a white border, and beautifully variegated with dark-purple ſpots. Three filaments barren; the other ſeven longer, fertile, with reddiſh-yellow anthers. Germ five-cornered, villoſe: ſtyle woolly at the baſe, and the reſt of it fleſh-coloured[n]. Jacquin obſerves, that the whole has a very ſtrong ſmell: and Curtis, that it obviouſly differs from all the other ſpecies, in the particular ſhape of its leaves, and the colour of the flowers, which are uſually of a rich and very dark purple edged with white.—Introduced in 1778, by John Earl of Bute. It flowers from june to auguſt[o].]

32. This riſes with an upright ſhrubby ſtalk to the height of ſeven or eight feet, ſending out many pretty ſtrong branches. Leaves ſomewhat like thoſe of the Vine; the lower on long petioles, the upper on ſhort ones; when rubbed, they have a ſcent of balm. The flowers grow in compact cluſters, on the top of long, naked, axillary peduncles, riſing much higher than the branches; being ſmall and of a pale blue colour, they make no great figure; but there is a ſucceſſion of them moſt part of the ſummer.

[It was cultivated in 1724, in Chelſea garden[p]. L'Heritier has figured a variety of it.]

33. This riſes with a ſhrubby ſtalk four or five feet high, dividing into ſeveral weak irregular branches. Leaves divided into three unequal lobes, which are hairy, and waved on their edges; they are placed alternately, and their foot-ſtalks are hairy. The flowers grow in cloſe roundiſh heads, forming a ſort of corymb; they are of a purpliſh blue colour, and continue in ſucceſſion great part of the ſummer. The leaves, when rubbed, have an odour like dried roſes.

[Introduced in 1690, by Mr. Bentick[q].

34. Stem ſhrubby, covered with a gray bark, three feet high and more; branches declining and decum-

[k] Hort. kew. [l] Linn. mant. [m] Hort. kew.
[n] Idem. [o] Cavanilles. [p] Hort. kew.
[q] Idem. [r] Idem.

bent,

bent, green, clammy, as is the whole plant. Leaves alternate, the uppermoſt ſometimes oppoſite, often ſhorter than the petioles, large, acute, ſinuate. Stipules wide-acuminate, ſhrivelling. Common pedunclés axillary, lateral, or oppoſite to a leaf, erect, ſolitary, longer than the leaves: involucre five-leaved, the leaflets ovate-acute, ſhrivelling: rays from three to eight, half an inch long. Calyx ovate, villoſe, deeply five-parted; the ſegments reflex. Corolla much larger than the calyx, papilionaceous, pale purple, variegated with red ſtreaks; the two upper petals wider, reflex. Seven of the filaments long, purple, villoſe, with oblong anthers; the other three very ſmall and barren. Germ ſmall, five-cornered, villoſe: ſtyle pyramidal, villoſe, white: ſtigmas purple. Capſule tomentoſe, ſharp at the baſe: awn an inch long, bearded white, ſpiral [f].

The middle of the leaf is generally ſtained with purple [g]. It was introduced about the year 1777, by Meſſrs. Kennedy and Lee, and flowers in may and june [h], even to ſeptember. Several varieties have been produced from ſeed [i].]

35. This riſes with a ſhrubby ſtalk eight or ten feet high, ſending out ſeveral irregular branches. Leaves roundiſh, with the ſides erect, ſo as to form a hollow or hood, whence Linnæus calls them cowled; they are heart-ſhaped at the baſe, or kidney-ſhaped, according to Linnæus, and from the footſtalk run many nerves ariſing from a point, but diverging towards the ſides; the borders are ſharply indented; thoſe on the lower part of the branches have long foot-ſtalks, and are placed without order on every ſide, but thoſe on the upper part have ſhorter foot-ſtalks, and ſtand oppoſite. The flowers are produced in large panicles or (umbels) on the tops of the branches. The calyx is deeply cut, and cloſely covered with ſoft hairs. The petals are large, entire, and of a purple blue colour. It flowers from june to ſeptember; and the ſeeds have ſhort hairy beaks.

[The whole plant is pubeſcent, higher than moſt of the other, ſtiffer and more upright. Leaves alternate, contracted at the baſe, without any apparent lobes, waved, crenate. Tube of the calyx ſhorter than the border. Petals fleſh-coloured with red veins; in the two upper ones the veins are very dark purple [k].

Introduced in 1690, by Mr. Bentick [l].]

36. This bears much reſemblance to the preceding, and has been confounded with it, but the leaves are of a thicker ſubſtance, divided into many acute angles, having purple edges, which are acutely indented. The ſtalks and leaves are very hairy. The branches are not ſo irregular as thoſe of the former, nor are the bunches of flowers near ſo large.

[It was cultivated in the Chelſea garden in 1724; and flowers in july and auguſt.

37. Cultivated in 1784, by Mr. Archibald Thompſon. It flowers in april and may [m].

38. Stem ſhrubby, branched; when young red, when very young green and villoſe, when old covered with an aſh-coloured bark. Leaves alternate, almoſt equal to the petioles, tomentoſe, whitiſh underneath. Stipules ſubovate. Flowers at the ends of the ſtem and branches in numerous umbels. Calyx ovate-oblong, very tomentoſe; the ſegments acute, ſtriated, the upper one wider. Corolla papilionaceous, large, pale purple, the two upper petals wider, longer, marked with deeper-coloured lines, red from the claws to the middle; the three lower whitiſh, linear. The ſeven fertile filaments much longer than the other three. Anthers ovate-oblong, yellow [n].

Introduced in 1774, by Mr. Maſſon. It flowers from march to july [o]. There are ſeveral varieties of it.

39. Stalk green, ſurface ſmooth and ſomewhat gloſſy, beſet with ſpines which bend back and terminate in browniſh weakiſh points; theſe appear to have been primarily the ſtipules, which become thus fleſhy and rigid. Leaves on long footſtalks, veiny, ſoft and downy, eſpecially on the under ſide, which is of a much lighter colour than the upper. The flowering ſtem proceeds from the ſummit of the ſtalk, and is a foot or more in height: as it advances it throws out its branches or peduncles, ultimately about five in number, each of which has a leaf at its baſe, ſimilar to the other leaves of the plant, but ſmaller, and terminates in an umbel of ſeven or eight flowers. When the corolla is expanded, the hindmoſt leaf of the calyx continues upright, the others are reflex, as is uſual in this genus; they are all beſet with fine long hairs. The three lowermoſt petals are pure white, with a little gibboſity at the baſe of each: the two uppermoſt are marked with three irregular ſpots, of a rich purple colour, inclining to carmine, the two lower ſpots narroweſt and of the deepeſt colour. Six filaments have anthers, and four have none. Stigma [illegible], divided into five parts, and a little longer than the fertile filaments. In its habit this plant ſomewhat reſembles the preceding. It flowers from may to ſeptember, and in favourable ſeaſons produces ſeeds here. It varies with petals of a rich purple colour, in which the ſpots are ſimilar, but not ſo conſpicuous.—It flowered in 1797, with Mr. Colvill, nurſeryman, in the King's-road, Cheliſea [p].

40. Stems angular, angles four, ſometimes three, ſucculent as is the whole plant, procumbent when they ſhoot out into length, at firſt hairy, afterwards very ſmooth, much branched, and three feet high. Leaves alternate, almoſt equal to the petioles, orbiculate, five-lobed; the younger villoſe, tooth crenate, violet-coloured underneath, and above having a dark red zone; the older crenate, fleſhy, dark green, with a few villoſe hairs, and frequently with a zone. Stipules ſhort, ſemicircular, ſpreading, ſhrivelling. Peduncles axillary, erect, rugged, with four ſubovate ſtipules at the forks. Calyx tubular, long; ſegments acute, ſpreading, the uppermoſt wider. Corolla very handſome, papilionaceous: the two upper petals an inch and half in diameter, ſemitubular at the baſe, upright, reflex at the tip, purple on the outſide, white within, having two oblong feathered ſpots, of a deep purple colour; the two others lateral, ſickle-ſhaped, parallel, with narrow claws; between theſe come out the ſtamens and piſtil, which are long, perpendicular to the upper petals, and thence from bowed upright. Seven of the filaments very long, deep red, with dark-purple, ovate-anthers; the other three ſhorter and barren. Germ five-cornered, pubeſcent: ſtyle pyramidal, at firſt green, then purple. Capſules oblong, villoſe, ſharp at the baſe: awn an inch long, bearded, ſpiral. Seeds ſmooth, reſembling a grain of wheat [q].

A vein of ſingularity, ſays Mr. Curtis, runs through the whole of this plant; its ſtalks are unequally and obtuſely quadrangular, ſometimes more evidently triangular; its leaves few, and remarkably ſmall; its flowers, on the contrary, are uncommonly large, and what is more extraordinary have only four petals; previous to their expanſion the body of filaments is bent ſo as to form a kind of bow. There is a variety with beautifully coloured leaves.

Introduced in 1774, by Mr. Francis Maſſon. It flowers from june to auguſt [r].]

41. This has many weak ſhrubby ſtalks which require ſupport, and extend to the length of two or three feet. Leaves on ſlender foot-ſtalks, faſtened into the diſk, they are ſmooth, of a lucid green, with a circular purple mark in the middle, have an acid flavour, and are placed alternate on the branches. The flowers are on pretty long axillary peduncles, each ſuſtaining four or five purple flowers, coming out in ſucceſſion during moſt of the ſummer months: and the ſeeds frequently ripen here. [It was cultivated in 1701, by the Dutcheſs of Beaufort [s].

42. Cultivated in 1787, by Meſſ. Grimwood and Barret, at Kenſington. It flowers moſt part of the ſummer [t].

43. Native of the ſouth-weſt coaſt of Africa. Introduced in 1786 by Mr. Anthony Hove. It flowers in july [u].

[s] Ray ſuppl. [t] Hort. kew. [u] Idem.

Stem shrubby, woody, branched, almost upright, round, the thickness of a finger; three feet high and more, brown. Leaves alternate, except on the branches near the peduncles, which are opposite; they are acute, more or less five-lobed or seven-lobed, flat, glaucous underneath, above glaucous-green frequently with a dusky zone, on a long petiole, sometimes extending to six inches. Stipules ovate, acute, quite entire, glaucous with the tip of a blood-red. Common peduncles axillary, alternate, erect, firm, round, four or five inches long, ending in an umbel that has commonly four flowers. Leaflets of the involucre four or five, lanceolate, acute, quite entire, erect. Pedicels two inches long, round, grooved at top, jointed, and somewhat roughened. Flowers handsome. Leaflets of the calyx lanceolate, mucronate, ciliate; the uppermost twice as broad as the others and erect. The two upper petals large, widely wedge-shaped, purple with several branched streaks of a darker purple arising from the base, and above these a transverse band of the same colour: the three lower linear-lanceolate, blunt, flesh-coloured, spreading very much, twice as long as the calyx. Filaments purple, with flesh-coloured anthers. Germ roundish, hirsute. Stigma purple [1].

Jacquin gives Geranium tabulare of Burman and Cavanilles, with Herm. afr. p. 11. and Raii suppl. 514. 37. as synonyms of this. See n. 7.

44. Native of the south-west coast of Africa. Introduced in 1786, by Mr. Anthony Hove. It flowers in july [2].

45. Native of the island of St. Helena. Introduced in 1765, by Mr. John Bush. It flowers from may to july [3].

46. Stem shrubby, short. Root-leaves numerous, on very long petioles, tomentose: stem-leaves alternate, on short petioles. Stipules lanceolate-acuminate. Peduncles terminating, very long, three-flowered or thereabouts. Involucre of four acute converging leaflets: rays an inch and half long. Calyx ovate, tomentose; the upper segment wider. Corolla papilionaceous, twice as large as the calyx, red; the upper petals longer, wider, reflex. The pitcher of filaments ten-toothed; the teeth alternately shorter and barren: anthers dusky, oblong. Germ five-cornered; stigmas red. Capsules acute at the base; with the awn or tail an inch in length [4].

Introduced in 1774, by Masson. It flowers from may to july [5].]

47. Stem shrubby, four or five feet high, sending out several branches. Peduncles long, coming out from the side of the branches. Corolla large, red, with the two upper petals bigger than the three others.

[The flowers vary considerably both in size and colour: its foliage is different from that of the other species, and as its name imports, like that of the Birch-tree [6]. It flowers most part of the summer, and was introduced in 1786, by Masson [7]. Hence Mr. Miller's *betulinum* is supposed not to be this species.

48. The whole plant is very smooth, glaucous and in a manner whitish. Stem shrubby, with round, rod-like, declining branches, two feet high. Leaves opposite, often shorter than the petioles, which are round and erect. Stipules lanceolate-acuminate, fleshy, deciduous. Peduncles alternately axillary, very long, one or two-flowered. Segments of the calyx acuminate, the uppermost and two lower ones wider. Corolla papilionaceous, white: the upper petals wider, reflex; claws purple. Anthers pale saffron: sometimes there are only six [8].

It flowers from june to august; and was introduced in 1775 by Messrs. Kennedy and Lee [9]: from dried specimens in the possession of Sir Joseph Banks [10].

49. Root branched. Stem shrubby, two feet high and more, very much branched, smooth, round, the thickness of a reed or the little finger, almost upright, when old dusky, when young more or less blood-red. Leaves alternate, except a few of the upper ones which are opposite, petioled, three-lobed or three-parted, very seldom ternate, stiffish, veined, smooth above, muricated underneath at the midrib and principal veins, three inches long, taking in the petioles: lobes lanceolate, acute, very minutely serrated, gashed; but sometimes quite entire. The upper leaves are usually entire, lanceolate, quite smooth underneath, neither serrate nor gashed, or else one-toothed on one or both sides; but they vary so much, that the specific difference can only be taken from the lower leaves. Petioles round, the length of the leaves, smooth, seldom rough. Stipules lanceolate, acuminate, smooth, erect, first green, then red. Peduncles opposite to a leaf, smooth, slender, spreading, almost as long as the leaves, commonly one-flowered, but sometimes two-flowered. Involucre two-leaved, leaflets ovate-awned, erect, green. Pedicels half an inch long, grooved almost to the base, smooth, reddish. Leaflets of the calyx lanceolate, acuminate, four of them green with white edges; the uppermost wider, concave, erect, red. Petals wedge-shaped, rounded, whitish flesh-colour, above the claws having an oblong red spot, which in the two upper ones is wider and branched. Anthers rose-coloured. Stigma red [11].

Introduced in 1780, by Messrs. Kennedy and Lee. It flowers from may to august [12].]

50. Stem shrubby, six or seven feet high, sending out several side branches. Leaves of a grey colour, and having an acid taste like Sorrel. Peduncles axillary, long, sustaining three or four flowers, with narrow, unequal petals, of a pale bluish-colour, with some stripes of a light red. The flowers continue in succession most part of the summer.

A variety with scarlet flowers has been raised from seed.

[It was cultivated in Chelsea garden in 1724 [13].

51. Stem shrubby, round, three or four feet high, the thickness of a finger, upright, of a reddish bay colour, branching from the axils, very rough, as is the whole plant, but becoming smooth with age. Leaves on long petioles, very widely wedge-shaped, three-nerved, acute, stiffish, alternate except the upper ones next the flowers, which are opposite, the longer ones seven or eight inches in length reckoning the petioles; the lobes gashed or thinly toothed, but sometimes quite entire. Stipules small, ovate-acuminate, on each side next the petioles. Common peduncles terminating and axillary, short, sustaining commonly from four to six flowers. Calyx green: segments lanceolate, acuminate, spreading very much, shorter than the petals, very unequal in breadth. Petals blunt, of a purple rose-colour; the two upper ones twice as wide as the others, with a dark blood-red spot at the base. Anthers oblong, blood-red; as are also the stigmas. Seeds rough, with a rough beak, an inch in length [14].

Introduced in 1775, by Messrs. Kennedy and Lee. It flowers from august to november [15].

52. This is a stiff shrub. Leaves small, five-lobed, having the smell of Balm. Flowers violet. Peduncles commonly two-flowered [16]. Stipules cordate, almost imbricate on the branchlets. Involucels lanceolate [17].

Introduced in 1774, by Mr. Francis Masson. It flowers from july to november.

53. Introduced in 1785, by Mr. Archibald Thompson. It flowers in april and may [18].

54. The whole plant is very smooth and somewhat glaucous. Stem shrubby, a foot high, with round, upright branches. Leaves alternate, shorter than the petioles, mostly divided into three lobes, each of which are three-lobed at the tip, and crenate; the young ones are somewhat cowled, but afterwards become spreading. Stipules very small, in some specimens scarcely visible. Common peduncle axillary, and as it were terminating, longer than the leaves: involucre five-cleft, with the segments short and revolute:

[1] Jacquin. [2] Hort. kew. [3] Idem. [4] Cavanilles.
[5] Hort. kew. [6] Curtis. [7] Hort. kew. [8] Cavanilles.

[11] Jacquin. [12] Hort. kew. [13] Idem. [14] Jacquin.
[15] Hort. kew. [16] Linn. mant. [17] Linn. suppl.
[18] Hort. kew.

pedicels from three to five, ſcarcely half an inch in length. Calyx deeply cut into five acuminate reflex ſegments, the upper one erect. Corolla papilionaceous, pale fleſh-colour, the three lower petals hanging down, without ſpots, and white on the outſide; the two others upright, bent back at top, having ſpots of a darker colour. The leaves have a very ſweet ſmell, not unlike Sweet Marjoram; when young, and in the open air whitiſh with a very fine nap, but in the ſtove ſmooth and green [a].

Found by Mr. William Paterſon, and introduced at Kew in 1779, by the Counteſs of Strathmore. It flowers from may to auguſt [b].

55. Stem ſuffruticoſe, dichotomous, round, purple, villoſe, erect, two feet high and more: branches ſimple, ſhort, reſembling the ſtem. Leaves rigid, ſtrigoſe-rugged, an inch long; ſerratures purpliſh: petioles villoſe, the length of the leaves. Stipules two or more, ovate-acute, concave, a line in length. Flowers lateral and terminating, umbelled: involucres lanceolate, purple, ſubciliate. Calyx ciliate-hairy. Corolla whitiſh-fleſh-colour; petals oblong, entire, equal, with a double purple ſtreak at the baſe [c].—It differs very materially from the other ſpecies in the unuſual roughneſs of the ſtalks, as well as in its whole habit [d].

56. The plants of this newly-introduced ſpecies ſcarcely exceed a foot in height here, growing up with a ſhrubby ſtem, and ſpreading widely into numerous flowering branches, ſo much diſpoſed to produce flowers in a conſtant ſucceſſion, that during moſt of the ſummer the plant is loaded with a profuſion of them. For the moſt part they go off without ſeed; and when any is produced, there is generally one perfect, and four abortive. The fertile ſtamens vary in number; four are moſt uſually apparent, three ſuperior, one and often two inferior. The whole plant is covered with ſhort white hairs, which give to the foliage a ſomewhat ſilvery hue. The two uppermoſt petals are of a beautiful red, having their baſes nearly black; the three lowermoſt are white. Inſtances occur in which one or more of the white petals have a ſtripe of red; and the dark colour at the baſe of the upper petals is, in a certain degree, ſoluble in water; for on the plants being watered, the white petals here and there become ſtained by the colouring matter, which in a diluted ſtate is purpliſh: as the flowers decay, this apparently black part, diſtinguiſhed by the roughneſs of its ſurface, ariſing from prominent lucid points, is ſometimes perforated with numerous ſmall holes.

Introduced by Maſſon at Kew in 1792. Raiſed alſo from Cape ſeeds by Mr. Williams nurſery-man at Hammerſmith [e].

The above ſpecies, with very few exceptions, are natives of the Cape of Good Hope. Theſe that follow are deſcribed by Jacquin in the laſt volume of his Collectanea, and figured in the third volume of his Icones Plantarum rariorum.

57. Root rapaceous, oblong, brown, two inches long, perennial. Root-leaves many, decumbent in a ring, with a few ſmaller that are upright, about five inches in length, oblong, of a duſky green colour, almoſt ſmooth, appearing ciliate at the edge when examined by a magnifier, having ſomething of a turpentine ſmell, bipinnate. Petiole two or three inches long, above and at the edges ſomewhat hiſpid with white hairs, ſmooth underneath, winged at the baſe with a lanceolate-linear acute and ſomewhat hirſute ſtipule on both ſides: pinnas oppoſite, often three on each ſide, with an odd one at the end: pinnules decurrent, cut into two or three oblong lobes. Scape round, upright, half a foot high, purple, thinly hairy. Umbel ſimple. Leaflets of the involucre about fifteen, linear-lanceolate, acute, ſhort, hirſute, ciliate, green. Peduncles two inches long, thickiſh, about ſeven in number, ſomewhat hairy, red. Calycine leaflets linear-lanceolate, acuminate, villoſe, ciliate, green, ſpreading, about half the length of the petals; which are ſomewhat wedge-ſhaped, blunt, ſpreading but not bent back; the two upper ones three times as wide as the others, emarginate, and having branched red veins; all pale the firſt day, but afterwards fleſh-coloured, expanded in the day time, but contracted and ſhut at night. Anthers ſcarlet. Germ ſilky. Stigma purple. It flowers in march and april.

58. Root rapaceous, roundiſh, brown, perennial. Root-leaves ſeveral, half a foot long and more, on long petioles, ſmooth, bright green, winged at the baſe on each ſide with a lanceolate-linear acute red ſmooth ſtipule. Pinnas of the leaves quite entire, decurrent, with two or three hairs at the tip, ſome ſimple, others forked with two or three lines. Scapes very ſhort, ſometimes ſcarcely an inch high, upright, ſomewhat hirſute. Umbel compound, with about three rays, villoſe, ſcarcely longer than the involucel, red. Calycine leaflets linear-lanceolate, acute, almoſt equal. Leaflets of the univerſal involucre ſeveral, hirſute, lanceolate-linear, acute, unequal; one or two of them often reſembling the root-leaves, but much ſhorter and ſomewhat hirſute. Leaflets of the involucel, ſeveral, lanceolate, acute, hirſute, almoſt equal. Peduncles villoſe, ciliate, four of them ſpreading and reflex, the fifth erect. Petals linear-wedge-ſhaped, blunt, half turned back, very pale roſe-colour; the two upper ones approximating, twice as broad as the reſt, ſometimes emarginate, and marked below with two red lines; the three lower ones have only one line. Anthers oblong, vermilion. Germ green, ſilky. Style purple, villoſe. Stigma purple. It flowers in april.

59. Root rapaceous, oblong, two inches in length, perennial. Root-leaves ſeveral, ſpreading, thickiſh, with white decumbent hairs on both ſides, ciliate, four or five inches long, duſky green. Petiole roundiſh, villoſe, about two inches in length, winged at the baſe on each ſide with a lanceolate acute villoſe ſtipule. Pinnas commonly oppoſite, the loweſt often ſlightly petioled, the reſt ſeſſile and decurrent; with oblong blunt lobes. Scape an inch high, thickiſh, upright, round, hirſute. Umbel compoſed of about three rays, four or five inches long, hirſute, purple. Leaflets of the univerſal involucre few, very unequal, hirſute, one or two lanceolate, acute, the others more or leſs reſembling the root-leaves, but ſhorter. Leaflets of the involucel about ten, lanceolate, acute, hirſute, ſpreading, almoſt equal. Peduncles very many, villoſe, half an inch long. Calycine leaflets lanceolate, acute, hirſute, ciliate, with hairs, eſpecially along the dorſal nerve glandularly headed. Petals wedge-linear, blunt, upright and white to the middle, reflex and very dark purple above. Anthers oblong, of a red bay colour. Germ and ſtyle hirſute. Stigma purple. It has but little ſmell when bruiſed, and flowers in april and may.

60. Root rapaceous, the length and thickneſs of a finger, brown, perennial. Root-leaves ſeveral, ſometimes but ſeldom one or two ſmaller and lobed: leaflets ovate, bluntiſh, on very ſhort petioles, very obſcurely ciliate at the edges when examined with a magnifier, the middle one an inch and half long, but the ſide ones ſmall. Common petiole two or three inches long, hirſute, winged at the baſe on each ſide with a linear acute hirſute ſtipule. Scape two inches high, round, hirſute, erect. Umbel compoſed of two or three rays coming out in ſucceſſion, half a foot long, hirſute. Leaflets of the involucre few, lanceolate, hirſute, unequal: of the involucels ſeveral, lanceolate, acute, hirſute, ciliate, reflex, ſmall. Peduncles about ten, an inch long, hirſute. Calycine leaflets reflex, lanceolate, acute, hirſute, ciliate, almoſt equal. Petals wedge-ſhaped, blunt, upright at bottom and thence ſpreading very wide, roſe-coloured, a little longer than the calyx; the two upper ones almoſt twice as wide as the others, a little longer, with blood-red dots below. Germ ſilky. Style and ſtigma of a very dark blood red colour. It flowers in april.

61. Root rapaceous, two inches long, black, perennial. Root-leaves ſeveral, in a ring. Petiole ſomewhat hiſpid, with a lanceolate-linear hirſute ſtipule at the baſe on each ſide, and from two to four inches long, the leaves varying much even on the ſame plant; being acute or obtuſe, ternate with the middle lobe more or leſs deeply three-lobed, very large or nearly equal to the lateral leaflets, which are ſometimes quite entire, ſometimes gaſhed; ſometimes

ſimple,

[a] Cavanilles. [b] Hort. kew. [c] Cavanilles.
[d] Curtis. [e] Idem.

ſimple, ovate, ſmall, entire or obſoletely three-lobed. Scape upright, ſomewhat hiſpid, an inch or two in length, green. Umbel compoſed of three or four rays, half a foot long, purple, hiſpid. Leaflets of the involucre ſeveral, lanceolate, acute, hirſute, reflex, unequal, with one leaflet often larger and ternate: leaflets of the involucels ſeveral, linear-lanceolate, acute, hirſute, reflex, equal. Peduncles about eight, an inch long, purple, ſomewhat hiſpid. Calycine leaflets pale green, linear-lanceolate, acute, hirſute, ſpreading very much; the uppermoſt erect and concave. Petals wedge-ſhaped, ſpringing from a long upright claw, turned back at top, blunt, twice as long as the calyx, white; the two upper ones a little wider, with a long dark blood-red ſpot above the claws. Anthers oblong, fleſh-coloured. Stigma red. Germ ſilky. It flowers in march and april, and when bruiſed has the ſmell of turpentine. Jacquin ſuſpects that it may perhaps be only a variety of *P. birſutum*, *n.* 1.

62. Root rapaceous, two inches long, brown, perennial. Leaflets bluntiſh, petioled; ſome ſimple and ſubovate; others ternate; others three-lobed, with the lateral lobes ſmaller; all of them ſometimes entire, ſometimes gaſh-bifid. Petiole ſomewhat hirſute below; with a lanceolate acuminate ſtipule at the baſe on each ſide, which is alſo ſomewhat hirſute. Scape almoſt upright, about three inches high, round, roughiſh, hairy. Umbel uſually compoſed of three rays, which are half a foot in length, hairy and round. Leaflets of the involucre about eight, lanceolate, acute, almoſt equal, hirſute: of the involucel ſimilar. Peduncles from five to ten, hirſute, two inches long. Calycine leaflets lanceolate, acuminate, hairy at the back, woolly at the edges, equal, ſpreading very much, pale green with whitiſh edges. Petals twice as long as the calyx, wedge-ſhaped, very blunt, reflex and ſpreading very much, white; the two upper ones wider, with two branching red ſtripes ariſing from the baſe. Anthers oblong. Germ ſilky. Stigmas purple. It flowers in march and april, and when bruiſed has a little ſmell of turpentine.

63. Root rapaceous, roundiſh, an inch in length, brown, perennial. Root-leaves ſeveral, quite entire, ſomewhat convex, appearing ſomewhat villoſe at the edges when examined by a magnifier, often turned back a little, two inches long. Petiole of the ſame length, ſomewhat villoſe in the lower part, winged at the baſe on each ſide with a ſcarioſe, whitiſh ſtipule, which is acute and tooth-ciliate. Sometimes a few leaves come out later which are ſmaller and pinnate, the pinnas lanceolate-linear, acuminate and decurrent. Scape round, ſlender, weak, green, almoſt upright, half a foot high. Umbel compoſed of about four rays, which are half a foot long, villoſe, and lengthen ſucceſſively. Involucre many-leaved: leaflets unequal, villoſe, acute, almoſt linear, one of them often much larger and lobed. Involucels the ſame number with the flowers, linear, acute, ſomewhat villoſe, upright. Peduncles purple, half an inch long, villoſe. Calycine leaflets linear-lanceolate, acute, villoſe, green, ſpreading. Petals wedge-ſhaped, blunt, half-reflex, uniformly red-purple, the two upper ones a little wider. Anthers oblong, red with a yellow pollen. Germ roundiſh, five-grooved, green, ſilky, with white hairs. Style and ſtigma red. It flowers in march and april.

64. Root rapaceous, fuſiform, brown, three inches long, perennial. Leaves narrowly and elongately lanceolate, quite entire, about three inches long, with a hirſute petiole of the ſame length, hairy above and at the edges; ſome have a ſmall linear-lanceolate ſharp leaflet or two at their baſe; at the origin of the petiole on each ſide they are winged with a lanceolate ſharp hirſute ſtipule. Scape half a foot high and more, round, upright, hirſute. Umbel compoſed of three or four rays, which are three inches long and hirſute. Leaflets of the involucre ſeveral, linear-lanceolate, acute, hirſute, with one of them commonly much larger than the reſt: thoſe of the involucel ſimilar, but all nearly equal. Peduncles five or more, half an inch long, hirſute. Calyx green, hirſute; leaflets lanceolate, acute, four of them ſpreading very much, the uppermoſt erect. Petals linear-cuneiform, bluntiſh, erect at bottom, but ſpreading very much at top, twice as long as the calyx, pale yellow; the three lower unſpotted, the two upper above the claw to the middle of the border dark blood red. Anthers red. Germ villoſe. It flowers in may.

65. Root rapaceous, roundiſh or oblong, brown, perennial. Root-leaves ſeveral, very much narrowed at the baſe, quite entire, appearing ſomewhat villoſe at the edge when examined by a magnifier, bright green, three or four inches long. Petiole two or three inches in length, ſomewhat villoſe, winged at the baſe on each ſide with an acute ciliate purple or white ſtipule. Scape ſlender, upright, round, almoſt ſmooth, half a foot high and more. Umbel compoſed of three or four rays, which are four inches long, round and villoſe. Leaflets of the involucre about five, lanceolate-linear, acute, ciliate, unequal: of the involucel linear, acute, villoſe, ſmall, ſpreading, about the ſame number with the flowers. Peduncles about eight, an inch long, ſomewhat villoſe, channelled, forming at firſt a convex umbel, but afterwards ſpreading out ſo much, that the umbel is flat and depreſſed. Calycine leaflets linear-lanceolate, acute, villoſe, ſpreading very much, green with white edges, one third only of the length of the petals: which are lanceolate-linear, ſharpiſh, half turned back, pale yellow; the two upper ones a little wider and dark blood red in the middle. Filaments nine only, of which five are ſhort and barren, the anthers on the other four are oblong and ſcarlet with a yellow pollen. Germ long ovate, villoſe, green. Style and ſtigma blood-red. It flowers in march and april.

66. Root rapaceous, oblong, brown, perennial. Root-leaves ſeveral, very much narrowed at the baſe, quite entire, appearing ſomewhat villoſe at the edge when magnified, from three to five inches long, with a ſmoothiſh petiole nearly of the ſame length, having a narrow-lanceolate, acute, ſmoothiſh ſtipule on each ſide. Scape round, ſmoothiſh, flexuoſe, weak, about half a foot in height. Umbel compoſed in general of two rays, which are villoſe and about half the length of the ſcape. Leaflets of the involucre few, linear-lanceolate, acute, villoſe, unequal, one or two reſembling the radical leaves, but ſcarcely two inches long: thoſe of the involucel equal. Peduncles from four to ſeven, villoſe, an inch or an inch and half in length. Calyx green: leaflets linear-lanceolate, acute, villoſe; the upper one erect, the reſt reflex. Petals linear, ſharpiſh, channelled, erect at bottom, but ſpreading very much above, an inch and half long, very pale yellow, with a longitudinal purple band above the claw, of a very deep colour in the two uppermoſt petals: the uppermoſt petal is ſometimes ſo deeply cloven that the corolla appears to be ſix-petalled. Filaments ten, extremely ſhort. Anthers four, oblong, obtuſe, red. Germ villoſe. It flowers in may.

All the above ſpecies from *n.* 57. inclufive, are natives of the Cape of Good Hope, and belong to the firſt diviſion.

67. Root branching, annual. The whole plant villoſe, and ſmelling rather diſagreeably. Stems ſeveral, branched, diffuſed, from ſix to ten inches in length, the thickneſs of a pigeon's quill at the baſe, round, jointed, knobbed, in the primary diviſions dichotomous, more or leſs of a duſky purple. Leaves petioled, oppoſite, entire, thickiſh, hoary green, the largeſt ſcarcely an inch long, but moſt of them only half that length. Stipules lanceolate, acute, ſmall, withering in a ſhort time. Peduncles axillary, alternate, longer than the leaves. Leaflets of the involucre about four, lanceolate, acute, ſmall. Pedicels ſhortly grooved above. Flowers very ſmall. Calyx green and ſomewhat rough-haired; leaflets lanceolate, drawn to a point and ending in a briſtle, erect, the uppermoſt a little wider. Petals the length of the calyx, wedge-ſhaped, blunt, upright, ſpreading a little at top, white with a dark-purple diſk; the two uppermoſt twice as broad as the other three. Anthers yellow. Germ hirſute. Stigma five-cleft, purple, ſomewhat villoſe. Seed hirſute; the tail half an inch long and bearded.

68. Root branched, biennial. Stem branching from the

the very bottom, ſo that it appears to be many-ſtemmed, the thickneſs of a reed, round, a foot high, when young very ſoft and like velvet, as are alſo the other parts of the plant. Leaves ſcattered, blunt, nerved and veined, flat except that they are often a little waved at the ſerratures, thickiſh, ſomewhat hoary on both ſides, an inch or an inch and half in length. Petiole round, from three to ſix inches long. The uppermoſt leaves are oppoſite. Stipules on each ſide of the petioles, ovate-acuminate, quite entire, upright, preſſed cloſe, often duſky purple, towards the bottom of the branches imbricate. Common peduncles erect, about three inches long, umbelled. Leaflets of the involucre few, ovate, acute, ſmall. Pedicels from one to three, erect, an inch and half long, very ſhortly grooved at top. Calycine leaflets ovate, bluntiſh, concave, three-ſtreaked, bearded at the tips, ſpreading, pale green, three of them twice as wide as the other two. Petals very blunt, uniformly red-purple, ſpreading very much above the claws, the two upper ones very wide and roundiſh, the other three oblong. Filaments united almoſt up to the middle, very cloſely villoſe on the outſide with capitate hairs; five of them alternately awl-ſhaped, white, and alſo a little capitately villoſe, have haſtate yellow anthers; of the five barren ones the three lower are very ſhort, the two upper are as long as the fertile ones, ſimply hairy, and purple at the tip. Germ hirſute. Stigma ſcarlet. It flowers in march and the following months.

69. Root branching, the thickneſs of a reed, brown, long. Stems few, procumbent, half a foot high, round, perennial, more ſlender by half than a reed, covered with the imbricate permanent brown ſtipules of fallen leaves; which are acute, ſimple, tooth-ſerrate towards the end, but quite entire in the other parts, thickiſh, often ſomewhat keeled, narrowing at the baſe into the petiole, the larger ones half a foot in length, ſpreading, cloſely imbricate on the ſtems, but on the flowering branches diſtant, alternate except the uppermoſt, which are oppoſite. Stipules lanceolate, acuminate, erect, quite entire, appearing ciliate and ſilky by a magnifier, growing to the petioles. Peduncles oppoſite to the leaves and axillary, alternate, erect, villoſe, ſoft, three inches long, the loweſt umbelled two-flowered, the reſt three-flowered. Leaflets of the involucre commonly five, lanceolate, acute, ciliate, a little rough-haired, as are alſo the pedicels and calyx. Pedicels two inches long, ſhortly grooved at top. Calycine leaflets lanceolate, acute, ſpreading very much and reflex; the uppermoſt a little wider. Petals blunt, ſpreading very much, white at the claws, the reſt purple; the two upper ones very wide, obovate, with the claw on each ſide produced and wedge-ſhaped; the three lower from a narrow claw oblong. Filaments declined, awl-ſhaped; five longer with anthers, which are oblong and tawny red: of the five barren ones, four are white and the upper one purple. Germ and ſtyle hirſute. Stigma ſmooth, purple. The little ſmell it has is unpleaſant. It flowers in june and july.

There is a variety which has ſmaller flowers, with the claw of the two upper petals white and crowned with a deep-red band: all the leaves are linear-lanceolate, and gaſh-ſerrate almoſt their whole length.

70. Root branched. Stem round, the thickneſs of a reed, duſky, dividing preſently into ſeveral branches or ſtems, procumbent, round, ſubdivided, herbaceous, a foot and half long, appearing very cloſely and ſhortly villoſe in the magnifier, but neither hairy nor hirſute. Lower leaves alternate, the reſt oppoſite, petioled, ſomewhat hiſpid on both ſides when viewed in a glaſs, ſhortly ciliate, above deep green with the diſk ſometimes browniſh, pale green underneath, oblong, blunt, gaſh-ſerrate, ſome of the lower ones entire, the next ternate, with the lateral leaflets more or leſs roundiſh and lobed, the middle leaflet ſubpinnatifid; upper leaves pinnatifid; almoſt all ſo rolled back as to be convex and reſemble a bladder. Stipules ovate, acute, thinly ciliate with long hairs. Common peduncles axillary, a few oppoſite to a leaf, round, ſomewhat villoſe, longer than the leaves. Leaflets of the involucre commonly four, lanceolate, acute, green, ſomewhat villoſe in the magnifier, ſpreading or reflex. Pedicels ſcarcely half an inch long, grooved almoſt to the baſe, ſomewhat rough-haired, duſky purple. Calycine leaflets lanceolate, acuminate, ſtriated, villoſe, ſpreading; the uppermoſt wider than the reſt. Petals always four, very pale purple or fleſh-colour, twice as long as the calyx; the two upper ones from a long claw widen into a rounded very broad lamina, ſtand erect, and from the bottom have two branching red lines; the two lower ones are long lanceolate, reflex above the claws, ſhorter than the upper ones and much narrower. Anthers ſcarlet. Stigma blood-red. Fruit hirſute, two inches long. Seeds acuminate at the baſe, hirſute with a feathered awn. It flowers in the ſummer, and when rubbed has an unpleaſant ſmell.

71. Root brown, round, the thickneſs of a reed, biennial. Stems ſeveral, procumbent or aſcending, branched, herbaceous, round, attaining the height of eighteen inches. Leaves oblong, blunt, crenate, ſtiffiſh, on long petioles, dark green with the diſk frequently browniſh, alternate except the uppermoſt. Stipules ovate, acute. Common peduncles axillary and oppoſite to a leaf, commonly two-flowered, ſeldom one-flowered or three-flowered, two or three inches in length. Leaflets of the involucre few, lanceolate, acute. Pedicels half an inch long, grooved almoſt to the baſe. Calycine leaflets lanceolate, acute, ſtriated; the uppermoſt twice as broad as the others. Petals wedge-ſhaped, blunt, ſpreading, fleſh-coloured or white, twice as long as the calyx; the two upper ones much larger and having two branching red lines. Anthers oblong, red. Stigma blood-red. Awn of the ſeed feathered and two inches long. It flowers in ſummer, has but little ſmell, and is rough-haired all over.

72. Root branched. Stem herbaceous, round, procumbent or almoſt erect, the thickneſs of a reed, a foot and half high, branched, blood-red next the ſun. Leaves on long petioles, alternate or oppoſite, oblong, blunt, hiſpid at the edges and underneath on the nerves and veins, having a few hairs ſcattered over the upper ſurface, ſpreading, the largeſt five inches long, with a petiole three inches in length and hirſute; the loweſt ſimple and pinnatifid; the reſt ternate, with the lateral leaflets roundiſh lobed and gaſhed, the middle one oblong and pinnatifid with the ſegments approximating and gaſhed, the loweſt of them even lobed. Stipules ſubcordate, acuminate, hirſute, ciliate, green, ſpreading very much. Common peduncles oppoſite to a leaf, a few of them axillary, round, ſomewhat hirſute, from three to ſix inches long, umbelliferous. Leaflets of the involucre about five, lanceolate-ovate, acute, ſomewhat hirſute, ciliate, reflex. Pedicels commonly five, round, ſomewhat compreſſed, rough-haired, grooved almoſt to the baſe, half an inch long. Calycine leaflets long-lanceolate, acute, ſomewhat rough-haired, ſtriated, ſpreading, the uppermoſt wider. Petals blunt, ſpreading, pale fleſh-colour; the two uppermoſt obovate, very wide, with two branching blood-red ſtreaks above the claw; the three lower ones much ſhorter and narrower, almoſt ſpatulate. Anthers oblong, red. Germ hirſute. Stigma blood-red. Fruit rough-haired. It flowers from may to july, and has an unpleaſant ſmell.

73. Root branched. Stems ſeveral, herbaceous, at moſt the thickneſs of a reed at bottom, round, often jointed and knobbed, duſky purple, wholly procumbent, and cloſely hirſute with white hairs, three feet high, branched. Leaves on long petioles, the lower alternate, the upper oppoſite, ciliate, ſomewhat hirſute underneath along the nerves and veins, the reſt ſmoothiſh, appearing dotted when examined by a magnifier; the nerve and veins on the back often purple; the lateral leaflets lobed and gaſh-ſerrate, the middle one lengthened out, three inches long, pinnatifidly cut into oblong diſtant lobes gaſh-toothed at top; petiole hirſute. Stipules ovate, acute or truncated, ciliate, hirſute. Common peduncles oppoſite to a leaf, axillary and terminating, umbelliferous, erect, from two to four inches long, hirſute. Leaflets of the involucre about four, lanceolate, acuminate, ſtriated, ciliate,

ſomewhat hirſute. Pedicels from one to five, grooved almoſt to the baſe, ſomewhat rough-haired, half an inch long. Calycine leaflets oblong-lanceolate, acuminate, ſtriated, ſpreading, ſomewhat rough-haired. It reſembles the preceding very much; but it has very ſeldom five petals, and has always ſeven fertile filaments. It flowers from may to july, and has a diſagreeable ſmell.

74. Root the thickneſs of a reed and more, about three inches long, round, branched, pale. Stems numerous, procumbent except at the end, where they aſcend in a bow ſtiffly, branched, round, ſmooth, ſomewhat villoſe towards the top, knobbed, blood-red at the joints, duſky purple at bottom, in other parts green with a tinge of purple here and there, herbaceous, two feet long, the thickneſs of a pigeon's quill. Leaves alternate, except the upper ones, which are oppoſite, two or three inches in length reckoning the petioles, three-lobed, gaſhed, blunt, ſmooth, green; the ſide-lobes on very ſhort petioles, ſubovate, in the larger ones three-lobed; the middle lobe lengthened out and pinnatifid. Stipules ovate, acuminate, ſmooth, blood-red. Peduncles round, appearing ſomewhat villoſe when magnified, terminating and axillary, erect, rigid, almoſt as thick as the ſtem, green, about two inches in length. Leaflets of the involucre commonly five, ovate, acute, concave, pale green with blood-red ſtreaks, ſpreading very much. Pedicels grooved two-thirds of their length, villoſe, ſcarcely longer than the involucre, almoſt upright, dark blood-red. Calycine leaflets oblong, mucronate, ſtreaked, ſpreading, blood-red, the uppermoſt twice as wide as the others. Petals ſpreading, deep purple, with deeper purple bands above the claw; the two upper ſpatulate, ſubemarginate, almoſt twice as long as the calyx; the two lower blunt, leſs than half the breadth and much ſhorter than the others. Filaments awl-ſhaped, ſhorter than the calyx, purple. Anthers oblong, erect, fleſh-coloured with a yellow pollen. Germ villoſe. Stigma purple. Fruit hirſute. Seeds villoſe, with a feathered awn an inch in length. It flowers in april and the following months, and is void of ſmell.

75. Root round, the thickneſs of a reed, browniſh. Stem round, the thickneſs alſo of a reed, a foot high, branched, ſomewhat rugged, rough-haired, hiſpid, erect, with the lower branches ſomewhat ſpreading. Leaves oblong, alternate except the upper ones, which are oppoſite, blunt, appearing dotted on both ſides when examined by a magnifier; underneath and at the edges roughiſh with white hairs, pinnatifidly lobed, gaſhed, crenate, the largeſt three inches in length, with a petiole two inches long and hirſute; the uppermoſt ſeſſile and ſtiffiſh; the loweſt lobes of the larger leaves commonly diſtinct; inſomuch that the leaves are then ternate: the uppermoſt leaves in ſome individuals are bipinnatifid. Stipules roundiſh, acute, ciliate. Peduncles oppoſite to a leaf or axillary, round, thickened at the baſe, ſomewhat rugged, two inches long. Leaflets of the involucre about ſeven, lanceolate, acute, ſtriated, ciliate, reflex. Pedicel rugged, roughiſh, erect, grooved almoſt to the baſe, half an inch long. Calycine leaflets lanceolate, acuminate, roughiſh, ciliate, ſpreading, green with purple ſtreaks, the upper one a little wider. Petals wedge-ſhaped, roſe-coloured, twice as long as the calyx, blunt, ſpreading; the two upper ones much wider and marked with branched blood-red lines. Anthers blood-red. Stigma of the ſame colour, villoſe above. Fruit hirſute: awn an inch and half in length. It flowers in the ſummer, and when bruiſed has an unpleaſant balſamic ſmell.

76. Root round, the thickneſs of the little finger, half a foot long. Stem procumbent, twiſted, ſhrubby, branched, the ſame ſize with the root, brown, rough with the indurated ſcars of fallen leaves; when young fleſhy and hirſute. Leaves on long petioles: pinnas oppoſite; pinnules linear, acute, quite entire, ſeſſile. Stipules lanceolate, acute, faſtened to the petiole on each ſide. Peduncles hirſute, roughiſh, ſpreading, three or four inches long, ſuſtaining from three to five flowers in an umbel. Leaflets of the involucre commonly five, lanceolate, acuminate, ciliate, ſpreading, green. Pedicels ſhort, hirſute, grooved to the middle. Calycine leaflets lanceolate, acute, hirſute, ſpreading, the upper one twice as wide as the reſt. Petals ſpatulate, blunt, ſpreading, red purple; the two upper ones nearly twice as wide as the others and of a deeper colour. Seven of the filaments have fleſh-coloured anthers with a yellow pollen. Germ hirſute. Stigma blood-red. It flowers in march and april; and has little ſmell, but that unpleaſant.

77. Root branched. The whole plant is covered very cloſely with villoſe hairs, and has a ſtrong unpleaſant ſmell. Stem ſhrubby, branched, erect, round, knobbed, two feet high and more. Leaves alternate, three-lobed or five-lobed, bluntiſh, veined, thickiſh, three or four inches in length and breadth; petioles as long or longer, round, the thickneſs of a pigeon's quill and ſpreading. Stipules from a wider baſe lanceolate-acuminate, in a ſhort time becoming dry and of a ruſt-colour. Peduncles terminating, ſolitary, in pairs or threes, about three inches in length, the thickneſs, at moſt, of a pigeon's quill, almoſt erect or ſpreading a little. Leaflets of the involucre to the compound umbel ſeveral; to the ſimple and partial umbels commonly ſix, lanceolate, acute, ſpreading very much, green. Peduncles of the particular umbels about two inches long. Pedicels about ſix, an inch long, very ſhortly grooved, green, duſky purple above. Calycine leaflets lanceolate, acute, hirſute underneath and at the edges, ſlightly ſtriated, ſpreading very much; the upper one twice as wide as the reſt. Petals oblong, blunt, a little longer than the calyx, white with a little longitudinal red band at the claw; the two upper ones ſpreading very much and three times as wide as the three lower ones, which are extended downwards. Filaments blood-red, the length of the calyx. Anthers oblong, fleſh-coloured. Germ hirſute. Stigma blood-red. It flowers in april and the following months.

78. Root branched. The whole plant has a ſtrong ſmell. Stem ſhrubby, the thickneſs of a finger, round, irregular with projecting ſcars, erect, firm, branched, three feet high, when young hirſute, when old ſmooth and brown. Branches hirſute, pale green. Leaves ſcattered, roughiſh, wrinkled underneath, ſtiffiſh; the uppermoſt oppoſite: lobes ſharpiſh: petioles round, hirſute, commonly longer than the leaf. Stipules from a broad ſubcordate baſe acuminate or cuſped, hirſute, ciliate, ſpreading very much. Peduncles oppoſite to a leaf and axillary, hirſute, an inch or two in length, ſpreading. Umbel from five to ten-flowered, having the pedicels bent outwards. Leaflets of the involucre five or more, lanceolate, acuminate, hirſute, ciliate, ſpreading very much, green. Pedicels at moſt an inch long, grooved to the middle and jointed, hirſute, ſpreading very much, green. Calycine leaflets lanceolate, acute, half rolled back, hirſute, green; the upper one twice as wide as the reſt. Petals blunt, ſnow white without any ſpot; the two upper ones longer, three times as wide as the others, wedge-ſhaped, emarginate, half turned back; the three lower ſublinear, quite entire, ſtretched forwards. Filaments awl-ſhaped, erect, white, ſeven fertile. Anthers oblong, incumbent, orange-coloured. Stigma purple. Fruit hirſute. It flowers from june to auguſt, and has a ſtrong ſmell.

79. Stem three or four feet high, round, branched, browniſh, with aſh-coloured ſcars from the fallen leaves. Stipules acuminate, toothed, ſmooth, appearing in the magnifier ciliate along the edge, often as broad as they are long. Leaves alternate, except on the flowering branches, where they are commonly oppoſite, three-lobed or almoſt five-lobed, a little rough-haired only along the dorſal veins, which are very protuberant; the lower ones leſs deeply divided into rounder lobes, much larger and unſpotted, the others more deeply divided into oblong lobes, with a ferruginous or browniſh blood-red zone on the upper ſurface. Petioles round, rough, the lower ones twice as long as the leaf. Peduncles axillary, alternate, erect, ſomewhat rugged, the lower often oppoſite to a leaf. Leaflets of the involucre four or five, ovate, ciliate, caducous. Pedicels an inch long, rough, green, jointed about the

middle, and thence to the top thicker and grooved. Calycine leaflets lanceolate, rough, acuminate, ciliate, green; the four lower reflex, the upper one wider and erect. Petals blunt, spreading: the three lower oblong, shorter, pale rose colour; the two upper wedge-shaped, three times as wide as the lower ones, twice as long as the calyx, all over dark red, with longitudinal bands of a much darker red. Filaments short, seven of them fertile. Anthers oblong, yellow. Germ hirsute. Style somewhat hairy. Stigma villose, blood-red. It flowers here in the summer. The leaves have hardly any smell. The flowers have rather a disagreeable scent.

80. From a branched root arise very many weak stems, two feet high and more, round, smooth, almost upright, of a pale bay colour, irregular from the scars of fallen leaves. Stipules lanceolate-oblong, acuminate, smooth, ciliate with whitish soft prickles, dusky purple. Leaves mostly opposite, three or five-lobed, beneath along the principal veins a little rough-haired, green above, glaucous or sometimes purplish underneath: petioles very long, round, somewhat rugged, spreading out horizontally. The floral leaves are sessile. Peduncles alternate. Leaflets of the involucre four or five, lanceolate, acuminate, smooth, ciliate, purple. Pedicels purple, an inch and half long, smooth, jointed, from the joint to the top thicker and grooved. Calycine leaflets lanceolate, acuminate, ciliate, green, four of them reflex, the upper one erect and a little wider than the others. Petals wedge-shaped, blunt, pale rose-colour, spreading; the two upper ones emarginate, almost twice as wide as the three others, and having a red band below the middle. Anthers blood-red. Germ hirsute. Stigma villose above, blood-red. It flowers in summer, and has little smell.

81. Stem upright, three feet high, woody, very much branched, ferruginous, when young red, round, roughish, appearing rough-haired in the magnifier, the thickness of a finger at the base. Leaves alternate except the uppermost which are opposite, approximating, numerous, rigid, petioled: lobes thickish, pinnatifidly and acutely gashed, a little converging or somewhat cowled, about an inch and half in length. Stipules in pairs or threes, lanceolate, acuminate, somewhat rough-haired, spreading very much, brownish. Peduncles axillary, round, somewhat rough-haired, sustaining from one to three flowers. Leaflets of the involucre few, lanceolate, acute, villose, spreading very much, of the same colour with the stipules. Pedicels half an inch long, jointed above and thence very shortly grooved. Calycine leaflets lanceolate, acuminate, villose, spreading. Petals flesh-coloured, spreading very much; the two upper ones obovate, emarginate or quite entire, twice as wide as the three lower, which are oblong, narrow, blunt, quite entire. Seven filaments fertile. Anthers oblong, yellow. Germ ovate, hirsute. Style white. Stigma blood-red. It flowers in summer, and the whole plant has a balsamic scent approaching to that of Tacamahaca.

82. Stem four or five feet high, almost upright: branches rod-like, round, ferruginous: these with the leaves, stipules, peduncles, involucres and calyxes are very shortly rough-haired. Leaves closely distich or in two rows all along the branches, the upper ones converging, the lower spreading, alternate, rigid, thickish, on very short petioles, three-nerved, from a quite entire wedge-form base widening above into a rounded gash-toothed prickly-ciliate circumference; the largest scarcely an inch in length. In the axils of these there are two or more very small ones, from the middle of which a new branch frequently arises. Stipules two, cordate, acuminate, small, ciliate. Peduncles terminating, solitary, short, erect. Leaflets of the involucre five lanceolate, acute, almost upright, green. Pedicels scarcely an inch long, erect. Calycine leaflets lanceolate, acuminate, green; four of them reflex, the upper one erect and wider. Petals white or tinged with flesh-colour, twice as long as the calyx; the two upper ones spatulate, rounded at top, erect, with two parallel lines at the base; the three lower linear-oblong, bent forwards, three times narrower than the others. Filaments flesh-coloured, one-third shorter than the petals, seven fertile. Anthers vermilion. Germ silky. Style blood-red, hirsute. Stigma blood-red. Seed acuminate at the base, silky with a bearded awn. It has little smell. After flowering whilst the seeds are growing, young branches are pushed out beyond them, and the peduncles cease to be terminating.

It is easily distinguished from *P. crispum* by having no smell, or at most a slight smell of turpentine when bruised: the leaves are larger, always on very short petioles, of a true wedge shape, scarce obsolerely three-lobed, scarce curled, and the stature of the whole is much greater.]

PROPAGATION AND CULTURE.

All the sorts of Pelargonium or African Crane's-bill may be propagated by seeds; they may be sown upon a bed of light earth towards the end of march, where the plants will appear in a month or five weeks after, and by the beginning of june the plants will be fit to remove; when they should be carefully taken up, and each planted into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation till the plants have taken new root; then they may be removed into a sheltered situation, and placed among other of the hardier green-house plants, where they may remain till autumn, when they must be removed into the green-house, and treated in the same manner as other hardy kinds of green-house plants.

But those who are desirous to have their plants large, and flower soon, sow the seeds upon a moderate hot-bed in the spring, on which the plants will come up much sooner, and will be fit to remove long before those which are sown in the open air; but when these plants come up, there must be great care taken not to draw them up weak; and when they are transplanted, the pots should be plunged into another moderate hot-bed, observing to shade them from the sun till they have taken new root; then they must be gradually inured to bear the open air, into which they should be removed the beginning of june, and placed in a sheltered situation with other exotic plants. If these plants are brought forward in the spring, most of the sorts will flower the same summer, and the plants being strong before the winter, will make a better appearance in the green-house.

The shrubby African Geraniums are commonly propagated by cuttings, which, if planted in a shady border in june or july, will take good root in five or six weeks, and may then be taken up and planted into separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated in the same manner as the seedling plants. The seventeenth, nineteenth, twentieth, and thirty-fourth sorts, have more succulent stalks than the others, the cuttings therefore of these sorts should be planted in pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun in the heat of the day, and have but little water; for these are very apt to rot with much moisture. When these are well rooted, they may be separated and planted in pots filled with the same sort of earth, and placed in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till autumn. These four sorts should be sparingly watered, but especially in the winter, for they are apt to take a mouldiness with moisture, or in a damp air: they will thrive much better in an airy glass-case than in a green-house, because in the former they will have more sun and air than in the latter. But all the other shrubby sorts are proper furniture for the green-house, where they will only require protection from frost, but should have a large share of free air when the weather is mild, they will require water every week, in mild weather once or twice, but it should not be given them in too great plenty, especially in frosty weather. These plants should be hardened in the spring gradually, and towards the middle or end of may, they may be taken out of the green-house, and at first placed under the shelter of trees, where they may remain a fortnight or three weeks to harden;

harden; then ſhould be removed into a ſituation where they may be defended from ſtrong winds, and enjoy the morning ſun till eleven o'clock, where they will thrive better than in a warmer ſituation.

As theſe ſhrubby ſorts grow pretty faſt, they ſoon fill the pots with their roots; and if they ſtand long unremoved in ſummer, they frequently put out their roots through the holes at the bottom of the pots into the ground, and then the plants will grow vigorouſly; but when they are ſuffered to grow long in this manner, it will be difficult to remove them, for if their roots are torn off, all the younger branches will decay, and many times the plants are killed. Therefore the pots ſhould be moved once in a fortnight or three weeks, in the ſummer months, and the roots which may be then puſhing through the holes in the pots cut off, to prevent their ſtriking into the ground.

Theſe plants will alſo require to be new potted at leaſt twice in the ſummer; the firſt time ſhould be after they have been three weeks or a month out of the green-houſe; the ſecond ſhould be towards the end of auguſt, or the beginning of ſeptember, that the plants may have time to eſtabliſh their new roots before they are removed into the green-houſe.

When theſe are new potted, all the roots on the outſide of the balls of earth ſhould be carefully pared off, and as much of the old earth drawn away from the roots, as can be done with ſafety to the plants; then if they require it, they ſhould be put into pots a ſize larger than thoſe out of which they were taken, putting a quantity of freſh earth into the bottom of the pot; then place the plants upon that, being careful the ball about the roots of the plant is not ſo high as the rim of the pot, that ſome room may be left to contain the water which may be given to the plants. Then the cavity all round the ball ſhould be filled up with freſh earth, which ſhould be gently preſſed down, and the bottom of the pot beaten upon the ground, to ſettle down the earth; then the plant ſhould be well watered, and the ſtem faſtened to a rail, to prevent the wind from diſplacing the roots before they are fixed in the new earth.

The compoſt in which theſe plants thrive beſt (where there is not a conveniency of getting ſome good kitchen garden earth) is freſh hazel loam from a paſture, mixed with a fourth or fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is preferable to dung; but if it is light and warm, then a mixture of neat's-dung is beſt: this compoſt ſhould be mixed three or four months before it is uſed, and ſhould be turned over three or four times, that the parts may be well mixed and incorporated; but where a quantity of good kitchen-garden earth can be had, which has been well worked, and is clean from the roots of bad weeds, there will need no compoſition, for in that they will thrive full as well as in any mixture which can be made for them, eſpecially if the earth has lain in a heap for ſome time, and has been two or three times turned over to break the clods, and make it fine: theſe plants ſhould not be planted in very rich earth, for that will cauſe them to grow very luxuriant, but they will not flower ſo well as in a poorer ſoil.

The ſhrubby ſorts muſt be looked over frequently during the winter, whilſt they are in the green-houſe, to pick off all decayed leaves from them, which, if left on, will not only render the plants unſightly, but by their falling off, will make a litter among the other plants; and if they are ſuffered to rot in the houſe, they will occaſion a foul, naſty, damp air, which will be very prejudicial to all the plants; therefore to avoid this, they ſhould be conſtantly picked off every week; and during the ſummer ſeaſon, they will require to be picked every fortnight or three weeks to keep them clean from dead leaves; for as the branches advance, and new leaves are produced on their tops, the under ones as conſtantly decay; and if left on till they drop off, will render the plants very unſightly.

The ſpecies of the two firſt diviſions are generally increaſed by parting the roots in auguſt. Every tuber will grow, if it has a bud or eye to it. They may be planted in the ſame ſort of earth as was before directed; and if the pots are plunged into an old tan-bed, under a good frame in winter, the plants will thrive better than in a green-houſe: the glaſſes may be drawn off every day in mild weather; and if in ſevere froſt the glaſſes are well covered, it is all the ſhelter they require: they ſhould have little wet in winter, and therefore the glaſſes ſhould be kept over them in heavy rains, or in mild weather raiſed only at the top. They may alſo be propagated by ſeeds.

8. This having herbaceous ſtalks is beſt propagated by ſeeds. The cuttings indeed will take root, but ſeedling plants are preferable. Where the ſeeds of this, and many other ſorts are permitted to ſcatter, there will be a ſupply of young plants the ſpring following, provided the ſeeds are not buried too deep in the ground.

9. This may be propagated by ſeeds, or from heads ſlipped off from the ſhort fleſhy ſtalk: theſe heads ſhould have their lower leaves ſtripped off, and then be planted ſingle in a ſmall pot; or if the heads are ſmall, two or three may be put into one pot. Plunge them into a very moderate hot-bed, ſhade them, and refreſh them gently with water; they will take root in a month or five weeks; then harden them gradually to the open air, where they may remain till autumn, when they muſt be removed into ſhelter for the winter ſeaſon.

10. Sow the ſeeds on a moderate hot-bed or on an open bed of light earth in the ſpring. The latter will require only to be kept clean from weeds, and to be thinned where they are too cloſe; they will flower in july and auguſt, and if the autumn prove favourable, the ſeeds will ripen in ſeptember. Thoſe which were raiſed on the hot-bed will come earlier to flower, and more certainly perfect ſeeds. Some of theſe plants put into pots, plunged into an old tan-bed under a frame, and treated as directed for the tuberous-rooted ſorts, may be preſerved through the winter.

14. Being an annual plant, is propagated by ſeeds, ſown on a gentle hot-bed in the ſpring. When the plants are ſtrong enough to remove, plant each in a ſeparate ſmall pot, plunged into a moderate hot-bed, ſhaded, and gradually hardened to the open air, into which they may be removed in june: when the plants have filled the pots with their roots, ſhake them out, preſerving a ball of earth to their roots, and put them into pots a ſize larger: in theſe they will flower and ripen ſeeds, ſoon after which the plants will decay.

[18. This may be increaſed both by ſeeds and cuttings, but is found to be more tender than many other ſorts, and more liable to be injured by damps.

23. Readily increaſed by cuttings.

31. This is not diſpoſed to ripen its ſeeds, nor is it very readily increaſed by cuttings.

34. Readily propagated by cuttings, and ſometimes raiſed from ſeeds.

38. Readily ſtrikes from cuttings.

39. In favourable ſeaſons produces ſeeds, but is more uſually increaſed by cuttings.

40. 47. Readily propagated by cuttings.

48. This ſpecies rarely ripens its ſeeds with us, and is therefore uſually raiſed from cuttings, which are not very free in ſtriking.

55. Raiſed from cuttings without difficulty.

56. Moſt of the branches in this ſpecies running out ſpeedily into flowering ſtalks, form few proper for cuttings, and theſe are ſtruck with difficulty. Perfect ſeeds are produced ſparingly[1].

Stem-leaves quinate-pinnate linear somewhat fleshy.]

DESCRIPTIONS, *&c.*

1. This is a biennial plant, and generally dies soon after the seeds are perfected. It rises with an upright branching stalk about a foot high. Leaves heart-shaped, smooth. White flowers terminate the stalk in form of umbels. [Silicle obovate or orbiculate-pedunculed, not emarginate, leafy-compressed, coriaceous, somewhat rigid, netted-veined, smooth, valveless, and not divisible into regular valves with a knife. Seeds one to three, seldom more, ovate-reniform, compressed a little, ferruginous, supported by capillary threads proceeding from each edge of the silicle and verging towards the centre [k].

Native of Austria. Cultivated in 1768 by Mr. Miller. It flowers in may [l].

2. Stem upright, branched, round, even, a foot high, leafy. Leaves alternate, pinnate; segments five, linear, smooth, acute. Racemes long, with the pedunculs and calyxes scarcely pubescent. Petals white, subemarginate, four times as big as the calyx, spreading, sessile. Silicle roundish or ovate, entire, with the partition parallel. Seeds in the centre as in *Clypeola*, solitary in each cell, compressed.—Native of the Cape of Good Hope [m].]

PROPAGATION AND CULTURE.

1. This is easily propagated by seeds, which ripen in july, and may be sown in small patches in the borders of the flower-garden at the beginning of april. When the plants are up, leave four or five in each patch; pulling the others out, to give these room to grow. Keep them clean from weeds.

P. Myrtilloides. *Thunb. prodr.* 30.
Leaves lanceolate.

DESCRIPTIONS, *&c.*

These are shrubs, rugged below with the vestiges of fallen leaves, leafy above; leaves opposite cross-wise, sessile, approximating imbricately in a fourfold row, the upper ones near the flowers like scales and coloured, whence the calyx in some species is as it were many-leaved and imbricated; flowers terminating, sessile, solitary or several heaped together; fruit as in the order of *Acanthi*, but four-celled. Perhaps this genus may be allied to them, but having been hitherto little examined except in dried specimens, the natural order of the genus *Penæa* must yet remain uncertain [n].

1. Leaves blumtish. Corollas blunt. Calyx to the middle flower none. Style more awl-shaped than in the rest.

2. Flowers red. Style four-cornered [o]. Leaves on the stems and branches frequent, sessile. Flowers at the ends of the branches, heaped together [p].—Introduced in 1787, by Masson [q].

3. This is a stiff shrub, with the branches commonly in threes. Leaves opposite or in threes, subsessile, bluntish, shining, with the edge curved back, the size of Box-leaves. Flowers among the leaves, subsessile, not longer than the leaves, white [r].

4. Stems red, with elongated branches. Leaves sessile, exactly ovate, even, sharpish, quite entire, al-

[k] Gærtner. [l] Hort. kew. [m] Linn. suppl.
[n] Juss. gen. [o] Linn. spec. & syst. [p] Ray.
[q] Hort. kew. [r] Linn. mant.

moſt keeled under the baſe, longer than the interſtices. Flowers in the axils of the leaves, yellow, the length of the leaves. Calyx four-leaved, yellow, ſcariole, the length of the leaves. Segments of the corolla lanceolate, three-ſided or keeled within, the keel cut out at the baſe. Filaments none. Anthers in the throat of the corolla. Stigma blunt, four-cornered [1].

Willdenow doubts whether this be diſtinct from the preceding.

5. Of this we have no deſcription.

6. Branches very numerous, round; branchlets angular. Leaves ovate, narrower at the baſe, acute, ſpreading, even. Flowers purple, in terminating bundles. Bractes ſmaller than the leaf, purple.

7. Leaves even, with a longitudinal line, ſubglandular at the tip. Bractes of the ſpike, twice as broad as the leaf, ciliate, reſinous and unctuous. Corollas rather large [2].—Introduced in 1787, by Maſſon [3].

8. This is a little ſhrub with round branches. Leaves ſubpetioled, oval or ſomewhat oblong, thickiſh, veinleſs, remote. Floral leaves ſmall, rhomb-orbiculate, or orbiculate-acute. Flowers at the ends of the branches, ſubſolitary, on very ſhort peduncles, ſharpiſh.

9. Branches upright round red. Leaves ſeſſile cluſtered even, like thoſe of *Myrtus tarentina*, ſcarcely nerved underneath. Flowers terminating, ſubſolitary, ſurrounded by ſharp green bractes, under which are two ſmall leaves. Calyx acute, green, not at all coloured [4].

All theſe ſhrubs are natives of the Cape of Good Hope. Loureiro has added two ſpecies, natives of Cochinchina: Penæa nitida, which he thinks is allied Linnæus's P. Myrtoides; and Penæa ſcandens to P. marginata. He allows that they are not conformable to Linnæus's generic character: and indeed they certainly belong to another genus.

Leaves baſtate-lanceolate ſerrate.

DESCRIPTION, &c.

1. This is an annual plant which dies in the autumn, ſoon after it has ripened the ſeeds. It has an upright ſtalk from two to near three feet high, ſending out ſide branches the whole length; thoſe from the lower part of the ſtalks are the longeſt, the others gradually diminiſh, ſo as to form a ſort of pyramid. They are garniſhed with leaves of different forms; the lower leaves, which are largeſt, are cut on their ſides towards the baſe into two ſide lobes which are ſhort, and the middle is extended two or three inches farther in length, ſo that the leaves greatly reſemble the points of halberts in their ſhape; they are ſlightly ſerrate, and of a lucid green on their upper ſide, but paler on their under, ſtanding upon pretty long foot-ſtalks. The leaves which are on the upper part of the branches are much narrower, and ſome of them have very ſmall indentures on their ſides; they ſit cloſer to the ſtalks, and are placed alternately. The flowers are axillary; they come out for the moſt part ſingly, but ſometimes there are two ariſing at the ſame place from the ſide of the foot-ſtalk of the leaves. The peduncle is ſhort and ſlender. The flower is of one petal, cut into five obtuſe ſegments almoſt to the bottom, but as they are joined and fall off in one piece, the flower is monopetalous, according to Ray and Tournefort: [but Linneus makes it pentapetalous.] It is of a fine ſcarlet colour; appears in July, and the ſeeds ripen in the autumn.

Native of India, whence Mr. Miller received the ſeeds ſeveral times. [But it was cultivated at Hampton Court in 1690 [7].

It is alſo a native of Japan, according to Thunberg, and is cultivated both in China and Cochinchina according to Loureiro.

Linneus deſcribes the cotyledons as two-parted; the peduncles as axillary and twin; the involucre as one-flowered, three-leaved and deciduous; the flowers drooping; the ſtamens as fifteen, and between each three a caſtrated filament, the length of the corolla, petaloid and coloured.

[1] Linn. ſuppl. [2] Linn. mant. [3] Hort. kew. [4] Linn. ſuppl.

[7] Hort. kew.

Loureiro remarks, in correſpondence with the generic character as given above, that the five leaflets of the nectary are improperly called caſtrated filaments, being ſo different from them in ſize, figure and ſituation. He regards the tubular, five-cornered body on which the ſtamens are placed rather as the nectary, than as the coaleſcent filaments.

He deſcribes the ſtem as five feet high, upright, round, ſtraight, with few aſcending branches; the leaves as cared-haſtate at the baſe, thence awl-ſhaped and ſerrate; alternate, on ſhort petioles; the flowers as ſolitary, expanding at noon, and falling in the evening. Calyx inferior, five-leaved, ſpreading, permanent: leaflets lanceolate, curved in, ciliate-hairy, with a reflex acuminate point. Petals blunt, ſubequilateral, ſpreading out very much in a wheel-ſhape. Nectary tubular, five-cornered, ſhort, ſupporting five, lanceolate, erect, concolor leaflets. Filaments awl-ſhaped, placed on the nectary, ſhorter than the leaflets of it, and deciduous with it. Style turbinate-linear, five-cornered, equal to the petals. Stigma ſimple. Capſule ovate. Seeds in a double row, angular towards the centre, convex outwardly.]

PROPAGATION AND CULTURE.

1. The ſeeds of this plant muſt be ſown upon a good hot-bed early in march, and when the plants are fit to tranſplant, there ſhould be a new hot-bed prepared to receive them, into which ſhould be plunged ſome ſmall pots filled with good kitchen-garden earth; in each of theſe ſhould be one plant put, giving them a little water to ſettle the earth to their roots; they muſt alſo be ſhaded from the ſun till they have taken new root, then they ſhould be treated in the ſame way as other tender exotic plants, admitting the free air to them every day in proportion to the warmth of the ſeaſon, and covering the glaſſes with mats every evening to keep them warm. When the plants are advanced in their growth ſo as to fill the pots with their roots, they ſhould be ſhifted into larger pots, filled with the ſame ſort of earth as before, and plunged into another hot-bed, where they may remain as long as they can ſtand under the glaſſes of the bed without being injured; and afterwards they muſt be removed either into a ſtove or a glaſs-caſe, where they may be ſcreened from the cold, and in warm weather have plenty of freſh air admitted to them. With this management the plants will begin to flower early in july, and there will be a ſucceſſion of flowers continued till the end of ſeptember, during which time they will make a good appearance. The ſeeds ripen gradually after each other in the ſame ſucceſſion as the flowers were produced, ſo they ſhould be gathered as ſoon as their capſules begin to open at the top.

Theſe plants are ſometimes turned out of the pots, when they are ſtrong, and planted in warm borders, where, if the ſeaſon prove very warm, the plants will flower pretty well; but theſe very rarely perfect their ſeeds.

DESCRIPTION, *&c.*

Stalks about a foot high. Leaves oblong, alternate, Flowers greeniſh-yellow in terminating cluſters, making little appearance. [Stem herbaceous, diffuſed or ſtraight, angular; the angles rugged. Branches alternate, like the ſtem. Leaves alternate, ſubpetioled, ſerrate, ſcarcely fleſhy, green on both ſides. Peduncle terminating with a few revolute ſpikes. Flowers alternate, pedicelled, aſcending. The ſegments of the calyx for the moſt part alternately larger and ſmaller. Anthers red. Styles none [a]. Capſule undivided, compoſed of five partial capſules, ventricoſe at bottom, rounded-five-cornered, ſtarred at top, five-beaked, opening five ways between the beaks: beaks filiform, ſhort, conical at the baſe, with a ſmall head at top, ſpreading out horizontally. Partitions ſimple, faſtened to the axis and grooves of the valves. Seeds irregular like ſawduſt, or linear acuminate, ſhagreened with raiſed dots, ruſcent, faſtened to the partitions on every ſide [b].

Native of Virginia. Biennial, according to Miller, who cultivated it in 1768 [c]. Others reckon it to be perennial.] It flowers at the end of july, and the ſeeds ripen in the autumn.

[PENTSTEMON. (*So named from the flower having a fifth imperfect ſtamen.*)

Lin. gen. Schreb. n. 1758. *p.* 808. *Mitchell in act. nat. cur.* 8. *app.* 214. *Ait. hort. kew.* 3. 511.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, permanent: *ſegments* lanceolate, almoſt equal.

COR. one-petalled, two-lipped: *tube* longer than the calyx, gibbous above at the baſe, wider at top, and there ventricoſe underneath: *upper lip* upright bifid; *ſegments* ovate, blunt, ſhorter than the lower lip: *lower lip* three-parted; *ſegments* ovate, blunt, bent down, ſhorter than the tube.

STAM. *Filaments* four, filiform, diverging at the tip, inſerted into the baſe of the tube, and ſhorter than it; the two lower longer. *Anthers* roundiſh, diſtant, included, bifid; with the lobes divaricating.

The *Rudiment* of a fifth filament between the upper ones inſerted into the tube, the ſame length with the ſtamens, filiform, ſtraight, bearded above at the tip.

PIST. *Germ* ovate. *Style* filiform, the length of the tube, bent down at the tip. *Stigma* truncate.

PER. *Capſule* ovate, acute, compreſſed, two-celled, two-valved.

SEEDS numerous, ſubglobular. *Receptacle* large.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* bilabiate, ventricoſe. *Rudiment* of a fifth ſtamen bearded above. *Capſ.* two-celled.

DESCRIPTIONS, &c.

1. This is an annual creeping plant. Stems numerous, branched, dichotomous, from half a foot or a ſpan to a foot in length, ſmooth, angular, jointed, of a reddiſh colour. Leaves oppoſite, obovate, orbiculate or ſpatulate tapering into the petiole, ſmooth, quite entire. Flowers very ſmall, ſolitary, oppoſite, ſeſſile. Corolla and filaments pinky red. Petals deciduous, regularly ſix, but more frequently one, two or three, and ſometimes none. Calyx greeniſh white, ſmooth, angular-plaited, ſtriated. Anthers dark coloured. Stigma white [a]. Capſule ſmall, globular, membranaceous, very thin, knobbed on account of the protuberant ſeeds, valveleſs; partition membranaceous, correſponding with the external groove of the capſule. Receptacle fleſhy, roundiſh, compreſſed a little, faſtened to the partition on both ſides. Seeds about thirty in each cell, obovate acuminate, convex on one ſide, flat on the other, pale [b].

Native of many parts of Europe, in bogs, marſhes, ditches, and eſpecially where water has ſtagnated in winter and becomes dry in ſummer. It flowers from july to ſeptember.

2. Calyx bell-ſhaped, with the border eight-cleft. Corolla tubular, with the border four-parted. Stamens four. Germ growing to the tube of the calyx. Stigmas two. Capſule inferior, two-celled, crowned [c].

According to Juſſieu, the corolla is monopetalous, four-ſtamened, the germ inferior, the ſtigma double; the capſule two-celled, two-valved, many-ſeeded; with a ſtipule between the leaves: it is therefore more nearly allied to the *Rubiaceæ*, and particularly to *Oldenlandia* or *Gonozia*; but it is diſtinguiſhed from them by its eight-toothed calyx.

In the opinion of Swartz, the corolla, fruit, number and habit do not admit of its ranging with *Peplis*. It ſeems rather to be a *Hedyotis*, and differs little in appearance from *H. pumila*. He thus deſcribes it—The root conſiſts of globular diſtinct tubers. Stem ſubdivided, divaricated, round. Stipules ſmall, ſheathing, acuminate. Leaves ſubſeſſile, the upper ones in fours, ovate-cordate, ſubſpatulate, entire, ſomewhat hiſpid above, ſmooth beneath. Flowers terminating, peduncled, the ſize of a pin's head. Peduncles ſhort, one-flowered. Perianth four or five-cleft, ſuperior: ſegments biſid, ſo that it ſeems to be eight or ten-toothed, permanent. Corolla one-petalled, ovate, ſcarcely longer than the calyx, four-parted; ſegments blunt, upright. Filaments four, awl-ſhaped, ſhorter than the corolla. Anthers ovate, ſmall, concealed by the diviſions of the corolla. Germ twin. Style cloven almoſt to the baſe. Stigmas awl ſhaped. Capſule twin, globular, two-celled, ſurrounded and crowned by the calyx, opening at top by four valves. Seeds two in each cell, orbiculate covered by the valves. It is an annual plant, native of the Weſt Indies, in dry ſhady places at the foot of mountains and trees.

GENERIC CHARACTER.

CAL. *Common* oblong, imbricate: *leaflets* lanceolate, the inner ones ſcarcely longer than the corolla.
COR. *Compound* imbricate, rayed: *corollets* hermaphrodite in the diſk; female in the ray.

[a] Krocker, Withering. Lyons M.S. in Relh.
[b] Gærtner.
[c] Linn. ſyſt.

[a] Ardaini.

Proper of the hermaphrodite tubular, semibifid: *inner lip* two-parted, acuminate, equal; *outer* semitrifid, linear, equal: of the female linear, ligulate, three-toothed, two-toothed within at the base.

STAM. in the hermaphrodites: *Filaments* five, short. *Anther* cylindric, tubular, five-toothed.

PIST. in the hermaphrodites: *Germ* small. *Style* simple. *Stigma* bifid, blunt. In the females—*Germ* small. *Style* semibifid. *Stigmas* blunt.

PER. none. *Calyx* unchanged.

SEEDS solitary, obovate. *Down* capillary, sessile, very copious, the length of the calyx, fastigiate.

REC. naked.

OBS. *The flower resembles a semifloscular corolla though it is really rayed.*

The character is taken from P. semifloscular, *which is very distinct in the genus.*

P. radiale *agrees with the genus in its bilabiate capsules, but differs in the whole habit.*

P. brasiliense *has subradiate flowers, and hermaphrodite bilabiate florets in the disk and ray.*

ESSENTIAL CHARACTER.

Corollets bilabiate. *Down* simple. *Recept.* naked.

SPECIES.

1. Perdicium semifloscular.
Lin. spec. 1248. *syst.* 769. *Reich.* 3. 836. *amoen.* 6. *asr.* 72.
Flower semifloscular, scape one-flowered naked.

Lin. spec. 1248. *syst.* 769. *Reich.* 3. 837.
Inula Trixis. *Lin. amoen.* 5. 406.
Trixis frutescens, &c. *Brown. jam.* 312. *t.* 33. *f.* 1.
Flowers subradiate, outer calyx four-leaved, stem shrubby.

3. Perdicium brasiliense.
Lin. mant. 115. *syst.* 769. *Reich.* 3. 837.
Flowers subradiate, calyxes simple, stem herbaceous.

4. Perdicium magellanicum.
Lin. suppl. 376. *syst.* 769.
Leaves runcinate, stem two-leaved simple one-flowered.

5. Perdicium tomentosum.
Vahl. jap. 319. *Lin. syst.* 769.
Leaves lyrate tomentose underneath.

6. Perdicium lævigatum.
Gærtn. fruct. 2. 450. *Berg. act. holm.* 1772. 236. *t.* 7.
Flowers subradiate, stem suffruticose, leaves lanceolate acute quite entire.

DESCRIPTIONS, &c.

1. Root fibrous. Stature of *Leontodon*. Root-leaves of *Taraxacum*, naked. Scape the length of the leaves. Flower the size of *Leontodon*. Calyx of *Scorzonera*. Corolla rayed. Corollets between those of semifloscular and radial flowers, semibifid, with the inner lip two-parted, the outer three-parted. Down simple. Receptacle naked.—Native of the Cape of Good Hope [a].

2. Habit of the flowers as in *Inula* or *Conyza*. These two species differ in their whole appearance, and are scarcely allied; but the singular division of the corollets, in the outer segments smoother, almost as in *Elephantopus*, made Linnæus unite them, till they were examined more carefully in a living state [b].

Browne, who calls it shrubby Trixis, says that this little shrub is very common in the savannas about Kingston in Jamaica, and seldom rises above four or five feet in height. The common receptacles are disposed at the extremities of the branches, and the outer divisions of the flowers grow gradually smaller, and curl more downwards as they approach the centre; which gives the whole something the appearance of a radiated flower, at the first appearance.

3. Root-leaves lanceolate-ovate, repand-toothed, subpubescent, viscid. Stem-leaves alternate, sessile, lanceolate, narrow, somewhat toothed. Flowers at the top of the stem, naked, several. They have the appearance of *Arnica montana*, with the proper peduncles elongated and submonophyllous. Calyx twelve to sixteen-leaved; the leaflets lanceolate, blunt, equal. Corolla yellow. Florets both in the disk and ray bilabiate hermaphrodite.—Native of Brasil [c].

4. This is a pretty little plant. Leaves small, radical, several, runcinate-pinnatifid, and ciliate on the rachis, whence they are scabrous. Stem quite simple, tomentose, with two alternate serrate leaves. Flower white, rayed.—Native of Terra del Fuego [d].

5. This is a small, stemless, herbaceous plant. Leaves radical, several, petioled, erect, a finger's length; lobes toothed, the end tooth rounded. Scape tomentose, erect, one-flowered, a little longer than the leaves. Calyx many-leaved, imbricate, smooth. Flowers with a purple ray. Corollets of the disk yellow, four-cleft; one segment longer, linear, more deeply divided from the rest; the two lateral ones similar and equal; the middle one wider, rounded, scarcely longer than the lateral ones. Down simple.—Native of Japan; flowering there in april and may [e].

6. Calyx cylindric, consisting of eight equal leaves in one row; besides which it has often at the base two or four similar leaflets, a little longer than the others. All the florets androgynous, bilabiate, fertile; in the *disk* four or five, tubular, bifid at top, with the lips equal, concave, quite entire, villose on the outside; in the *ray* eight, unequally bilabiate; the outer lip ovate-oblong, with two or three teeth, and rayed; inner lip linear, quite entire, rolled back at the tip. Receptacle narrow, flat, densely and very shortly villose. Seeds uniform, oblong, obsoletely angular, with very minute bristles scattered over them, bay-coloured. Down bristle-shaped, with very many toothlets, twice as long as the seed. This differs from the others in the shape of the florets [f].

Stem round, smooth, ash-coloured, naked, striated, with warted scars: branches greenish, smooth, leafy at top, alternate, spreading out at a right angle. Leaves alternate, on short petioles, an inch long, smooth on both sides, ciliate, spreading. Stipules none, but a callus, from which the petiole springs, is permanent. Flowers two or three, often five, terminating; on smooth capillary divaricating peduncles. Bractes spatulate, acute, smooth, solitary; but near the calyx two or three together [g].

Class. 5. 2. Pentandria Digynia—potius Gynandria.
Nat. order of *Contortæ. Apocineæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, upright, acute, permanent.

COR. one-petalled, salver-shaped: *tube* cylindrical, longer than the calyx: *border* five-parted, flat, with oblong segments.

Nectaries five, semisagittate, erect, compressed, attenuated into a dagger point, curved inwards, with a nodding tooth at the outer base.

STAM. *Filaments* — —. *Anthers* two to each gland, curved upwards, divaricating, obovate, pellucid, yellow, with scarcely any discernible pollen. *Stn. Tubercles* (glands) five, immersed in the stigma.

PIST. *Germs* two, ovate, acuminate. *Styles* none, (two, very short, united, villose. *Stigmas* obsolete. *Stn.*)

PER. *Follicles* two.

SEED — —

OBS. *Allied to* Periploca græca.—*The character wants correction.* S. and Juss.—*See description of* P. odoratissima *by Smith.*

ESSENTIAL CHARACTER.

Contorted. Nectary surrounding the genitals with five sagittated cusps. *Cor.* salver-shaped.

[a] Linn. amoen. & spec. [b] Linn. spec. [c] Linn. mant. [d] Linn. suppl. [e] Thunberg. [f] Gærtner. [g] Bergius.

5. Pergularia japonica.
Thunb. jap. 111. *Lin. fyſt.* 256. *ſpec. Willd.* 1248.
Leaves heart-ſhaped ſmooth, ſegments of the corolla ovate villoſe within, umbels ſimple.

DESCRIPTIONS, &c.

1. Stem twining, even. Leaves oppoſite, petioled, quite entire. Peduncles axillary, ſubdivided, alternate. Native of the Eaſt Indies [p].

2. The ſtem of this is alſo twining, but herbaceous, whereas in the preceding it is ſhrubby.—Native of the Cape of Good Hope.

3. Root branched, much ſpreading, whitiſh. Stem ſhrubby, twining, branched, round; its bark aſh-coloured, ſpongy, full of longitudinal fiſſures; branches nearly oppoſite, very long, flaccid, moſtly ſimple, round, brown, downy, leafy. Leaves oppoſite, ſpreading and bent downwards, pointed, entire, ſlightly concave, opaque, veiny, downy on the veins and margin, paler beneath: footſtalks one fourth of the length of the leaves, round, downy, with a furrow along the upper ſide, furniſhed at the baſe on each ſide and at the top with two or three acute brown-tipped glands. Stipules none. Panicles axillary, ſolitary, on longiſh flower-ſtalks, dichotomous, ſomewhat corymboſe, many-flowered, downy: general flower-ſtalks round; partial ſlightly angular. Bractes ſolitary at each diviſion of the panicle, lanceolate, obtuſe, brown on the back and at the tip. Flowers the ſize of a Primroſe, yelloviſh green, with a ſweet lemon-like ſmell, eſpecially in an evening. Calyx bell-ſhaped, deeply five-cleft; ſegments lanceolate, veined, ſlightly downy, minutely ciliated, tipped with brown. Tube of the corolla a little longer than the calyx, ſlightly downy, ſtriped; inflated, and with five ſwellings in the baſe; having a pervious orifice, ſet with numerous hairs pointing backwards. Border ſpreading, five-cleft; ſegments the length of the tube, obtuſe, ſmooth, ciliated, oblique, their margin turned down, the under ſide paleſt. Outer nectary half as long as the tube, green, conſiſting of five triangular bodies, ſomewhat arrow-ſhaped at their baſe; concave behind, and with two notches in the upper part; keel-ſhaped within; their ſummits pointed, bent in, thin, white, and ſticking together: inner nectary ſomewhat ſhorter, of five membranous leaves, dilated at the baſe, hollowed at the back, united by their ſides, attached together by their pointed membranous tips, embracing the organs of fructification, and on their inſide towards the top having two yellow membranous hoods, connected by their backs, formed to embrace the anthers in their natural ſituation. Column of the fructification rather ſhorter than the nectaries. Germs ſuperior, diſtinct but cloſe together, ſmall, ſmooth, green, ſurrounded at the baſe with a ſingle row of numerous, probably nectariferous glands. Styles terminating in one denſely villoſe, conical, obtuſe (not truncated) body; on the ſides of which ſtand five glands, alternate with the portions of the nectary, dark purple, with one anther on each ſide.

In the natural order to which this plant belongs the eſſential parts of fructification are more than commonly obſcure. It ſeems to be of the claſs Gynandria, as perhaps are all the true *Contortæ*, whoſe anthers have a great affinity, in appearance as well as ſtructure, with thoſe of the Orchis tribe.

Its native place is uncertain; but it is cultivated in China, whence Lady Hume received the plant. It flowered in her ſtove in auguſt 1791.

A variety of this, with ſomewhat rounder leaves, and more tawny flowers, is cultivated for its agreeable fragrance in the gardens of the Eaſt Indies, and is commonly called there *Weſt Coaſt Creeper*. It was brought to the Kew garden about the ſame time that Lady Hume had the Chineſe plant. The ſpecimen in the Linnean herbarium is from China, whence it appears to have been brought to the Upſal garden; and to this belongs the deſcription in the Mantiſſa, where the leaves are, not much amiſs, deſcribed as ſmooth: but the ſpecific character and place of growth relate to a widely different plant, *Aſclepias cordata* of Forſkall (*Vahl. ſymb.* 1. 23.) the leaves of which are clothed with extremely thick down (as in the Bankſian herbarium); and it appears from Forſkall's deſcription, (*Flora Ægypt. Arab.* 49.) that the ſtructure of its flowers perfectly agrees with the Aſclepias [s].

4. Branches twining, ſlender, aſh-coloured, appearing villoſe when examined by a glaſs. Leaves oppoſite, nerved and veined, two inches long; the upper one leſs. Petiole the length of the leaves. Umbels lateral, peduncle, ſhorter than the leaves. Peduncle thicker than the petiole, rigid. Pedicels filiform, pubeſcent like the calyxes. Corollas funnel-form: throat villoſe; ſometimes alſo the border is a little villoſe. It is allied to *P. japonica*, but the umbels are proliferous, not ſimple; the ſegments alſo of the border are linear, not ovate: ſtill it may be doubted whether they be actually diſtinct.—Native of the Eaſt Indies and of China [t].

5. Stem twining, round, ſmooth, ſimple. Leaves oppoſite, acute, quite entire, nerved, ſpreading, an inch long, on round, ſmooth petioles. Flowers axillary, peduncled, erect. Calyx parted almoſt to the baſe, ſhorter than the corolla; the parts lanceolate, rough-haired. Tube of the corolla bell-ſhaped, a little ſhorter than the calyx: ſegments of the border blunt, ſpreading and bent back, ſmooth on the outſide but villoſe within. Nectaries ſubſagittate, connate with the anthers into a cylinder, and alſo with the ſtigma. Filaments ſcarcely any. Anthers connate with the nectary into a cylinder, and together covering the other parts of fructification. Germs upright, ſmooth, the length of the calyx. Styles none, except the elongation of the germs. Stigma covering the piſtils, connate with the ſummits of the nectary, terminating in a long upright thread, attenuated at the tip, flexuoſe, white, the length of the corolla. The reſt as in the generic character.—Native of Japan, where it flowers in auguſt [u].

Loureiro has two ſpecies, both natives of China, which he names *divaricata* and *ſinenſis*. He remarks, that in all the ſpecies of Pergularia and Apocynum which he had ſeen, the flowers have one piſtil only.

Lin. ſyſt. 533. *Reich.* 3. 47. *gen.* 578.
Meliſſa maxima. *Arduini animadv.* 2. 28. *t.* 13.

DESCRIPTION, *&c.*

Stem ſimple, ſtiff, blunt, quadrangular, rough-haired. Leaves ovate, almoſt naked, ſerrate; on petioles the length of the leaves. Racemes lateral and terminating, rough-haired, upright. Flowers ſmall, white, ſolitary or by threes, rough-haired in the calyx, with leafy bractes longer than the flower.

It is an annual plant, native of the Eaſt Indies[a].

Leaves oblong-cordate pubeſcent, flowers axillary, ſtem ſhrubby climbing.

DESCRIPTIONS, *&c.*

1. Stems ſhrubby twining round any ſupport more than forty feet in height, covered with a dark bark, and ſending out ſlender branches which twine round each other. Leaves ovate-lanceolate, near four inches long, and two broad in the middle, of a lucid green on their upper ſide, but pale on their under, oppoſite, on ſhort foot-ſtalks. The flowers come out towards the ends of the ſmall branches in bunches, and are of a purple colour.

[Jacquin, in his miſcellanies, has given a very particular and accurate deſcription, accompanied with figures, of the extraordinary ſtructure of the flower, in this ſpecies and *africana*, n. 9.—Native of Syria. Cultivated by Gerarde in 1597[a]. "My loving friend," ſays he, "John Robin, herbariſt in Paris, did ſend me plants for my garden, where they flower and flouriſh." He calls it *Cuming Dog's bane.*]

It flowers in july and auguſt, but rarely ripens ſeeds in England.

[a] Hort. kew.

[2. Stem

[2. Stem twining, ſhrubby, even. Leaves oppoſite, petioled, even, underneath paler veined tranſverſely. Panicles axillary, alternate, dichotomous, ſhorter than the leaves. Flowers ſmall. It differs at firſt ſight from the preceding in its ſmall copious flowers [a].

Said to be a native of Egypt—but its place of growth is uncertain. It was cultivated in 1775, by John Fothergill, M. D. It flowers in july [b].

3. Corolla greeniſh-yellow within; the ſegments linear, blunt, with an orange dot above. Leaves ſimply veined [c].

Native of the Canary iſlands, where it was found by Maſſon. Introduced in 1779 [d].

4. Stem fruteſcent, from three to five feet high, upright, branched, ſometimes ſcandent by the top. Leaves ſome oppoſite, others in bundles, evergreen, ſmooth, ſharp at both ends, but ſometimes blunt, quite entire. Petioles ſhort, with two oppoſite tubercles at the baſe. Panicle axillary, the length of the leaves. Segments of the calyx blunt, falling with the ripe fruit. Segments of the corolla more produced on one ſide, purple within, the edges pale yellow, with a whitiſh ſubtomentoſe dot towards the middle. Scalelers (of the nectary) purple, ſomewhat fringed; and between them five purple bowed filaments, from the ſinuſes of the corolline ſegments: beſides theſe, there are five villoſe pedicelled ſcales, which are two-celled and ſurround the germ: they are the ſtamens (or anthers) of Linneus. There are alſo five ſmall bodies (which perhaps may be the ſtamens) club-ſhaped at the baſe, faſtened underneath to the peſta of the ſtyles; the apex cloven, and mealy or containing pollen, lodged in the cells of the ſcales: probably theſe are the anthers. Germ very ſmall, bifid. Styles two, ſhort. Stigmas two, covered with a fleſhy five-cornered pelta, within which the little club-ſhaped bodies are lodged. Capſules (or follicles) lanceolate, acute, even, horizontal, ſeſſile, oppoſite at the baſe. Seeds oblong, compreſſed; crowned with a white briſtly down [e]. Though very like the preceding, yet it is ſufficiently diſtinct from it, by its narrower veinleſs leaves, and the emarginate ſegments of the corolla [f].

Found by Billardiere near Laodicea by the ſea, and in the iſland Lampedoſa; by Desfontaines on mount Atlas; alſo on mount Shibel Iſchel in the kingdom of Tunis.

5. Root filiform, fibrous. Stems and branches numerous, twining, round, ſmooth, running over buſhes of conſiderable ſize. Leaves oppoſite, ſpreading, ſhort-petioled, linear tapering to a fine point, rounded at the baſe, entire, ſmooth, from four to ſix inches long, and about three-eighths of an inch broad. Racemes lateral, long, few-flowered. Flowers large, beautiful white with a ſmall tinge of the roſe, and ſtriated with purple veins; inodorous. Nectary and ſtamens as in Aſclepias and Pergularia. Follicles oblong, inflated [g].

Willdenow adds, that there are but two or three flowers in a raceme, and that they are pedicelled; that the corolla is yellow with ferruginous ſtreaks; the nectary five-horned, the genitals yellow, and the follicles ſmooth. His deſcription of the colour of the flower is taken from a dried ſpecimen. He ſays farther, that it varies in the width of the leaves; that he has ſpecimens with oblong-lanceolate, linear-lanceolate and linear-ſubulate leaves, but the ſecond predominate.

Native of the Eaſt Indies, called Oudy-palla by the Telingas. It grows in hedges, and among buſhes, on the banks of water-courſes, pools, &c. caſts its leaves during the dry ſeaſon, and is in flower and foliage during the rainy ſeaſon. Cattle eat it, but the natives do not, nor do they apply it to any purpoſe whatever. Its elegant flowers render it deſerving of a place in the flower garden [h].

6. Stem ſhrubby, with diffuſed rod-like, even branches. Leaves entire, ſmooth, ſhort-petioled, oppoſite. Peduncles ſhort, many-flowered, ſcaly with little bracteæ, eſpecially at the ends of the branches. Flowers ſmall, ſmooth.

Native of the Eaſt Indies, at the foot of mountains. Koenig ſent it from Tranquebar. Thunberg ſays that the root is uſed as an emetic in the Eaſt Indies [i].

7. Stem twining, round. Leaves oppoſite, ſmooth, quite entire, on very ſhort petioles: from the axils of them ſimple ſpikes come out imbricated with ſharp ſcales [k].

According to Burman, the ſtem is aſh-coloured, rugged with many very ſmall tubercles. A pair of leaves from each joint, almoſt ſeſſile, bright green above, pale and aſh-coloured underneath, oblong, acute, entire, veined; at the axils of theſe there are many flowers ſitting cloſe.—Native of the iſland of Ceylon.

8. Native of New Zealand [l].]

9. This has many ſlender ſtalks, which twine about each other, and by a ſhrub or other ſupport will riſe near three feet high, putting out ſeveral ſmall ſide-branches: theſe are hairy, as are alſo the leaves; which are about three quarters of an inch long, and half an inch broad, ſtanding by pairs upon very ſhort foot-ſtalks. The flowers come out in ſmall bunches from the ſide of the ſtalks; they are ſmall, of a dull purple colour, and have a ſweet ſcent. It flowers in the ſummer, but does not produce ſeeds here.

[Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1726 [m].]

There is a variety of it with ſmooth leaves and ſtalks from the ſame country.

[10. Stem twining, even. Leaves oppoſite, petioled, ſmooth on both ſides. Stipules cordate, petioled. Flowers ſmooth in axillary few-flowered umbels (two to five.) Koenig ſent it from Tranquebar.

11. Stems ſhrubby, tomentoſe. Leaves ovate, ſomewhat hirſute on both ſides, entire. Flowers ſmall in oppoſite axillary umbels, ſmooth within. Calyx tomentoſe, with the ſegments ovate, obtuſe.—Native of the Eaſt Indies; found by Koenig [n].

12. This is a middle-ſized tree, with ſpreading branches. Leaves heart-ſhaped, oblong, acute, quite entire, large, ſmooth, oppoſite. Flowers blueiſh white, on ſhort racemes. Calyx five-leaved; leaflets lanceolate, ſpread out. Nectary ſurrounding the genitals with five filiform upright little columns, curved at the baſe.

Native of Cochinchina, to the ſouth of Huæa the metropolis. It occurs alſo in Bengal, but of a ſmaller ſize [o].]

13. This riſes with a ſtrong woody ſtalk to the height of five or ſix feet, covered with a gray bark, putting out many weak branches, which twiſt themſelves about any neighbouring ſupport, and riſe to the height of twenty feet; they are garniſhed with heart-ſhaped leaves three inches long, and two broad near their baſe; they are of a yellowiſh green, covered with ſilky hairs, which are ſoft to the touch; and ſtand oppoſite upon pretty long foot-ſtalks. The flowers come out in ſmall bunches from the wings of the leaves; they are ſmall, white, and of the open bell ſhape; theſe are ſucceeded by ſwelling taper pods, filled with ſeeds crowned with long feathery down.

Diſcovered by Dr. Houſtoun at Vera Cruz in America.

PROPAGATION AND CULTURE.

1. This is eaſily propagated by laying down the branches, which will put out roots in one year, and may then be cut from the old plant, and planted where they are to remain. Theſe may be tranſplanted either in autumn, when the leaves begin to fall, or in the ſpring before they begin to ſhoot, and muſt be planted where they may have ſupport, otherwiſe they will trail on the ground, and faſten themſelves about whatever plants are near them.

9. The ninth ſort is hardy enough to thrive in this country, with a little protection from the froſt in winter. If the plants are ſheltered under a common frame or placed in a green-houſe during the winter ſeaſon, and

placed

placed abroad with other hardy exotic plants in ſummer, they will thrive and flower very well; but as all the plants of this genus have a milky juice, ſo they ſhould not have much wet, eſpecially in cold weather, leſt it rot them. They are eaſily propagated by laying down their branches, which in one year will have roots enough to tranſplant; theſe ſhould be planted in a light ſandy loam not rich, and the pots muſt not be too large, for when they are over potted they will not thrive.

13. The thirteenth ſort being tender, will not thrive in England, unleſs the plants are placed in a warm ſtove. They may be propagated by laying down their branches in the ſame manner as the former; or from ſeeds, when they can be procured from the places where they naturally grow. Theſe ſhould be ſown upon a good hot-bed, and when the plants come up, they muſt be treated in the ſame manner as other tender exotic plants.

If theſe plants are conſtantly kept plunged in the tan-bed of the ſtove, they will thrive and flower much better than in any other ſituation, but the ſtove ſhould not be kept too warm in winter; and in the ſummer the plants ſhould have a large ſhare of free air admitted to them; for when they are kept too cloſe, their leaves will be covered with inſects, and the plants will become ſickly in a ſhort time.

DESCRIPTIONS, &c.

1. Culm a foot and half high, frequently jointed to a third part of its height, the joints half an inch and an inch diſtant from each other; from each joint ſprings a branch, which is alſo frequently jointed, and terminated by a ſpike. Leaf at each joint waved and as it were curled, an inch long or leſs, a line and half or two lines wide, ſmooth, with a white line, and ſhort looſe ſtiffiſh hairs at the edge. Sheath half an inch or an inch in length, whitiſh eſpecially towards its origin; ending in a ſcarcely viſible whitiſh ligule. Spike a hand or half a foot in length, very thin. Florets pedicelled, a line long, livid or purpliſh; awn very ſlender, yellowiſh or purple, four or five lines in length. Seed very ſlender, acuminate, brown, near a line long[1]. Petiver ſent it to Scheuchzer from London.—It is an annual graſs, native of the Eaſt Indies. Introduced in 1777 by Daniel Charles Solander, L. L. D. It flowers in auguſt and ſeptember[2].

The variety, according to Willdenow, is a diſtinct ſpecies of this genus.

2. Culm branched. Leaves linear, not waved. Sheaths bearded at the edge.—Native of the Eaſt Indies[3].

1. Petaloma myrtilloides.

Swartz prodr. 73. *Sloan. jam.* 2. 78. *t.* 187. *f.* 3.

Peduncles ſolitary one-flowered, leaves ſubſeſſile ovate attenuated obliquе at the baſe.

2. Petaloma Mouriri.

Lin. ſyſt. Gmel. 678. *Swartz prodr.* 73.

Mouriri guianenſis. *Aubl. guian.* 453. *t.* 180.

Peduncles corymbed axillary, leaves petioled ovate acuminate, berries four-ſeeded.

DESCRIPTIONS, *&c.*

1. Trunk ſtraight, twenty feet high, no thicker than the human leg; bark almoſt ſmooth, gray, with ſome very white ſpots, whence its name of *Silver-wood.* Leaves in pairs, ſmooth, very thin, yelloviſh green, an inch long, and almoſt as broad at the baſe, entire. Flowers axillary, ſmall, white, on crooked pedicels. The wood is hard, tough, heavy, and good for looms, handles, ſtaves for oars, or ſcouring rods for guns.

Native of Jamaica, and other parts of the Weſt Indies [a].

2. This is a tree from thirty to forty feet in height, and a foot and half in diameter; with a grayiſh bark, and a whitiſh hard compact wood; with a great number of branches at top, ſome ſtraight, others inclined, ſpreading out in every direction, and ſubdividing into knobbed branchlets. Leaves at each knot in pairs ovate-acuminate, ſmooth, entire, ſtrong, thick, on ſhort petioles. Flowers axillary on oppoſite corymbs. A very ſmall bractle at the baſe of the common peduncle and pedicels, and two under the calyx. Corolla yellow.

Native of Guiana, in the foreſts bordering on the river Sinemari; flowering in november, and fruiting in january. Named by the natives *Mouriricbira* [b].]

[a] Sloane. [b] Aublet.

Lin. ſpec. Willd. 614. *Jacqu. amer.* 14. *t.* 182. *f.* 6.

[a] Linn. ſpec. [b] Forſter. [c] Jacquin.

DESCRIPTION, &c.

This is a small tree, with four-cornered striated branches. Leaves ovate-oblong, acuminate, quite entire, opposite. Flowers panicled, axillary.—Found in the island of St. Domingo, in woods, by Jacquin [1].]

PETIVERIA. *(So named by Plumier in honour of James Petiver, apothecary of London, author of* Museum, 1695, Gazophylacium, 1702, *collected into one volume folio, with many plates.)*

Lin. gen. n. 459. *Reich. n.* 494. *Schreb. n.* 623. & *p.* 828. *Plum.* 39. *Gærtn. t.* 75. *Juss.* 84.

Class. 6. 4. Hexandria Tetragynia. — Heptandria Monogynia. *Swartz.*

Nat. order of *Holoraceæ. Atriplices*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved: *leaflets* linear, blunt, equal, spreading, permanent.

COR. none (except the coloured calyx.)

STAM. *Filaments* six or eight, unequal, awl-shaped, converging. *Anthers* erect, linear-sagittate, bifid at top.

PIST. *Germ* ovate compressed, emarginate. *Style* very short, lateral, in the groove of the germ. (Styles four, permanent, finally bent outwards, spinescent, *G.*) *Stigma* pencil-shaped.

PER. none, except the crust over the seed.

SEED single, oblong, narrower below, roundish, compressed, emarginate: with four barbed hooks, bent back outwards, rigid, acute, the middle ones longer: (naked, but armed above with reflex spines. *G.*)

OBS. *The flowers have mostly seven stamens.* Sw.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* none. *Seed* one, with reflex awns at top.

SPECIES.

1. Petiveria alliacea. *Common Guinea-hen weed.*

Flowers eight-stamened.

DESCRIPTION, &c.

1. Root strong, striking deep into the ground. Stems from two to three feet high, jointed and becoming woody at bottom. Leaves oblong, three inches long and an inch and half broad, of a deep green and veined, placed alternately on short foot-stalks. The flowers are produced in slender spikes at the ends of the branches; they are very small and make no figure.

[Seed cuneiform-oblong, round-flatted, with an obscure ridge on one side and a depressed line on the other, armed at top with four pungent spines, at first almost upright, but afterwards reflected to the back; of a bay or pale-green colour [2].]

It is a common plant in most of the islands in the West Indies, where it grows in shady woods, and all the savannas, in such plenty as to become a troublesome weed. As this plant will endure much drought, it remains green when others are burned up: the cattle then feed on it, and it gives their milk the taste of Garlick, and an intolerable rankness to their flesh. It flowers here in june.

[Browne informs us that it is very common in all the lower lands of Jamaica, and that it is so remarkably acrid, as to render the smell and taste hardly tolerable. On chewing a little of the plant, it burns in the mouth, and leaves the tongue black, dry and rough, as it appears in a malignant fever. It is however thought to be coveted by Guinea Hens, and hence its name of *Guinea-hen weed.* It thrives most in a dry gravelly soil and a shady situation. Cultivated in 1758, by Mr. Miller [2].]

2. This is very like the first, but differs in having a shorter and narrower stalk, and in the flowers having eight stamens; but except to a nice observer, they may both pass for the same species. [Linnæus adds, that the leaves are more rigid and quite smooth, the filaments purple and not white. It is a mere variety of the preceding, according to Swartz.

Jacquin describes it as a shrubby plant, smelling strong of Garlick, differing from the common sort only in having eight filaments, which are all unequal, and the pencil-shaped body placed on the germ red, where as in the other it is white.

Native of the West Indies: according to Jacquin frequent in Martinico and the other Caribbee islands, flowering almost all the year.—It was cultivated in 1739, by Mr. Miller [3].]

PROPAGATION AND CULTURE.

These plants may be increased by slips or cuttings, as well as seeds; which must be sown on a hot-bed early in the spring. When the plants are come up, transplant each into a separate pot, and plunge the pots into a moderate hot-bed. When the plants have obtained a good share of strength, inure them by degrees to the open air, into which remove them towards the end of june, placing them in a warm situation, where they may remain till autumn, when they should be placed in the stove, and during winter have a moderate degree of warmth. They will produce flowers and seeds every summer, and will continue several years, remaining constantly green throughout the year.

[PETOLA. See *Momordica.*]

PETREA. *(So named by Houstoun, who discovered the plant at Vera Cruz in New Spain in* 1731, *in honour of Lord Petre, who possessed a noble collection of exotic plants, and was a great encourager of botany.)*

Lin. gen. n. 764. *Reich. n.* 822. *Schreb. n.* 1024. *Houst. reliq.* 11. *Jacqu. amer.* 180. *Juss.* 108.

Class. 14. 2. Didynamia Angiospermia.

Nat. order of *Personatæ. Vitices*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-shaped: *border* five-parted, spreading, very large, coloured, permanent: *segments* oblong, blunt, closed at the throat by five doubled, truncated scales.

COR. one-petalled, wheel-shaped, unequal, less than the calyx: *tube* very short: *border* flat, five-cleft: *segments* rounded, almost equal, spreading very much; the middle one larger and of a different colour.

STAM. *Filaments* four, concealed within the tube of the corolla, ascending, two shorter. *Anthers* oval, erect.

PIST. *Germ* ovate. *Style* simple, the length of the stamens. *Stigma* blunt.

PER. *Capsule* obovate, flat at top, two-celled, concealed at the bottom of the calyx.

SEED single, fleshy.

ESSENTIAL CHARACTER.

Cal. five-parted, very large, coloured. *Cor.* wheel-shaped. *Capf.* two-celled, at the bottom of the calyx. *Seeds* solitary.

SPECIES.

Petrea volubilis.

Lin. spec. 873. *Syst.* 565. *Reich.* 3. 163. *hort. cliff.* 319. *Jacqu. amer.* 180. *t.* 114. *pict.* 89. *t.* 173.

DESCRIPTION, &c.

It rises with a woody stalk to the height of fifteen or sixteen feet, covered with a light-gray bark, and sending out several long branches, having a whiter bark than the stem. Leaves at each joint, on the lower part of the branches placed by threes, but higher up by pairs; they are five inches long, and two inches and a half broad in the middle, drawing to a point at each end; they are stiff, and their surface is rough, of a light green, having a strong dark midrib, with several transverse veins running to the borders, which are entire. The flowers are produced at the ends of the branches in loose bunches, nine or ten inches long; each flower upon a slender pedicel about an inch in length. Calyx composed of five narrow obtuse segments, an inch long, of a fine blue colour, and much more conspicuous than the petals, which are white, and not more than half their length.

[1] Willdenow. [2] Gærtner. [3] Hort. kew. [4] Hort. kew.

Dr. Houſtoun found a variety of this with blue petals, of the ſame bright colour with the calyx, and making a fine appearance, each branch being terminated by a long ſtring of theſe flowers; whence he has ranked it among the firſt claſs of beautiful American trees.

[Jacquin deſcribes it as a ſhrubby plant, with rugged, round, brachiate branches, climbing trees to the height of twenty feet. Leaves ovate, acute, quite entire, very rugged on both ſides, petioled, oppoſite, three or four inches long. Racemes ſimple, looſe, the flowers pointing one way, handſome, terminating, pendulous, nine inches long, containing about thirty flowers; which are inodorous, open ſucceſſively, on long peduncles: calyx blue or blueiſh purple, corolla deep violet and caducous. The ſeeds very ſeldom ripen, the calyxes falling prematurely.

Native of South America and the Weſt Indian iſlands.

Linneus does honour to the nobleman from whom this plant was named, in the following words:—— "Periit egregius Petreus 1742, ætatis 32, variolis "correptus, longiori vita digniſſimus, utpote qui floræ "indicæ domicilia extruxit in Europa omnium ſplen-"didiſſima."]

PROPAGATION AND CULTURE.

This is propagated by ſeeds, which muſt be obtained from the places where the trees grow naturally, and very few of them are good; for, from the ſeeds which Dr. Houſtoun ſent to England, there were but two plants raiſed, though the ſeeds were diſtributed to ſeveral perſons; and this is a ſort of confirmation of the ſpikes of flowers being of different ſexes, and that the ſeeds gathered by the Doctor, were taken either from trees at ſome diſtance from the male, or ſuch parts of the ſame tree which were remote from the male flowers. The ſeeds muſt be ſown in a good hot-bed, and when the plants come up, they ſhould be each planted in a ſeparate ſmall pot filled with light loamy earth, and plunged into a hot-bed of tanners bark, and afterwards placed in the bark-bed in the ſtove, where they ſhould conſtantly remain, and be treated like other plants of the ſame country.

[PETROCARYA. (*From πέτρος, a ſtone; and καρυον, a nut; the ſhell of which is as hard as a ſtone.*)

Leaves cordate.

DESCRIPTIONS, *&c.*

1. This is a very lofty tree, with a trunk eighty feet high, dividing at the top into very thick, wide-ſpreading branches; the ramulets or ſmaller branches being villoſe and reddiſh. The leaves are ovate and acuminate, perfectly entire and beſet on their under ſurface with a whitiſh down. The ſtipules are two, very broad, ſharp, oblong, and deciduous; and are ſemi-amplexicaul at the baſes of the leaves. The flowers are raceme-terminal; the common footſtalk being downy and whitiſh. The flowers are white. The drupe ſmooth and fulvous; it has a thick acid bark; and the nut or kernel in each loculament of the putamen is ſweet and edible. Sometimes one of the ſeeds is abortive.

A native of woods in Guiana.

2. A tree, with a trunk from thirty to forty feet high, branching at top: ramulets villoſe and whitiſh: leaves alternate, ſubſeſſile, green above, whitiſh beneath. Stipules as in the former. Flowers racemoſe, axillary, terminal, and reſembling thoſe of the former ſpecies. Drupe ovate, ſmall, with a thick, brown-green bark, which is alſo acid. Putamen very hard, compreſſed, wrinkled and unequal. A ſingle edible ſweet ſeed in each loculament.

In woods in Guiana.]

DESCRIPTION, *&c.*

1. Root perennial, dividing into many ſtrong fibres which run deep in the ground. Leaves naked at bottom, but about four or five inches from the root branching into five parts, and theſe again into three, each of theſe diviſions ſuſtaining three narrow leaflets, which, when bruiſed, emit a ſtrong ſcent like ſulphur: footſtalks channelled. Stems near two feet high, channelled, and dividing into two or three branches, each terminated by a large regular umbel of yellow flowers, compoſed of ſeveral ſmall umbels which are circular.

[Stem upright, from two to four feet high, ſlightly ſtriated, bright green, jointed, ſmooth. Leaves alternate, ſheathing: leaflets quite entire, mucronate, ſtiffiſh, flat, one, two or three inches in length, and a line in width, bright green, ſmooth. Umbel large, the outer rays longeſt [a]. Fruit middle-ſized, compreſſed into the ſhape of a thin lens. Seeds ſubfoliaceous, ſurrounded by a very narrow attenuated rim, having on the flat ſide two dark-ferruginous fillets, as in the Parſnep [b].

Native of the moſt ſouthern parts of Europe, in moiſt meadows. In England, Gerarde found it growing very plentifully on the ſouth ſide of a wood belonging to Waltham, at the Naſe in Eſſex, alſo at Whitſtable and Feverſham in Kent. Ray obſerved it near Shoreham in Suſſex; and adds, that it was ſaid to grow abundantly on the banks of the Thames, and in the marſh ditches near Walton, not far from Harwich. James Sherard, M. D. found it a quarter of a mile below Feverſham. Mr. Humphrey about Yarmouth and Clay in Norfolk. On the ſea wall leading to Thorne, near Feverſham, by Blackſtone. It flowers in june and july.

In England, ſays Gerarde, it is called *Horſeſtrange* and *Horſeſtreng* (or *Hareſtrang*, from the German *Haarſtrang*), *Sow-Fennell* or *Hog's-Fennell*, *Sulphur-wort* or *Brimſtone-wort*.

The root has a ſtrong fetid ſmell, and an acrid bitteriſh unctuous taſte. Wounded in the ſpring, it yields a conſiderable quantity of yellow juice, which dries into a gummy reſin, and retains the ſtrong ſcent of the root. Its virtues have not yet been aſcertained with preciſion [c].]

β. Italian Sulphur-wort is a larger plant; the leaflets are much longer, and the flowers and ſeeds are much larger. It grows on the mountains, and alſo in the low vallies, by the ſide of rivers, in Italy.

2. Root perennial. Leaves branching into ſeveral diviſions, that divide again into ſmaller, each of the latter having five ſhort narrow leaflets. Stems round, not ſo deeply channelled as in the preceding, ſuſtaining a large umbel of yellow flowers. The ſeeds are ſhorter. It flowers in june, and the ſeeds ripen at the beginning of ſeptember.

It is a native of the foreſt of Fontainbleau, and ſome other parts of France.

[3. 4. Natives of the Cape of Good Hope,

5. Leaves ſuperdecompound, with long leaflets running down into the partial petiole; the lower ſtem-leaves have a wide ſheath at the baſe. The primary umbel is ſeſſile in the diviſion of the ſtem; the reſt are peduncled. It has no univerſal involucre. The involucrets have many very ſhort briſtle-ſhaped leaflets. Petals bent in. Styles permanent, divaricating. Native of Siberia [d].

6. The whole plant is ſmooth. Stem round, flexuoſe, upright, branched, the thickneſs of a gooſe quill, ſcarcely a foot high. Branches alternate, divaricating, ſubdivided, reſembling the ſtem. Leaves petioled; leaflets five-cleft or three-cleft. Sheath of the petiole embracing, wide, ſtriated. Umbels many-rayed, ſubfaſtigiate. Seeds ovate, compreſſed, marked with raiſed lines, a little winged at the edge.—Native of Japan, on the coaſt [e].

7. Root perennial, long, wrinkled, black on the outſide, white within, having a ſweet aromatic flavour with ſome ſharpneſs. Stems ſeveral, from two to three feet in height, almoſt as thick as the little finger at bottom, round, ſtriated, full of pith, red near the ground, branched from the bottom, the branchlets coming out at long intervals from the axils of the leaves. Both root and ſtem-leaves ſmooth, dark green, divided into longiſh, narrow, acute, rigid ſegments. Umbels not very large or cloſe, but rather looſe and thin [f]. The involucre has only one or two leaflets: the involucel has twelve lanceolate leaflets, deep purple or black at the ends. The umbel has only ſeven rays, but the umbellules from twelve to twenty and upwards. The flowers are generally all fertile, but ſome of the central ones are ſometimes barren. Petals whitiſh yellow, pointed, (entire, equal.) Germ crowned with a glandular yellow receptacle, turning to a deep red as the ſeeds ripen [g]. Seeds ſhort, ſtriated, cheſtnut-coloured. The whole plant has a ſtrong, but not unpleaſant ſmell, approaching to that of Parſneps.

Native of many parts of Europe, as Switzerland,

[a] Pollich. [b] Gærtner. [c] Withering. [d] Willdenow. [e] Thunberg. [f] Ray. [g] Withering.

France,

France, Germany, England, &c. in moiſt meadows. It has the names *Saxifrage* and *Meadow Saxifraga* from its ſuppoſed ſtithontriptic qualities [k]. Auguſt is its month of flowering.

8. Stem upright, three or four feet in height, and ſometimes as high as a man, round, ſlightly ſtriated, grooved only towards the top, very ſmooth, tinged with red, and wholly red at the baſe, jointed, dichotomous. Leaves alternate, ſheathing; the lower ones tripinnate, the upper ones bipinnate; the laſt pinnas broadiſh, not ſimple, but two, three or four-lobed, bluntiſh, and terminating in a ſpinule, not keeled but flat; all of them are ſmooth and bright green. Umbel middle-ſized. Univerſal involucre of about eight leaflets: partial many-leaved. Petals regular, entire, ſmall, pale yellow. Seeds ovate, obtuſe, ſmooth, margined, with four or five longitudinal furrows in the middle [l].

Root perennial, forked, branched, black. Lower leaves decuſſating, ſmaller: pinnas veined and nerved, the firſt bifid, trifid or ſometimes ſimple, the laſt broadiſh, trifid. Univerſal involucre five or ſix-leaved: partial as many or more. Umbel of twenty or thirty unequal rays: umbellule of fewer and ſhorter. Petals ſulphur-coloured, ovate, reflex at the tip. Seeds at firſt violet red, then black [k].

Native of Germany, Auſtria, Alſace, Switzerland, Sileſia, Piedmont. Introduced in 1774, by Monſ. Richard. It flowers in june and july.

9. Native of the Canary iſlands, where it was found by Maſſon; and introduced in 1779. It is a biennial plant, and flowers in june [l].]

10. The ſtalks riſe a foot and half high, having pretty large knots at the joints, from each of which ſprings a leaf cut into many diviſions; the flowers terminate the ſtalks in umbels, and appear the beginning of july; in warm ſeaſons the ſeeds will ripen in the autumn.

Native of Crete or Candia, and not of long duration in England. [Cultivated by Mr. Miller in 1768.

11. Native of New Zealand [m].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds ſown in the autumn, ſoon after they are ripe: thoſe which are ſown in the ſpring ſeldom ſucceeding, or at beſt not coming up till the ſpring following. Keep the plants clean from weeds, and in the autumn tranſplant them where they are to remain. They love a moiſt ſoil and a ſhady ſituation, but will not thrive under the drip of trees.

PEVETTI. See *Phyſalis.*

PEZIZA.

Claſſ. 24. 6. Cryptogamia Fungi.

GENERIC CHARACTER.

Fungus bell-ſhaped, ſeſſile, concealing lens-ſhaped, ſeed-bearing bodies.—Plant concave; ſeeds on the upper ſurface only: diſcharged by jerks. *Withering.*

Of this genus of *Fungus*, Linneus has eleven ſpecies in the 14th edition of *Syſtema Vegetabilium*: but Dr. Withering has given no leſs than forty Britiſh ſpecies, in the third edition of his Arrangement.

PEZIZA. See *Nidularia* and *Oſtoſpora.*]

PHACA. (Φακὸς *of Dioſcorides.*)

Lin. gen. n. 891. *Reich. n.* 964. *Schreb. n.* 1207, *Gærtn. t.* 154. *Juſſ.* 358. Aſtragaloides. *Tournef. t.* 223.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ.*

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, five-toothed.

COR. papilionaceous. *Standard* obovate, ſtraight, larger. *Wings* oblong, blunt, ſhorter. *Keel* ſhort, compreſſed, blunt.

STAM. *Filaments* diadelphous (ſimple and nine-cleft.) *Authers* roundiſh, aſcending.

PIST. *Germ* oblong. *Style* awl-ſhaped, aſcending. *Stigma* ſimple.

PER. *Legume* oblong, inflated, half two-celled; with the upper future depreſſed towards the lower.

SEEDS ſeveral, kidney-form.

OBS. *Legume in ſome ſtraight, in others recurved, ſo that the lip almoſt touches the baſe.*

In ſome ſpecies of Aſtragalus, the partition of the Legume not being faſtened to the lower future, though it approximates to it, the great affinity between that genus and this is apparent.

ESSENTIAL CHARACTER.

Legume half-two-celled.

[k] Ray. [l] Pollich. [m] Krocker. Forſter. [f] Hort. kew.

DESCRIPTIONS, *&c.*

1. Roots perennial, running very deep into the ground. Stems commonly near four feet high, becoming woody, but decaying every autumn. Flowers in ſhort axillary ſpikes, ſeldom opening in England, unleſs the ſeaſon proves very warm, and never producing ſeeds here.

Native of Spain and Portugal. [Cultivated here in 1640, as appears from Parkinſon [a].]

2. This has ſmooth ſtalks, which do not riſe ſo high as thoſe of the preceding; the flowers are ſmaller, the pods ſhorter and hanging down. It flowers in two years from ſeed, and the roots rarely live longer than three or four years.

[Plant a foot high. Stem angular, ſtriated, almoſt upright, but bending from leaf to leaf. Leaves pinnate, alternate, longer than the internodes: leaflets ovate-oblong, blunt, from ſeven to fifteen, ſmooth, pubeſcent underneath. Stipules haſtate, acute, quite entire. Peduncles thicker and longer than the petioles, angular, naked, upright. Raceme looſe; pedicels the length of the calyxes; bractes lanceolate, commonly longer than the pedicel. Flowers pendulous, imbricate, ſmooth, yellow. Calyx bell-ſhaped, ſmooth, with brown teeth. Corolla oblong, yellow. Germ pedicelled, hairy. Legume ſemiovate, compreſſed [b].

Stems firm, ſtraight, villoſe, branched, two feet high, with membranaceous, lanceolate, cordate or triangular ſtipules, ſeven or eight lines in length; thoſe at the baſe of the leaves are narrower, but often as long as the leaflets; which are villoſe, oblong, in twelve or fourteen pairs. Peduncles from the axils of the upper leaves, villoſe, terminating in a ſpike of flowers of a fine yellow colour: wings quite entire; keel without any ſpot. Calyx ſmall, villoſe and blackiſh. Legumes villoſe when young, but becoming ſmooth before they have attained their full ſize, inflated, pointed on both ſides and irregular, the upper future being ſtraight, the lower very convex. Seeds eight [c].

According to Villars, Linneus has confounded *Phaca frigida* of Jacquin, with *P. alpina*; or perhaps he was not acquainted with the *Ph. alpina* of Dauphiné. Haller, in his later works has diſtinguiſhed them.

Jacquin thus deſcribes it. Root perennial, reſembling that of *P. auſtralis*; producing ſeveral ſtems, about a ſpan long, upright, but ſometimes procumbent at the baſe, round, ſtriated, at firſt villoſe, but becoming almoſt ſmooth. Leaves having from twelve to fifteen pairs of pinnas with an odd one: the pinnules on very ſhort petioles, oblong-oval, quite entire, having a ſhort little cuſp at the tip, ſmooth above, villoſe underneath: the common axis of the pinnas alſo villoſe. Stipules ſeſſile, entire, lanceolate, villoſe. Common peduncles from almoſt all the axils, erect, villoſe, longer than the leaves, having at top a compact ſpike of flowers, which is afterwards drawn out into length, with the flowers ſomewhat remote from each other. Flowers erect, on very ſhort pedicels, from the axil of a very ſmall, linear-ſubulate bracte. Calyx beſet with blackiſh, villoſe hairs. Corolla yellow, of one colour: ſtandard longer than the wings and keel, obcordate, the ſides a little plaited back; wings converging about the keel, on a longiſh claw, having a lateral toothlet; keel of the ſame length with the wings, having a ſimilar toothlet on each ſide. Germ pedicelled, linear, compreſſed, reddiſh black. Legumes at firſt nodding, finally pendulous, boat-ſhaped; the belly inflated, the back ſo much impreſſed, that the legume is half-two-celled; they are villoſe even when ripe, though the hairs, being proſtrate, and leſs black, are leſs apparent. Seeds round. The plant has no ſmell [d].

Native of Siberia, Lapland, Auſtria, &c. Cultivated by Mr. Miller in 1759. It flowers in july [e].

Jacquin doubts whether the *Phaca* which Gerard has deſcribed in his Flora Gallo-provincialis be the ſame with this; the leaves being ſomewhat different, and the habit very much ſo. See *n.* 5.

3. In the herb and form of the legumes this very much reſembles *Aſtragalus chinenſis*. Native of Siberia [f].

4. The whole is cloathed with ſoft white hairs. Leaves pinnate to the very inſertion, ſilky. Peduncles ſhorter than the leaves. Corollas purple. Legumes ovate, woolly.

Native of Siberia, in very dry ſand. Both theſe were found by Profeſſor Pallas [g].

5. Leaves ſix-paired or thereabouts, aſh-coloured, hairy. Flowers whitiſh yellow. Wings ſemibifid, which is ſingular. Legumes ſmooth. The keel of the corolla is violet, nor has it the two violet ſpots at the tip, as in *Ph. alpina*, from which it differs little. When young it is hirſute, but as it advances becomes ſmooth, and appears like a different plant [h].

Villars deſcribes it under the name of *Phaca Halleri*. Root hard, ſmall, creeping, divided at the upper part into ſeveral branches. Stems ſeveral, ſmooth, almoſt ſtraight, half a foot long, ſometimes branched. Leaves on a petiole naked at the baſe, placed between two lanceolate ſtipules, compoſed of five or ſeven, as far as thirteen leaflets, which are lanceolate, tender, green, diſtinct, ſmooth, or very ſlightly villoſe underneath. Peduncles from the upper axils, exceeding the plant in height, and terminated by ten or twelve flowers, which are whitiſh or grayiſh, with a ſmall blackiſh ſtripe, correſponding with the extremity of the keel: ſtandard ſtraight, almoſt round, emarginate; wings oblong, with a triangular notch, equal to the two lateral pieces; a ſingular character which Haller notices, but which is found in ſome ſpecies of the *Aſtragalus*. Legumes pendulous and peduncled, inflated and ſmooth, in a blackiſh calyx; they are ſlightly villoſe, and contain from eight to ten ſeeds.

Villars deſcribes another, under the name of *Phaca Gerardi*, ſuppoſing it may probably be the plant of Monſ. Gerard, but neither Haller's n. 403. nor Linneus's *P. auſtralis*.

Roots hard, ſmall and branching as in the preceding. Stem from eight or ten inches to a foot in length, proſtrate. Stipules villoſe and ciliate, in other reſpects like thoſe of the *P. Halleri*. Flowers commonly on two peduncles, longer than the leaves. Leaflets fifteen or twenty in number, whitiſh. Calyx villoſe and blackiſh. Standard oblong, and ſtanding up: wings oblong, narrow, rounded at the end: keel a little ſhorter than the wings, having a little black at the end. Legume a little villoſe. It is difficult to diſtinguiſh theſe two plants, without ſeeing the wings of the corolla, which in the latter have not the ſingular character noticed by Haller and Linneus. *Ph. Gerardi* however ſeems to be more villoſe, and is leſs uncommon; the ſtems alſo are leſs proſtrate.

Native of the South of Europe. Introduced in 1779, by Anthony Chamier, Eſq. It flowers in may and june [i].

6. Stems filiform, branched. Leaves petioled. Leaflets tomentoſe underneath, marked with lines; the middle one larger. Stipules lanceolate, drying up, having a briſtle-ſhaped point. Raceme terminating: pedicels geminate, one-flowered. Legumes blunt, the upper future running out into a briſtle-ſhaped recurved dagger-point.—Native of China [k].

7. Root-leaves pinnate, twelve-paired and more. Leaflets ſmooth, acuminate. Scapes upright, terminated by a raceme. Calyxes alternate, on ſhort peduncles, when fruiting four times wider, globular, ſmooth, coloured. Legume ſmall, within the oblong calyx.—Native of the Levant [l], where it was found by Tournefort.

8. Leaves pinnate: leaflets thirty-nine to forty five, ſeſſile: the lower oppoſite; the upper ones gradually ſmaller, alternate. Stipules lanceolate, hirſute, imbricate, at the baſe of the leaves. Scape a ſpan long, round, upright. Flowers ſeſſile: the lower ones more remote, ſpreading. Bracte ovate, villoſe, acute. Flowering calyxes cylindrical, ſoftly villoſe, brown; the younger ones ſubtomentoſe: teeth five, awl ſhaped, ſmall. Corolla a little longer than the calyx. It differs from the preceding in its hoarineſs, the villoſeneſs of the fruiting calyxes, and in having oblong, blunt,

[a] Hort. kew. [b] Linn. ſuec. [c] Villars. [d] Miſc. 2. 93. [e] Hort. kew. [f] Linn. ſuppl. [g] Linn. ſuppl. [h] Linn. mant. & ſyſt. [i] Hort. kew. [k] Linn. mant. [l] Idem.

approximating leaflets.—Native of Armenia[a], where it was found by Tournefort.

9. A radical tuft, compoſed of very villoſe white ſcales. Leaves fewer, on longer ſomewhat ſpiral petioles. Scapes radical, looſe, almoſt ſmooth, ſcarcely larger than the leaves.—Found by Profeſſor Pallas in the ſalt ſands about the lakes of Siberia.

10. Leaves fewer, ſhorter, on very villoſe petioles: leaflets very ſmall. Scapes pubeſcent, erect. Calyxes ſmooth, but tubercled: teeth with black hairs. Corolla large, purple.—Found by Pallas in the ſandy iſlands of Siberia.

11. Root-leaves ſeveral, from a villoſe tuft, longer. Leaflets as it were in whorls, channelled, ſmooth within, tubercled underneath. Scapes erect, ſmooth. Braſtes and calyxes ſmooth. Corollas yellow. Legumes long, bowed, muricate.—Found by Pallas in the mountainous fields of Siberia.

The third, fourth, ninth, tenth and eleventh ſpecies have the habit of *Aſtragalus*. Perhaps *Aſtragalus verticillaris*, and many *Phacæ* deſcribed and figured by Pallas belong to this genus[b].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, ſown in the place where the plants are to remain: for as the roots ſtrike deep, it is difficult to tranſplant them ſafely, eſpecially when they have remained long in the ſeed-bed. The plants ſhould be left about ſix feet aſunder, that there may be room to dig between them every ſpring, which is all the culture they require, except keeping them clean from weeds.

[PHACA. See *Aſtragalus*.

PHAETHUSA. (*From* Φαεθω, *ſplendeo.*)

Lin. gen. Schreb. n. 1319. *Gærtn. t.* 169.

Claſſ. 19. 2. Syngeneſia Polygamia Superflua.

GENERIC CHARACTER.

CAL. *Common* many-leaved: *leaflets* in a double row, oblong, gaping at the tip, blunt.

COR. *Compound*, half-radiate. *Corollets* hermaphrodite ſeveral in the diſk: *females* one to three in the ray, only on one ſide of the flower.

Proper of the hermaphrodites funnel-form, five-toothed, pubeſcent.

Female liguiate, oblong, toothed, very long.

STAM. in the hermaphrodites: *Filaments* five, very ſhort. *Anther* cylindrical, tubular, a little longer than the corolla.

PIST. in the hermaprodites: *Germ* oblong, villoſe. *Style* filiform, longer than the ſtamens. *Stigmas* two, reflex.

In the *females*: *Germ* oblong, a little bigger. *Style* filiform, the length of the hermaphrodites. *Stigmas* two, reflex.

PER. none. *Calyx* unchanged.

SEEDS in the hermaphrodites ſolitary, oblong, compreſſed, villoſe. *Down* of two awns. In the *females* very like the others.

REC. chaffy: *chaffs* linear, acute, longer than the calyx.

ESSENTIAL CHARACTER.

Cal. ſubcylindric, many-leaved, with unequal recurved ſcales. *Florets* hermaphrodite ſeveral in the diſk: females one or two in the ray. *Recept.* chaffy. *Seeds* hiſpid, without any proper down.

DESCRIPTION, *&c.*

Stem gigantic, eighteen feet high, narrowly four-winged by the decurrent petioles. Leaves large, oppoſite, ovate-acuminate, triple-nerved, obſoletely ſerrate, ſubpubeſcent. Corymb terminating brachiate, very wide. Hermaphrodite corollets hirſute on the outſide, with prominent dark-coloured anthers. Females commonly ſolitary, ſcarcely ever in threes: ligule ſulphur-coloured, ovate, attenuated to both ends, very ſhortly two-toothed at the tip. Down none, except the ſhagginеſs of the ſeed produced a little above the top of it, reſembling a chaffy-lacerated rim. It differs abundantly both from *Sigeſtheckia* and *Milleria*, in the whole of its external habit, the florets and ſeeds; inſomuch that it cannot be aſſociated with either[c].—Native of Virginia.

Spikes digitate, glumes rugged, leaves ovate.

DESCRIPTIONS, *&c.*

1. Root annual. Culm from a foot to eighteen inches in height, upright, round, ſtriated, ſwelling a little at the joints, and at the lower ones often branching. Leaves almoſt half an inch in breadth, of a lively green, with ſomething of a glaucous hue; they grow upright, are ſharp-pointed, roughiſh about the edge, and have at the baſe a very thin pellucid membrane or ligule: the lower part of the upper leaf ſwells out like a ſpathe, completely involving and protecting the head of flowers whilſt young. This is ſingle, large, an inch or more in length, and has a ſmall linear ſheathleſs leaf at the baſe of it. Valves of the calyx much larger than thoſe of the corolla, with two green ribs on each ſide. Within theſe are two other ſmall white ſkinny valves, not more than half the length of the inner valves of the corolla, the larger valve of which is hairy, the other only ſo along its back. The nectary is two fleſhy concave pear-ſhaped ſubſtances on the outſide the baſe of the corolla[d]. Seed marked with a blackiſh-brown line at one edge, and having a little ſhield at the baſe of the other; it continues covered with the corolla, one valve of which almoſt wholly embraces the other. This cover varies much in colour, being milk-white, ſtraw-coloured, aſh-coloured, livid, bay, cheſtnut and even black, but it is always very ſmooth and ſhining[e].

Canary-graſs is a native of the Canary iſlands, but is now found in a wild ſtate in Britain, Flanders, Heſſe, Sileſia, France, Italy and Spain. Our circumnavigators alſo diſcovered it in New Zealand. It is not mentioned as an indigenous plant with us by any of our old authors, not even in the third edition of Ray's ſynopſis (1724). It does not ſeem to be found in our iſland, except about dunghills, or by road ſides, in places where it may have been thrown out among rubbiſh, or caſually dropped by birds. Dr. Withering mentions that it has been found by Mr. Ballard in New's-wood, adjoining to Malvern, Worceſterſhire. Dr. Sibthorp obſerved it behind the Obſervatory at Oxford: and Dr. Milne near New Croſs, on the Maidſtone road, by Deptford Creek, and in Charlton wood. It flowers from june to auguſt; and is cultivated for the ſake of the ſeeds, which are the beſt food for the Canary and other ſmall birds.

2. Root annual, according to Linneus; perennial and bulbous, according to Deſfontaines. Culm reedy. From the ſwelling ſheath of the upper leaf iſſues one ſmooth thick ſpike-ſhaped panicle of an oblong-ovate form. The glumes are lanceolate, ſmooth, keeled, and marked with a nerve on each ſide, pretty much like thoſe of the preceding.

Retzius deſcribes his *Ph. minor* as an annual graſs, reſembling *Ph. canarienſis*, but ſmaller, the panicle narrower and not ventricoſe. Between the leſſer ciliate glume of the corolla and the calyx there is a leaflet which may paſs for the nectary, although it is on the outſide of the corolla. The ſeeds were ſent him under the name of *Ph. tuberoſa*, but the root has no tubers.

Native of Egypt. Introduced in 1778 by Monſ. Thouin. It flowers in june and july[f].

3. This is an annual graſs, native of the Cape of Good Hope.

4. Culm a foot high, ſwelling out at the baſe, commonly into three round bulbs, one above another, the lower having filiform fibres at the bottom. Leaves for an inch and more having a ventricoſe ſheath, above which they grow upright, and are lanceolate and acute. Flowers in a cloſe, cylindrical ſpike-like panicle; each on a ſhort pedicel[g].

It differs from *Ph. canarienſis* in having a more ſlender ſpike, of a cylindric ſhape. The ſeeds are only half the ſize, of a gray colour, and do not adhere to the glume. The ſeeds are gathered by the Moors and ſent into Europe[h].

Native of Spain, the Levant and Barbary; in which latter country the roots are not bulbous[i]: but that in graſſes does not make a ſpecific diſtinction.

Deſfontaines has a graſs which he names *Phalaris cæruleſcens*, and to which he refers the ſynonym of Buxbaum (4. 30. *t.* 53. attributed by Linneus to *Ph. aquatica*. It has a looſer ſpike than *Ph. bulboſa*, and the glumes are blueiſh. The culm is upright, naked above, and filiform. The leaves ſmooth. The ſpike branched, round, looſiſh. The outer calyx two-glumed, one-flowered: glumes membranaceous, keeled, acuminate, converging, almoſt equal, pale blue. Inner calyx alſo two-glumed: glumes ſmall, acute, almoſt equal, ſhorter than thoſe of the outer.—It is found in the arable fields about Algiers.

5. Leaves rigid, like thoſe of Reed, rugged at the edge; the uppermoſt ſlightly ventricoſe. Spike com-

[d] Withering. [e] Gærtner. [f] Hort. kew. [g] Cavanilles. [h] Deſfontaines. [i] Idem.

pact, ovate-oblong, awnleſs. Calyxes ovate-oblong. Native of the South of Europe [k].

6. This has the ſtature of P. phleoides. Culms ſmooth, with ſhort leaves. Glumes compreſſed: keel cartilaginous, toothed: teeth globuliferous at the tip. It is a handſome graſs, and very diſtinct at firſt ſight [l]. In the Supplement the glumes are ſaid to be hirſute; but Retzius ſays, that in his ſpecimen they are ſmooth and naked.—Native of the Cape of Good Hope.

7. Root fibrous, perennial, crowned with tufts of ſpreading glaucous leaves which endure the whole winter. Culm ſimple, generally ſolitary, moſt leafy below, round, ſmooth, purple and ſhining above, from ten to eighteen inches in height. Leaves ſheathing, linear-lanceolate, rough at the edge, their ſheaths ſcarcely inflated, roughiſh. Panicle ſolitary, erect, denſe, exactly like a ſpike, but when bent on one ſide it ſeparates into lobes or branches of ſeveral flowers each. Calyx nearly linear, ſomewhat conſtricted near the top, purpliſh; valves compreſſed, pointed, three-nerved, a little divaricated at the point, and furniſhed with a white membranous margin, which at its ſummit is in ſome degree abrupt, approaching to the ſtructure of a *Phleum*: but it cannot be conſidered as ſuch, on account of its ſtrict affinity to *Phalaris arenaria*; from which it differs however in having a perennial root, a branched or panicled ſpike, glumes leſs frequently and completely ciliate, and lanceolate (not abrupt or crenate) petals [m]. Dr. Withering obſerves, that the panicle is from near two inches to three inches and a half in length, thick as a gooſe quill: and Dr. Stokes, that a ſtiff awn-like thread riſes from the baſe of the inner valve, one third of its length, analogous to that of *Arundo arenaria*. Linneus regards this graſs as intermediate between *Phalaris*, *Phleum* and *Alopecurus*.

Native of ſeveral parts of Europe and Siberia. In England firſt obſerved by Mr. Lyons in Cambridgeſhire, and afterwards by Mr. Hemſted on Chippenham park wall in the ſame county. Mr. Crowe and Mr. Woodward found it on Swaffham heath in Norfolk, in 1780. Theſe two gentlemen firſt determined it; Mr. Hudſon having ſuppoſed his *Phleum paniculatum*, to be Linneus's *Phalaris phleoides*, which laſt he probably never ſaw [n]. It flowers in june and july.

8. Root annual, fibrous, downy. Stems ſeveral, dividing from the crown of the root or a little higher as in Wheat, ſometimes bent at the joints, clothed with leaves, the edge of which is a little rough; their ſheaths long, inflated, ſtriated and ſmooth. The culm commonly very little exceeds the uppermoſt leaf, and is terminated by an upright rigid ſpike, ſwelling in the middle, conſiſting of a great number of erect thick-ſet flowers. Calyx green, with white keel-ribs and margin; valves lanceolate, gradually tapering to a ſharp point and by no means lopped or truncated as in *Phleum*; their keel, and ſometimes their margin is ciliated with white hairs. The corolla conſiſts of two ſhort crenated ſtriated petals. The ciliated valves diſtinguiſh this graſs from the preceding [o].

Native of ſeveral parts of Europe. In England common on ſandy coaſts and the neighbouring fields; as at Yarmouth, by Mr. Woodward; in Wales, on Newborough ſands, Angleſea, by Mr. Griffith; in Scotland, near Preſton Pans, by Mr. Dickſon; more inland, on Swaffham-heath, by James Crowe, Eſq. and on Newmarket-heath, by the Rev. Mr. Hemſted [p]. It flowers from june to auguſt.

9. Root annual, fibrous. Culms a ſpan high, upright, branched and ſheathing at the baſe. Leaves narrow, naked, ſhort. Panicle the thickneſs of a gooſe quill, from one to four inches in length. Calyx obcordate, pale green, hard; glumes equal, ventricoſe above, terminated by a dagger-point, ſlightly keeled. Glumes of the corolla equal. Seed oval, oblong, not at all compreſſed [q]. Sheaths of the leaves rough. Sheath-ſcale blunt. Panicle bending to one ſide. Calyx ſeſſile, imbricate, two-valved, one-flowered, pointed, bellying upwards. Corolla two-valved, awnleſs, ſhorter than the calyx [r].

Native of ſeveral parts of Europe, as France, Italy, Sicily. In England on Gogmagog-hills, Newmarket-heath, and near Bourn-bridge, in Cambridgeſhire; on the wall of Roſe-lane, Oxford, obſerved there by Dr. John Sibthorp; in the meadows below King's Weſton, near Briſtol.

10. Root annual, fibrous. Culms ſeveral, a foot high or more, round, ſmooth, upright, commonly ſimple, marked with paler lines viſible with a glaſs, more or leſs refracted at the joints, which are from one to three, and tinged with red. Leaves two lines wide, two or three inches long, ſmooth; with long, ſmooth ſheaths: the upper leaf has an inflated ſheath, from which the upper part of the culm iſſues. Spike an inch long or more: ſpikelets ſubſeſſile, oblong, compreſſed. Glumes awnleſs, equal, with a white membranaceous edge; the nerve and edges below ciliate; the back rounded and wider; thence contracted and verging to a ſharp point: a ſingle elliptic, ſmooth, awnleſs glume inveſts the germ. Awn ſlender, double the length of the glumes, not jointed, pale yellow, iſſuing from the receptacle, reddiſh at top. Seed roundiſh. The ſpikelets are not altogether ſeſſile. It is diſtinguiſhed from all the other ſpecies by having the ſheath of the upper leaf widened and ſwelling like a ſpathe.

Native of Italy; where it is annually ſown in meadows about Pavia and Milan for cattle. It flowers there in may, and is called *Mazzuchello* [s]. Dr. Smith found it as common in the gardens and waſte ground about Rome as *Poa annua* with us, flowering in april [t]. It was introduced in 1777, by Monſ. Thouin, and flowers here from june to auguſt [u].

11. Root annual, fibrous. Culms a foot high, ſeveral, upright, decumbent before flowering-time. Stem and leaves even, not pubeſcent. Spike oblong, cylindrical, diviſible like the reſt into racemelets or corymbs. Florets in each little corymb neuter ſeveral, and one fertile at the end. Calycine glumes compreſſed: valves membranaceous-keeled, mucronate. The lower half of the ſpike has the barren florets as it were præmorſe, whence it ſeems as if gnawed off by inſects [x].

Native of the Levant and Barbary. Forſkahl ſent home ſeeds of it in 1762. It was introduced here in 1771, by Monſ. Richard, and flowers in june and july [y].

12. Culms capillary, decumbent, erect at top, jointed, ſmooth, branched, a foot high. Leaves ſheathing, (ſheaths glandular-hairy;) ſubcordate-ovate, acute, glandular-ciliate at the edge, ſmooth, ſpreading, ſcarcely an inch in length. Spikes from three to ſix: rachis flexuoſe, ſmooth: florets ſeſſile, alternate, imbricate, twice as long as the interſtices of the rachis: calycine glume lanceolate, acute, convoluted, marked with lines, ciliate-hiſpid, one-flowered. The calycine glume ſeems to be one-valved.

Native of Japan [z]. Willdenow remarks, that it is ſcarcely of this genus.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds thin in drills made a foot aſunder; when the plants come up, thin them where they are too cloſe, ſo as to leave them at near two inches diſtance in the rows. Hoe the grounds three times in the intervals, to deſtroy the weeds. Three gallons of ſeed is ſufficient to ſow an acre; and if the ſeed be ſown by a hopper, the ſpring of which is properly ſet, to let it out at equal diſtances, this will be the beſt method of cultivating Canary-graſs.

The cultivation of this graſs is chiefly confined to the iſle of Thanet, where it is eſteemed a profitable crop; and may be ſo, where there is water-carriage to London, for there is the principal demand for it.

[As this ſeed is a ſlow grower, it is liable to be overrun with weeds, for which reaſon it ſhould be ſown after clover on a gentle clay; but on ſtrong ſoils

[z] Thunberg.

a fallow is the beſt tilth. It is in general a valuable crop; and the chaff produces better, and a greater quantity of horſe-meat than any other. The ſeed ſhould be ſown at the end of february or beginning of march, in furrows twenty to the rod, and ſix gallons of ſeed to the acre. The land muſt be dunged with fifty or ſixty cart-loads on an acre [a].

Pileus or cap wrinkled red, covered with a greeniſh matter, conical, cloſed at the end: ſtem yellow, tapering at the bottom.

DESCRIPTIONS, &c.

1. Stem hollow, naked, white, one or two inches high, from half an inch to an inch in diameter. Cap entirely united to the ſtem, from the ſize of a pigeon's to that of a ſwan's egg; with very large cells, angular like a honeycomb: the colour of the cap is pale yellow or buff when young, but becomes brown when old. There is a variety which is ſmall and black, found on the ſandy heaths of Norfolk [b]. Mr. Sowerby gathered plenty of the blackiſh Morels at Newington in Surrey, on an old garden ground among ſugar-baker's rubbiſh. The Morel is commonly found in woods, under hedges, and among buſhes, in a loamy ſoil, and ſprings up in april or may. It has an agreeable ſmell.—It is common in many parts of the continent: in Britain it has been obſerved at Moor-Barns, Trumpington, Triplow, &c. in Magdalen-College walks, Headington-Wick coppice, and Shotover plantations. Mr. Jacob Rayer found ſome buff-coloured ſpecimens on a bank in Kent. It has been obſerved at Stone, Swanſcomb, &c. in that county: at Boughton, Walcot, Weekly, &c. in Northamptonſhire: near Aſpley and Outhorp in Nottinghamſhire: in Scotland, at Blair in Athol, in the woods at Langholm in Eſkdale, and in Logton wood near Dalkeith, &c.

According to Mr. Sowerby, in his elaborate work on Engliſh Fungi, the Morel belongs much more properly to the genus *Helvella*, if we conſider its texture, duration and qualities. It is well known and much eſteemed as an ingredient in gravies and ragouts, both recent and dried; for this purpoſe it may be kept many months or even years.

We are informed by Gleditſch, that Morels are obſerved to grow in the woods of Germany in the greateſt plenty where charcoal has been made. Hence the people who collected them to ſell, made fires in the woods, with heath, broom, &c. to obtain a more plentiful crop. Much miſchief having been done by this practice, it was found neceſſary to forbid it by law [c].

2. Roots fibrous; fibres large, round, white, creeping a little under the ſurface, with white globules or tubercles growing to them here and there, which when full grown project above ground; and appear in the form of eggs, a little flattened at the baſe, ſmooth, the ſize of a tennis-ball, white, and heavy. On the burſting of this the ſtalk riſes up, and is about the thickneſs of the thumb, four inches and more in height, a little crooked, round, white, ſpongy, hollow, very light, and pointed at both ends. Cap ſomewhat conical, ſitting looſely on the ſtalk, at firſt ſmooth, ſolid, olive-coloured, ſlippery, ſoon becoming highly fetid, the cells being as yet filled with the matter containing the ſeed, which flowing out or being eaten by flies, the outer ſurface appears cellular, the inner a little wrinkled, the top as if cut off, very white, oblong and open [d].

Though this Fungus is ſo intolerably fetid, yet in its egg ſtate it has no offenſive ſmell: the odour reſides in the green matter which fills the cells of the cap, and is commonly very ſoon devoured by flies, particularly the large blue fleſh fly. It remains many days in the egg ſtate before it burſts through its wrapper; but this being done, the ſtem puſhes up with amazing rapidity, attaining the height of four or five inches in a few hours. This offenſive green matter contains the ſeeds, which may be ſeen by the aſſiſtance of a good microſcope. Such as have courage to ſmell this matter cloſely, will find it much leſs diſagreeable than at a diſtance; for it then ſeems to have a ſlight pungency like that of volatile ſalts. The wrapper is filled with a clear jelly, like the white of an egg, but ſtiffer; within this is found the green matter, and within that the young plant. When it ſhoots up, the wrapper and the clear jelly remain at the root [e].

The diſagreeable carrion-like ſmell of this Fungus has occaſioned it to be called *Stinkhorns* in ſome counties. It nouriſhes not only ſeveral ſpecies of flies, but alſo Snails and Slugs, who are extremely fond of the ſtem.

In auguſt, ſeptember and october the ſtinking Morel appears in woods and hedge-rows, in ſome places abundantly, in others rarely, near London it has been found (about Hackney,) in Coomb-wood, Norwood (and in the cloſes about Streatham), but more plentifully in a ſmall fir wood on Hampſtead heath [f]. Mr. Woodward found it frequent near Bungay in Suffolk, in ſandy ſituations: Dr. Sibthorp in Kingſton woods, Oxfordſhire: Morton at Thorp-Malſor in Northamptonſhire: the Rev. Charles Abbot at Silſoe and Market-ſtreet in Bedfordſhire: Ray at Middleton, in Mr. Willoughby's orchard, Nottinghamſhire: Sibbald in the woods at Blair in Athol; and in the ſands by the

[f] Withering.

sea side on both sides of the Forth, and at Carubber bank, in Scotland.

3. Volva the size of a nutmeg, of an oblong ovate shape, white, smooth, gelatinous within, the inner coat cut off at top. Stalk beyond the volva, an inch and half or two inches in length, the size of a large goose quill, round, filiform, terminating in a point at bottom, cellular, somewhat transparent, of a pale orange colour, hollow within, soon becoming flaccid. Head sitting on the stem, sessile, about half an inch in length, and of the same diameter with the stem, oblong, a little pointed, impervious and whitish at top, at first of a livid colour, and covered with a very thin shining membrane, under which is a small quantity of a greenish liquid, almost without scent; which being removed, the surface of the head appears of a red colour, and transversely wrinkled, but by no means cellular, as in the stinking Morel.

Mr. Ehret, the celebrated botanic painter, in company with Mr. More, first discovered this Fungus in woods and shady places near Shrewsbury. Mr. Hunter, gardener to the Earl of Mansfield, found it sparingly in Caen wood, and communicated it to Mr. Dickson. And Mr. Sowerby, with Mr. Curtis, discovered it in Lord Mansfield's small pine wood, on the 20th of September, 1781. The Rev. Charles Abbot also found it about Silsoe in Bedfordshire. It differs from the *impudicus*, in having no *pileus* properly speaking, but the part on the outside of which the seminal matter is lodged forms a head, which is only a continuation of the stalk, differing in its structure and colour: this head has a wrinkled, not a reticulated surface, within these wrinkles, which are not very deep, the seminal matter is contained, and covered by a very thin membrane. The structure of the head in this species by no means agrees with Linneus's generic character of *Phallus*[a].

PHARNACEUM (*of Pliny. From Pharnaces, son of Mithridates, King of Pontus.*)

Lin. gen. n. 379. *Reich. n.* 410. *Schreb. n.* 517. *Juss.* 30. *Gærtn. t.* 130.

Class. 5. 3. Pentandria Trigynia.

Nat. order of *Caryophylleï*.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* subovate, concave, spreading, equal, permanent, coloured within, having a thin edge.

COR. none; hence the edge of the calyx is thin, and the inside of it is coloured.

STAM. *Filaments* five, awl-shaped, the length of the calyx. *Anthers* bifid at the base.

PIST. *Germ* ovate, three-cornered. *Styles* three, filiform, the length of the stamens. *Stigmas* blunt.

PER. *Capsule* ovate, obsoletely three-cornered, covered, three-celled, three-valved.

SEEDS numerous, shining, orbicular, depressed, surrounded by a sharp rim.

OBS. *The parts of fructification differ in* P. Mollugo.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* none. *Capf.* three-celled, many-seeded.

Racemes two-parted terminating, leaves obcordate.

DESCRIPTIONS, &c.

1. This is an annual plant, differing from *Mollugo* in little else than the number of stamens. Capsule ovate, thin, obsoletely three-grooved, slightly pustuled by the projecting seeds: partitions in the middle of the valves. Seeds eight or ten in each cell, small, roundish, beaked, marked on the back with a single filiform streak, very smooth and shining, of a rufous-ferruginous colour; fastened by very short umbilical cords to the central angle of the cells[b].

Native of Russia and Spain. Introduced in 1771, by Mons. Richard. It flowers in June[c].

2. Plant larger than *Spergula arvensis*. Stem even, prostrate, jointed with knobbed knots, dichotomously-branched. Leaves several, blunt, even, in whorls. Umbels peduncled, terminating and lateral, solitary, irregular[a].

[a] Curtis.

[b] Gærtner. [c] Hort. kew. [a] Linn. suppl.

3. 4. 5. Theſe and the preceding are natives of the Cape of Good Hope.

6. Root annual. Stems herbaceous, procumbent, dichotomous, jointed, round, even. Leaves in whorls, four or five, unequal in ſize, ſubpetioled, ſomewhat fleſhy, elliptic-lanceolate, even, ſharpiſh, rugged at the edge, ſcarcely veinleſs. Peduncles at the whorls (not at the forkings of the ſtem,) four or five, the length of the leaf, one-flowered. Calycine leaflets oblong-ovate, ſnow-white above, greeniſh more or leſs underneath, permanent. Petals very minute, linear, very narrow, ſemibifid, with briſtle-ſhaped ſegments. Nectary or briſtle awl-ſhaped, white, ſpreading, alternate with the filaments, and ſhorter than them. Stamens white, generally ſhorter than the petals. Germ ovate. Styles recurved, white. Anthers geminate, linear.

The plant in its whole appearance very much reſembles *Illecebrum ſcoideum*. The fructification is much like that of *Mollugo verticillata*, but it is a little larger. The petals reſemble greatly thoſe of *Glinus lotoides*. Burman's figure belongs to this ſpecies rather than to *Mollugo ſtricta*.

Mollugo verticillata differs from this in having the leaves fleſhy and bluntiſh, not mucronate; the flowers the length of the leaves, and not ſhorter by half; the calyxes the ſize of *Aſine media*, and not of *Herniaria*; the ſtem green, not the colour of ivory. It is a native of the Eaſt Indies [1]: and of Cochinchina, according to Loureiro.

7. Root annual. Stems herbaceous, even, flexuoſe. Leaves very many, in whorls, acute, ſmooth, even. Flowers very minute, few in a whorl, peduncled, beſides the little leafy glomerate umbel. It has the appearance of a *Mollugo*.

8. This is a tender annual plant, with the leaves and ſtem ſmaller than in *Herniaria glabra*. Stems branched, dichotomous, filiform, jointed, ſmooth. Leaves oppoſite or ſeveral, petioled, many times ſhorter than the internodes. Peduncles lateral, capillary, the length of the leaves.

9. The ſtems of this are ſomewhat ſhrubby, and have the appearance of a Heath. Leaves acerоſe, awl-ſhaped, minute, even. Panicles terminating, conglomerate, ſmall. Flowers white, on the outſide green [m].

10. This is alſo a ſhrubby plant, with an upright proliferous ſtem. Branches whitiſh with tunicated ſtipules. Leaves ſcattered, even, ſolitary, ſpreading. Stipules leafy, ſolitary, membranaceous, white, finely jagged. Peduncles terminating. Umbel compound, proliferous. Flowers white, green on the outſide [n]. Introduced in 1782, by George Wynch, Eſq. [o]

11. This is a little ſhrub with white ſtems. Leaves oppoſite, ſpreading, with the oppoſitions remote.

12. This and the five ſpecies preceding are natives of the Cape of Good Hope.—The tenth is alſo a native of Cochinchina, according to Loureiro.—The twelfth ſpecies is an annual plant, and was introduced in 1783, by John Earl of Bute. It flowers in july [p].

13. Leaves narrow, ſubtomentoſe. Racèmes geminate, flexuoſe. Piſtil one. Capſule one-celled, three-valved.—Native of the Eaſt Indies [q].

14. Root fibrous. Stems herbaceous, a foot high, proſtrate, even, knobbed at the joints. Branches alternate. Leaves numerous, in whorls, ſmooth, quite entire, much ſhorter than the internodes. Racemes peduncled. Flowers white, the ſize of thoſe of *Spergula arvenſis*.—Native of the Cape of Good Hope [r].

PHARUS. (Φαρος, *pallium*.)

Lin. gen. n. 1063. *Reich. n.* 1160. *Schreb. n.* 1434. *Juſſ.* 33. *Brown. t.* 38. *f.* 3.

Claſſ. 21. 6. Monoecia Hexandria.

Nat. order of *Gramina*, *Graminеæ* or *Graſſes*.

GENERIC CHARACTER.

* *Male* flowers peduncled.

Cal. *Glume* two-valved, one-flowered: *valves* ovate, membranaceous, coloured; *outer* ſhort, ſharpiſh; *inner* twice as long, rounded at the tip.

Cor. *Glume* two-valved, longer: *valves* equal, oblong, membranaceous, coloured; *outer* ſharpiſh, keeled below the tip; *inner* emarginate.

Stam. *Filaments* ſix, very ſhort, upright. *Anthers* linear, cloven at both ends, the length of the corolla.

* *Females* larger, ſeſſile in the ſame panicle.

Cal. *Glume* two-valved, one-flowered: *valves* lanceolate, membranaceous, ſharpiſh, nerved, almoſt equal.

Cor. *Glume* two-valved, a little longer: *outer valve* ſubcylindric, rigid, cloſely pubeſcent: end three-ſided, ſharp; back keeled, bent back, and ſhaved at the baſe: *inner valve* linear, very narrow, membranaceous, with the margins folded together, the edge thickened on both ſides, pubeſcent, with the tip cloven; the ſame length with the outer.

Pist. *Germ* linear. *Style* ſimple. *Stigmas* three, capillary, pubeſcent, prominent from the outer corolline glume.

Per. none. The outer glume of the corolla inveſts the ſeed, now larger, muricated all round with ſoft adhering little hooks.

Seed oblong, grooved on one ſide, large.

Obs. *Schreber could not obſerve any nectary.*

ESSENTIAL CHARACTER.

Cal. Glume two-valved, one-flowered.

Male. *Cor.* glume two-valved.

Fem. *Cor.* glume one-valved, long, involving. *Seed* one.

   Panicle umbelled, calyxes apetalous awned naked.

DESCRIPTIONS, *&c.*

1. This Graſs has many filaments three or four inches long, with lateral fibrils, uniting in a roundiſh root. Root-leaves ſeveral incompaſſing the ſtalk and one another by their foot-ſtalks, which are ſtriated of a light brown colour, and about nine inches long. Leaves oblong-ovate, ſix inches long and two broad, acuminate, ſtriated, thin, hard and rough, with the midrib prominent at the back. Stalk about a foot and half high, having below two very ſhort joints, dividing at a foot from the ground into ſeveral branches, on which are naked flowers, half an inch in length, ſeſſile, alternate. Outer glume blackiſh, and within that a long rolled-up membrane [s]. The male flowers are ſmaller than the females, and ſtand on pretty long peduncles at the back of the others.

This Graſs is frequent in all the woody hills of Jamaica, and reckoned a hearty wholeſome food for all ſorts of cattle. They call it there Wild Oats [t].

2. Culms very leafy, two feet high. Leaves linear, narrow, rugged. Panicle ſhort, or rather a ſimple raceme. Calycine valves ovate, convolute, having two grooves on the back, awnleſs, ciliate at the edge. Corolla none.

3. Culm above the water ſcarcely two feet high, at the joints under water many pectinate fibres, upright, leafy. Leaves lanceolate, ſhort, widiſh, naked, rough above, without any ligule. Sheaths on the barren branches ſwelling. Peduncles racemed, unequal. Pedicels thickened. Male flowers ſeveral lanceolate: ſtamens ſix, with very ſhort filaments, and long linear yellow anthers, ſlightly bifid at top. Female flowers fewer, below: germ minute, ſtyles two, ſtigmas white. Calyx in both two-glumed; outer glume five-nerved, awned, ciliate on the back and at the edges; inner narrower, longer except the awn, one-nerved, hyaline, acuminate, not awned. Corolla none in either.

Theſe Graſſes are natives of the Eaſt Indies, and nearly allied to *Phalaris aryzoides* [u].

DESCRIPTIONS, *&c.*

1. This is an annual plant, as are moſt of the other ſpecies. Stem more or leſs twining, but in ſome of the cultivated dwarf varieties ſcarce at all ſo, quite ſimple or unbranched. Leaves ternate, acuminate, rounded at the baſe, rough, on long petioles. Flowers axillary, in twin racemes, or elſe on twin petioles. Corolla white, yellow, purple or red. The banner has a callus, but a ſmall one, and placed near the edge above the claw. There is a white nectariferous ſcale between the claw of the banner and the ſingle ſtamen, bent upwards, and growing to the filament: beſides this an obliquely bell-ſhaped, pellucid, ſtriated nectary ſurrounds the pedicel of the germ within the connate filament: the ſize of this differs in the ſeveral varieties. The ſize of the bractes is an uncertain character[a]. Legume oblong, ſwelling a little at the ſeeds, when ripe one-celled. Seeds ſeveral, ovate or oblong kidney ſhaped, ſmooth and ſhining: they vary exceedingly in ſhape and ſize, but particularly in colour, being white, black, blue, red and variouſly ſpotted[b].

The common Kidney-bean is a native of both Indies. It was commonly cultivated here in the time of Gerarde (1597); but he does not ſpeak of any dwarf varieties, only of ſuch as "grow to a very great length, being "ſown near to long poles faſtened hard by them, or "hard by arbors or banqueting places; otherwiſe "they lie flat on the ground."—Parkinſon, in 1629, ſays that the variety with white flowers and ſeeds was then moſt uſual in the gardens; and that "Kidney-"beans boiled in water and ſtewed with butter, were "eſteemed more ſavory meat to many men's palates, "than the common Garden Bean, and were a diſh "more oftentimes at rich men's tables than at the "poor."

Kidney-beans are or were alſo called *Sparage-beans*; of ſome *Faſelles* or *long Peaſon*, *French Beans*, *Garden Smilax*, and *Roman Beans*[c].

The varieties of the Kidney-bean are very numerous. Mr. Miller mentions only] the ſmall White Dwarf, the Black Dwarf or Negro, and the Liver-coloured Bean, for early crops. The Batterſea and Canterbury. The large Dutch, which grows very tall.

β. He regards the Scarlet-bean as a diſtinct ſpecies. Its twining ſtalks, if properly ſupported, will riſe to the height of twelve or fourteen feet, the leaves are ſmaller than thoſe of the common Garden-bean. The flowers grow in large ſpikes, are much bigger, and of a deep ſcarlet colour. The pods are large and rough; and the ſeeds are purple marked with black; ſometimes pure white.

[Johnſon informs us (1633), "that it was pro-"cured by Mr. Tradeſcant, and grew in his time in "our gardens; that it is a large plant, not differing "in manner of growth from the former Indian Kidney "Beans, but that his flowers are large, many and of "an elegant ſcarlet colour; whence it is vulgarly "termed by our floriſts, the Scarlet Bean[d]."

In Ray's time (1686) it was cultivated rather for the beauty and durability of the flowers than for the fruit; and ladies did not then diſdain to put the flowers in their noſegays and garlands[e]. Mr. Miller ſeems to have been the firſt who brought it into much repute as an eſculent Kidney-bean; and I well remember his ſpeaking much in praiſe of it more than fifty years ſince, and that he preferred it at his own table.] The beſt ſorts for the table, ſays he, are the Scarlet-bloſſom Bean, and a white Bean of the ſame ſize and ſhape, which is only a variety of it.

2. The lateral leaflets are twice as wide on the outer ſide as on the other. Flowers very ſmall, green, with the wings white and concave, afterwards turning yellow, and the keel ſpiral[f].

The ſtem twines to the height of ten feet or more, and is branched. The three leaflets are even, ſharp, and unequal. Peduncles many-flowered. Flowers yellow, with a ſpreading green banner, of the ſame colour with the calyx. Legume compreſſed, wide, curved a little, acuminate, ſmooth. Seeds orbiculate-reniform, ſhining, black ſtreaked with white, large[g].

Native of the Eaſt Indies. It is eaten in Cochinchina, but is more eſteemed for the beauty than flavour of the ſeeds.

Introduced in 1779, by Mr. William Roxburgh. It flowers here in june and july[h].

3. This very much reſembles the P. rufus, agreeing with it in the flower, except that the banner is leſs green. Stems, leaves, and racemes a little hairy. Legume very ſlightly villoſe, and agreeing in ſhape and ſize with that of P. inamoenus, but more turgid, on account of the greater thickneſs of the ſeeds, which are few, white, ſubreniform, and marked on each ſide above the hile with a ferruginous ſpeck. Leaflets ovate-acuminate; the interior lobe of the lateral ones twice as narrow as the others. Stipules, which are the ſame at ſtem and leaflets, ſmall and ſubovate.

The ſeeds of this were brought from the Cape of Good Hope, and produced the plants in the ſtove of the Vienna garden.

4. Whole plant ſmooth: root annual: ſtem twining, ſubangular, and ten feet high: the intermediate leaflet oblong-lanceolate, attenuated into a point; in the lower part of the ſtem it is half a foot long or more: the lateral ones are in general ſhorter, and twice or thrice as wide at their internal baſe as at their external. The axillary racemes bear ſeveral ternate peduncles ſpringing from the ſame place. Flowers inelegant, with a concave greeniſh banner, and long, obtuſe concave wings, ſtretched out and whitiſh, as is the ſpirally-intorted keel. Legume oblong, compreſſed, acuminate, and bowed at the back. Seeds few, kidney-ſhaped, flat-compreſſed, blood-red on the circumference, white on the middle and lower part, and ſpotted with red points; and with a white hile. This blood-colour in the freſh ſeeds is ſcarlet.—Native, according to Linneus, of Africa[i].

5. Flowers roſe-coloured; ſeeds downy, appearing as if covered with meal; leaves angular, like thoſe of Ivy.—Native of the Eaſt Indies. Sherard had it from the Padua garden.

6. For the deſcription ſee *Dolichos trilobus*, *n.* 20.—It was introduced in 1777, by Sir Joſeph Banks; and flowers here in july[k].

7. Stipules looſe at the baſe and bifid. Peduncles ſmooth, the other parts hairy. Flowers few, ſeſſile, ſweet-ſmelling. Bractes two, very ſmall. Banner emarginate, wide, reflex, marked with lines on the inner ſurface: wings ſomewhat ſickle-ſhaped, having a lobe at the baſe on the right ſide diſtinct from the baſe itſelf; there being no lobe on the left ſide, the flower is oblique: keel ſickle-ſhaped, little oblique,

[a] Retzius [b] Gærtner. [c] Gerarde. [d] Ger. emac. [e] Raii hiſt. 884. [f] Linn. ſpec. [g] Loureiro. [h] Hort. kew. [i] Jacquin. [k] Hort. kew.

beaked, bifid at the tip. The plant is intermediate between this genus and Dolichos [k].

Stems five or six feet in height, the thickneſs of a ſtraw. Peduncles very long, bearing three or four flowers on ſhort pedicels, large, green before they open, afterwards whitiſh purple; as they fade the purple changes to pale violet, and finally to a duſky lurid colour, or yellowiſh brown; they do not laſt more than twenty-four hours: the banner is white or tinged with very pale purple, and has yellowiſh ſpots at the baſe, and ſlender ſtreaks towards the circumference; keel ſmall, curved in towards the banner, white or ſlightly tinged with purple; wings either rolled over each other, or bent in about the keel, of a darker purple colour. Legumes long, ſlender, browniſh. Seeds ſmall, blackiſh brown [l].

Native of the Weſt Indies. Cultivated in 1732, by James Sherard, M. D. at Eltham [m]: from ſeeds collected at the Havana, and ſent under the name of *Tryallos* [n].

8. Stems a yard and half and more in height, ſlender, round, not exceeding a ſtraw in ſize at bottom, of a brown or blackiſh purple colour, making few revolutions in twining. Petioles an inch long. Leaflets narrow, oblong, widening and as it were haſtate at the baſe, ſmooth, the veins ſcarcely viſible. Peduncles from the upper axils, very long, having two, narrow leaflets at the baſe, and at the top two or three flowers, without ſcent, the colour of pale red wine: banner ſhortiſh, not ſpreading, but bent towards the inner part; keel ſhort and narrow, twiſted into the banner; wings larger and ſpreading, marked with ſlender ſtreaks. Legumes ſlender, round, not hirſute, blackiſh brown when ripe. Seeds ſmall, turgid, of a blackiſh bay colour.

Native of Carolina, whence the ſeeds were ſent by a merchant of London, of the name of Tryan, with other rare plants. It flowered in auguſt, and the ſeeds ripened in ſeptember [o].

9. Stem upright, three feet high, twining only at top, round, ſomewhat ſtreaked and pubeſcent. Leaflets naked, blunt iſh, ſomewhat mucronate, the length of the petiole. Stipules ſomewhat enſiform. Peduncles a foot in length, ſtiff, upright. Spike thinner, in pairs, ſeſſile. Calyx cylindrical. Banner and keel paler; wings three times the ſize of the banner, convex, red, blueiſh at the baſe, converging; keel twiſted [p].

According to Jacquin the perianth is cylindric, greeniſh, narrow, ſmall, ſmooth and bilabiate. Banner greeniſh with a tinge of purple, and twice the length of the calyx. Wings blood-coloured, twice the length of the banner, roundiſh, concave, diſtant. Keel purple in the middle, white on each ſide, and on account of its convolution, ſhorter than the banner. Anthers yellow, oblong, and incumbent. Seeds ſeveral, oblong-reniform, ſmooth, brown, ſpotted with black. Legume linear, ſtraight, ſharp-pointed, and three or four inches long, brown, and rather roughiſh with decumbent hairs. Roots perfectly reſembling thoſe of other annual Phaſeoli, and not in the leaſt ſtrumoſe; for which reaſon Jacquin omits the ſynonyms of Dillenius and Plumier, quoted by Linneus in the Mantiſſa Plantarum, where the root is ſaid to be ſtrumoſe [q].

Native of the Weſt Indies. Introduced in 1781 by Mr. Francis Maſſon. It flowers in july [r].

10. Stems long, ſlender, green, round, ſtriated, ſubhirſute; joints from two to three inches diſtant. Leaves like thoſe of the common Kidney-bean, but ſmaller, finely hairy at their edges. Petioles an inch or an inch and half in length, thinly hairy. Peduncles from a hand to a ſpan in length, round, ſmooth, ſtriated, ſomewhat thicker than the ſtems. Flowers large, ſolitary or in pairs, without ſcent, at firſt purple, then violet: banner large, reflex, paler purple: wings broadiſh, ſtretched out, deeper purple; keel narrow, oblong, bent in towards the banner. Calycine ſegments four, the upper one larger than the reſt. Pedicel ſlender, very ſhort, purple. Legumes oblong, compreſſed, at firſt green, but brown and ſwelling more when ripe. Seeds twelve or more, ſmall, depreſſed, ſhining, of a browniſh red colour, with a white eye [s].

Dillenius does not mention its native place of growth, but Mr. Miller ſays that] the ſeeds were brought from Carolina.

11. This is a perennial plant with twining ſtalks riſing to the height of twelve or fourteen feet; the leaves are ſhaped like thoſe of the common Kidney-bean, but are ſmaller. The flowers are produced in ſlender ſpikes, they are of a purpliſh colour, and have an agreeable odour; they are ſucceeded by ſlender compreſſed pods, containing ſeveral oval compreſſed ſeeds.

Mr. Miller ſays it is a native of the Brazils. [According to Triumfetti, it was brought from Portugal to Italy, and it was not known from what country of India it came; it is more probable however that the Portugueſe had it from Braſil than from the Eaſt Indies.—It was cultivated in 1690, in the Royal garden at Hampton Court; and flowers in auguſt and ſeptember [t].

12. Stem herbaceous, ſtriated. Leaves alternate, ſmooth, ternate. Petioles and nerves at the back hairy. Leaflets petioled, deeply divided into three narrow-oblong ſharpiſh lobes, the lateral ones having commonly a ſhorter lobe on the outer ſide. Peduncles axillary, ſolitary, hairy, five-flowered. Flowers ſmall, with a wide banner, diſpoſed in a ſort of raceme. Deſcribed from a dried ſpecimen of Petiver's, communicated by Gronovius [u].

Native of the Eaſt Indies. Found in Tranquebar by Koenig. Alſo in Arabia by Forſkahl.

13. Root annual. Stem angular, hiſpid, from one to three feet high, flexuoſe, wrak, neither upright nor twining. Petioles long, hiſpid, compreſſed, channelled above, knobbed at the baſe. Stipules oblong, half-cordate, adnate, ciliate. Leaflets repand, acute, hiſpid on both ſides; the lateral ones obliquely ovate, the end one ovate-lanceolate; under the former one pair, and under the latter another pair of awl-ſhaped, ciliate ſtipules: partial petioles thicker than the common, darker, not channelled. Peduncles axillary, from two to three inches long, hiſpid, in a ſort of head, but it rarely happens that more than two of the flowers are fertile; each is knotted at the origin of the pedicels: theſe have ſtipules at the baſe reſembling the leaflets. Under the flower there is a ſmall, caducous, ciliate bracte; and two others, which are narrow, keeled, acuminate, ciliate, preſſed cloſe to the ſides of the calyx, and of the ſame length with it. Flowers dirty yellow, the upper part eſpecially of the banner being browniſh. Calyx ſmooth. Banner broad-cordate, having on the right ſide within a yellow callus or bump impreſſed from without, and when folded together ſickle-ſhaped. Wings yellow. Keel dirty yellow, leſs twiſted than in the other ſpecies. Legumes ſpreading, cylindrical, hiſpid, ſcarcely toruloſe. Seeds ſubcylindrical, ſhort green.—It grew from ſeeds ſent from Conſtantinople by Celſing [x].

14. Stem ſhrubby, long, branched. Stipules two-horned, acute, ſpreading. Leaves ternate, large. Flowers wholly yellow in ſubterminating racemes. Calyx four-cleft; ſegments equal in length; the upper one blunt and emarginate. Legumes ſomewhat compreſſed, long, not eſculent. The root is large and eſculent.—Native of Cochinchina.

15. Stem annual, ſhort. Leaves ternate: leaflets ſmooth and flat. Flowers white, in axillary racemes. Legume ſomewhat creſcent-ſhaped, compreſſed, even, pendulous, containing three ovate ſeeds, pale variegated with red and eatable.—Native of Tunquin, and cultivated in Cochinchina [y].

16. This ſpreads out wide, and ſupports itſelf without any prop. Leaves ternate, large, ſoft and veined. Flowers white. Seeds white with the eye black. It

[k] Linn. ſpec. [l] Dillenius. [m] Hort. kew. [n] Dillenius. [o] Idem. [p] Linn. mant. [q] Jacquin. [r] Hort. kew. [s] Dillenius. [t] Hort. kew. [u] Jacquin. [x] Retzius. [y] Loureiro.

is ſown in great abundance in the fields of Italy in the month of may[x]: but it is a native of the Eaſt Indies.

Retzius remarks, that the character taken from the relative ſize of the bractes is very uncertain; they being in ſome varieties larger, in others leſs than the calyx.

17. Stem annual, upright, two feet high, ſubcylindrical, grooved, hairy, branched. Leaves ternate, broad-lanceolate, hairy; ſtipules in pairs, acute; petioles long. Flowers duſky yellow, on a long upright common peduncle. Calyx four-cleft, acute, equal; the upper legment emarginate. Banner large, roundiſh, ſpreading, plaited and emarginate at the tip: wings ſhorter, broad-ſickle-ſhaped, with a conical inflated lobe, prominent outwards: keel ſickle-ſhaped, of a length between the banner and wings. Legumes narrow, ſtraight, acuminate, hairy, brown. Seeds many, greeniſh-yellow, ovate, ſmall[y]. Thunberg obſerves, that it varies with white, and with black ſeeds.

Native of Ceylon, Amboina, China, Cochinchina and Japan.

18. Stem and leaves rigid. Flowers pale or greeniſh yellow. Legume thick, ending in a beak that is curved inwards. Seeds black, the ſize of Coriander. *Mexi* is the Spaniſh name.

Native of India. Cultivated in the Apothecaries botanic garden at Cheſſea, in 1758. It flowers in june and july[z].

19. Stem upright, ſcarcely ſcandent. The whole plant is covered with hairineſs of a colour like red wine. The lateral leaflets are half-cordate on the outer ſide, lanceolate on the inner. Stipules of the leaves oval-oblong, adnate as far as the middle, naked, ciliate. Stipules of the leaflets lanceolate, narrowing into a briſtle. Peduncles the length of the leaves, terminated by an ovate ſmooth receptacle, bearing ſeſſile yellow flowers in a head[a].

Stem a foot and half high, branched. Leaflets roundiſh, ſomewhat acute both ways, hairy, ſoft, yellowiſh-green. Stipules bifid, acute. Common peduncle nearly equal to the petiole, ending in a three or four-flowered head. Calyx five-cleft, ſupported by two incurved, inflected ſtipules, longer than the calyx. The keel putting forth a tubular little horn from one ſide, removes one of the wings, whilſt the other wing, with the keel and ſtamens is twiſted into a ſpiral. Legume round, ſlender, longiſh, acuminate. Seeds many, ſubovate, browniſh green, eſculent[b].

Native of the Eaſt Indies, China and Cochinchina.

20. Stem ſomewhat ſhrubby at bottom, from one to two feet high, branched, ſtiff, round, ſmooth, brown. Branches ſimple, upright, round, ſmooth. Leaves ternate: leaflets oblong, acuminate; the two lateral ones ſubſeſſile, entire, veined, ſmooth above, pubeſcent underneath. Petioles alternate, erect, ſtiff, channelled, angular, reddiſh. Stipules at the baſe of the petioles, oppoſite, acuminate: others at the baſe of the leaves. Peduncles long, faſtigiate, many-flowered, round, pubeſcent. Flowers in a ſort of ſpike, alternate, moſtly in pairs cloſe together, blood-red: banner of a paler red; wings deep red, twice as large as the banner; keel whiteiſh. Legume roundiſh, awl-ſhaped. Seeds roundiſh, ſeparated, brown.

Native of Jamaica in moiſt ſandy grounds[c]. Common in the Savannas about Spaniſh Town[d].

21. Stem about a foot high, branched. Petioles three or four inches long. The odd leaflet is an inch and half broad at the baſe, two inches and a half long, on a petiolule three quarters of an inch longer than the lateral leaflets, which are ſmaller; they are all very ſoft, and of a yellowiſh green colour. Peduncles axillary, ſtrong, nine inches in length. Corolla white. Legumes three or four inches long, almoſt round and ſtraight, clay-coloured. Seeds very many, almoſt round, white with a black eye, not ſo big as the ſmalleſt field pea. They are accounted the ſweeteſt and beſt food of any of the Kidney-beans[e].—Native of both Indies.

[x] Marſhall. [y] Loureiro. [z] Hort. kew. [a] Linn. mant. [b] Loureiro. [c] Swartz. [d] Browne. [e] Sloane.

Ray has enumerated 119 ſpecies of Phaſeolus, namely 31 in the firſt volume of his Hiſtory, and 88 in his third volume or Supplement; beſides ſome Braſilian ſorts from Piſo, and Ph. Caracalla, in the Appendix to his ſecond volume. Doubtleſs many of theſe are varieties; and many do not belong to this genus; the genus Dolichos not being conſtituted in his time.]

PROPAGATION AND CULTURE.

Kidney-beans for the table.

The three ſorts which are uſually cultivated for early crops, are the ſmall white Dwarf, the Dwarf black, which is called the Negro-bean, and the Liver-coloured Bean. The ſtalks of theſe never being very long, may be planted much nearer together than the larger growing kinds, and they require but little ſupport; theſe are planted on hot-beds under frames, or in pots which are placed in ſtoves, to come early in the ſpring, for which purpoſe they are better adapted than any of the other; but they are not to be compared with ſome of the others for goodneſs, but as they may be had at a time when the others cannot be ſo well obtained, they are generally cultivated in gardens; and where there are not the conveniences of ſtoves or frames for raiſing them very early, they are planted in warm borders near hedges, walls, or pales, where they will be fit for uſe a fortnight earlier than the other ſorts.

The next to theſe are the Batterſea and Canterbury Kidney-beans; theſe do not ramble far, and producing their flowers near the root, bear plentifully for ſome time: the Batterſea Bean is the forwarder of the two, but the other will continue bearing much longer; they are both better flavoured than any of the three former ſorts, but when they begin to be large are very ſtringy and rough.

There are two or three ſorts of Kidney-beans cultivated with erect ſtalks, which want no ſupport, as they do not put out any twining ſtalks; theſe are much cultivated by the gardeners for that reaſon, as alſo for their producing a great plenty of pods; but they are inferior in goodneſs to all the other, eſpecially that ſort with black and white ſeeds, whoſe pods have a rank flavour, and, when boiled, become ſoft and mealy; ſo this ſhould never be propagated by perſons of taſte.

The beſt ſorts for the table are the ſcarlet Bloſſom-bean before-mentioned, and a white Bean of the ſame ſize and ſhape, which appears to be only a variety of the ſcarlet, as it differs in no other reſpect but the colour of the flowers and ſeeds, being equal in ſize and flavour. And next to theſe is the large Dutch Kidney-bean, which grows as tall as either of theſe, ſo muſt be ſupported by ſtakes, otherwiſe the ſtalks will trail upon the ground and ſpoil. The ſort with ſcarlet flowers is preferable to this in goodneſs, and is alſo hardier; and although it will not come ſo early as ſome of the dwarf kinds, yet as it will continue bearing till the froſt puts a ſtop to it in the autumn, it is much preferable to either of them; for the pods of this ſort when old, are ſeldom ſtringy, and have a better flavour than the young pods of thoſe ſorts, and will boil greener; and where this is ſown in the ſame ſituation and ſoil as the Batterſea-bean, it will not be a fortnight later.

All the ſorts of Kidney-beans are propagated by ſeeds which are too tender to be ſown in the open air before the middle of april; for if the weather ſhould be cold and wet after they are in the ground, they will ſoon rot; or if the morning froſts ſhould happen after the plants come up, they will be deſtroyed; therefore the beſt way to have early Kidney-beans, where there is no conveniency of frames for raiſing them, is to ſow the ſeeds in rows pretty cloſe upon a moderate hot-bed, the latter end of march, or the beginning of april. If the heat of the bed is ſufficient to bring up the plants, it will be enough; this bed ſhould be arched over with hoops, that it may be covered with mats every night, or in bad weather. In this bed the plants may ſtand till they have put out their trifoliate leaves, then they ſhould be carefully taken up, and tranſ-

planted in warm borders near hedges, pales or walls. If the ſeaſon proves dry at the time of removing them, the plants ſhould be gently watered to forward their taking new root, and afterward they muſt be managed in the ſame way as thoſe which are ſown in the full ground. Theſe tranſplanted Beans will not grow ſo ſtrong as thoſe which are not removed, nor will they continue ſo long in bearing, but they will come at leaſt a fortnight earlier than thoſe which are ſown in the full ground.

The firſt crop intended for the full ground, ſhould be put in about the middle of april; but theſe ſhould have a warm ſituation and a dry ſoil, otherwiſe the ſeed will rot in the ground; or if the weather ſhould prove ſo favourable as to bring up the plants, yet there will be danger of their being killed by morning froſts, which frequently happen the beginning of may.

The ſecond crop, which ſhould be one of the three large ſorts laſt mentioned, ſhould be ſown about the middle of may. Theſe will come into bearing before the early kinds are over, and if they are of the ſcarlet ſort, will continue fruitful till the froſt deſtroys the plants in the autumn, and theſe will be good as long as they laſt. The manner of planting them is to draw ſhallow furrows with a hoe, at about three feet and a half diſtance from each other, into which you ſhould drop the ſeeds about two inches aſunder; then with the head of a rake draw the earth over them, ſo as to cover them about an inch deep.

If the ſeaſon is favourable, the plants will begin to appear in about a week's time after ſowing, and ſoon after will raiſe their heads upright; when the ſtems are advanced above ground, you ſhould gently draw a little earth up to them, obſerving to do it when the ground is dry, which will preſerve them from being injured by ſharp winds; but you ſhould be careful not to draw any of the earth over their ſeed-leaves, which would rot them, or at leaſt greatly retard their growth. After this, they will require no farther care but to ſtick them when the plants begin to run, and to keep them clear from weeds until they produce fruit, when they ſhould be carefully gathered two or three times a week; for if they are permitted to remain upon the plants a little too long, the Beans will be too large for eating, and the plants would be greatly weakened thereby.

The large ſorts of Kidney-bean muſt be planted at a greater diſtance, row from row; for as theſe grow very tall, if the rows are not at a greater diſtance, the ſun and air will be excluded from the middle rows, therefore theſe ſhould not be leſs than four feet diſtance row from row; and when the plants are about four inches high, the ſtakes ſhould be thruſt into the ground by the ſide of the plants, to which they will faſten themſelves, and climb to the height of eight or ten feet, and bear plenty of fruit from the ground upward. The Dutch and French preſerve great quantities of the large Dutch Beans for winter uſe, which they ſtew, and make good with gravy and other ſauces.

There are ſome perſons who raiſe theſe in hot-beds, in order to have them early. The only care to be taken in the management of theſe plants when thus raiſed, is to allow them room, and give them as much air as can be conveniently when the weather is mild, as alſo to let them have but a moderate heat; for if the bed is over hot, they will either burn or be drawn up ſo weak as ſeldom to come to good.

The manner of making the hot-bed being the ſame as for Cucumbers, &c. need not be repeated in this place; but only obſerve, when the dung is equally levelled, to lay the earth about four or five inches thick, and let the great ſteam of the bed paſs off before you ſow the ſeeds. The time for doing this muſt be proportioned to the ſeaſon when you would have the Beans for the table, but the fureſt time for a crop is about a week in february.

The manner of ſaving the ſeeds of theſe plants is to let a few rows of them remain ungathered in the height of the ſeaſon; for if you gather from the plants for ſome time, and afterwards leave the remaining for ſeed, their pods will not be near ſo long and handſome, nor will the ſeed be ſo good. In autumn, when you find they are ripe, you ſhould in a dry ſeaſon pull up the plants, and ſpread them abroad to dry; after which you may threſh out the ſeed, and preſerve it in a dry place for uſe.

[For forward crops of dwarf Kidney-beans, the early white and negro ſorts are the beſt and bear the longeſt. For the main crop, the ſpeckled, Batterſea and Canterbury dwarfs are to be preferred, theſe being plentiful bearers and of long continuance.

To have a regular ſupply of theſe from the middle or end of june to october, they ſhould be ſown from the middle of april to the middle or end of july, every fortnight or three weeks.

For the firſt crop the ſoil muſt be dry and light, the ſituation warm and ſheltered, the drills drawn north and ſouth. The other crops are better in the open quarters. When the weather is very dry, the Beans to be ſown ſhould be ſoaked ſome hours in water, or the drills may be well watered immediately before the Beans are put in.

The climbing ſorts or runners are not fit for early crops, but principally for ſummer and autumn from july to michaelmas, or till froſts put an end to them. The firſt or ſecond week in may is early enough to put in the firſt crop of theſe; and the ſecond may be planted any time in june. Two crops will furniſh an abundant and conſtant ſupply.

Dwarf Kidney-beans by artificial heat.

To have early Kidney-beans, they may be forwarded in a very moderate hot-bed at the end of march, and planted out, when they are an inch or two high, and the weather is favourable, in a warm border. They may be ſown on the ſurface in the hot-bed, or in large pots; but it is beſt to put them in ſmall pots, three in each pot, becauſe they may be turned out for tranſplantation, with the ball of earth about their roots, and thus be ſcarcely ſenſible of their removal. They muſt however be gradually inured to bear the open air, by taking off the covering whenever the weather is mild, and expoſing them by degrees; refreſhing them frequently with water, when they cannot have the benefit of warm ſhowers.

After they are tranſplanted they ſhould be well watered to ſettle the earth to their roots; and it will much forward their growth, if they are covered occaſionally with hand glaſſes, when the nights are cold.

After all, this crop will come into bearing only a fortnight ſooner than plants ſown in the natural ground.

But to produce Kidney-beans for the table in april and may, or perhaps towards the end of march, they muſt be raiſed and continued in a hot-bed, which muſt be made by the middle or end of february. When the heat and ſteam are abated, and the bed is covered ſix or eight inches thick with mould, ſow the ſeeds of one of the ſmall early dwarf ſorts in drills fifteen or eighteen inches aſunder, an inch deep, and two or three inches apart; give them air and refreſh them with water in fine weather. When they are fully grown, if they preſs much againſt the glaſſes, raiſe them at bottom to give the plants room to grow freely.

Or they may be raiſed on a very moderate hot-bed in december or january; and removed, when of a proper ſize into another hot-bed made as directed for Cucumbers; only the dung need not be ſo thick, leſs heat being required. When this bed is of a moderate warmth, lift the plants out of the other with a trowel, leaving as much earth about their roots as you can, and plant them at fourteen inches diſtance row from row, and four inches plant from plant. Give them a moderate watering, but afterwards be ſparing of it; ſhade the beds from noon till the ſun is near off, and give them air whenever the weather is mild. The frames ſhould be two feet high in the back, ſloping to fifteen inches in front, and the bed ſhould be four feet broad.

In hot-houſes or ſtoves early Kidney-beans may be had at almoſt any time with eaſe, by raiſing them in pots or long narrow boxes. The beſt ſorts for this purpoſe are the early white, liver-coloured or ſpeckled dwarfs. The pots or boxes filled with rich light earth

may be placed upon the top of the wall which surrounds the bark-bed, or upon shelves in any convenient part of the house. When the seeds begin to sprout moisten the mould, and when they are grown up water them frequently, or at least three times a week. Where room is wanting, the seeds may be set in small pots, and transplanted into larger ones for fruiting.]

The seeds of the more tender sorts of *Phaseolus*, which are cultivated for curiosity or ornament, should be sown in a moderate hot-bed in the spring; and when the plants come up, they must be carefully transplanted into pots filled with light fresh earth, and plunged into a hot-bed to facilitate their taking root; after which they should be inured to bear the open air by degrees, and may be removed into it at the end of june or beginning of july, in a sheltered situation. As they advance in growth, the perennial sorts must be removed into larger pots.

Some that are less tender may be sown on a warm border at the end of april; and when the plants run up, they must be supported.

Stem almost naked, leaves bipinnate.

DESCRIPTIONS, &c.

1. Root biennial. Radical fibres abundant, placed in whorls at the lower joints of the stem, which they support by rooting in the mud. Stem curved at bottom, and then upright, hollow and hydraulic, four inches in thickness, smooth, striated or slightly grooved, branched, distorted, three or four feet in height. Branches divaricating. Leaves very large, triply pinnate, bright green, smooth: pinnas multifid, ovate, gash-toothletted; pinnules semipinnate, the last lobules a little wider than the nerve, lanceolate, blunt: both pinnas and pinnules branching at obtuse angles with the nerves. Petioles arising from a sheath, fistular, not keeled. Sheaths wide, augmented by a white membrane, embracing the stem. Universal umbel drooping, composed of seven, eight or nine or more unequal rays: partial closer, with a many-leaved involucre; leaflets lanceolate, linear or bristle-shaped. Proper perianth very small. Corolla small, white: petals little unequal. Fruit crowned with the little five-toothed perianth, oblong, smooth, with five red streaks[1].

Native of most parts of Europe, by the side of rivers, ditches and ponds, where there is mud, flowering in june and july.

Linnæus informs us, that the horses in Sweden, by eating this plant are seized with a kind of palsey; hence Withering and Sibthorp have named it *Horse-bane*. This effect however is not to be ascribed to the plant, but to a coleopterous insect breeding in the stalks, which he therefore names *Curculio paraplecticus*. In the winter, the roots and stem, dissected by the influence of the weather, afford a curious skeleton or net-work[2]. The leaves are sometimes added to discutient cataplasms; and for this purpose Boerhaave speaks highly of it. The seeds are recommended in intermittents, and are said to be diuretic, antiseptic and expectorant. The dose is from one to three drams daily[3].

The seeds, when taken in large doses, produce a sensation of weight in the head, accompanied with giddiness. They manifest an aromatic acrid taste, approaching to that of Lovage. Distilled with water, they yield an essential oil, of a pale yellow colour, and a strong penetrating smell. One pound of the seeds affords an ounce of watery extract, but nearly double this quantity of spirituous extract, of which more than three drams consists of resin[4].

The efficacy of this plant rests chiefly on the testimonies of Ernstingius and Lange, by whom various cases of its successful use are published, especially in wounds and inveterate ulcers, and even in cancers; also in phthisis pulmonalis, asthma, dyspepsia and intermittent fevers[5].

Dr. Woodville rightly observes, that though the disorders here noticed are so dissimilar as to afford no satisfactory evidence of the medicinal qualities of these seeds, yet they appear to be well deserving of farther investigation.

β. In running streams the leaves become divided, like those of *Ranunculus aquatilis*, in the same situation. Dillenius remarked it between Woodstock and the Duke of Marlborough's bridge at Blenheim, in such abundance as to stop the course of the stream. Also in Hackney river[6]. Sometimes, though rarely, according to the remark of Mr. Relhan, when the plant grows in an angle, out of the rapid course of the stream, it produces its flowers.

[1] Krocker, Haller, Pollich. [2] Linn. suec.

[6] Ray syn. & Withering.

2. Root

2. Root thick, branched, the head crowned with briſtles. Stems a foot high or leſs. Leaves hardiſh, bright green, more in length than breadth; pinnules ſemipinnate, the ultimate ſegments flat, very ſharp, ſimple, two-lobed and three-lobed. Petals commonly purple, unequal. Fruit ſemioval, large, ſurrounded with a ſort of circle, with ridges ſo large as that it is almoſt winged [a].

Linnæus remarks, that it has the leaves of *Chærophyllum*; and that the involucrets are of the ſame length with the umbellets. Scopoli—that in the Alps it is a ſmall plant; but becomes three times as big in a garden; and has the fruit crowned with a conſiderable calyx, but not with a circle. Haller ſays, that it has a very aromatic ſmell.

Native of Siberia, Auſtria, Carniola and Switzerland. Haller informs us, that the goodneſs of the Alpine paſtures is eſtimated by the abundance of this plant. I found it in flower, in auguſt 1779, as I paſſed over the Col de Balme.

It was introduced here in 1774, by the Doctors Pitcairn and Fothergill [b].

DESCRIPTIONS, *&c.*

1. The common or white Syringa or Mock Orange is a ſhrub that ſends up a great number of ſlender ſtalks from the root, ſeven or eight feet in height, having a gray bark, and putting forth ſeveral ſhort branches from their ſide. Leaves ovate or ovate-lanceolate; thoſe upon the young ſhoots three inches and a half long, and two broad in the middle, terminating in acute points, and having ſeveral indentures on their edges; they are rough and of a deep green on their upper ſide, and pale on their under; ſtand oppoſite upon very ſhort foot-ſtalks, and have the taſte of freſh Cucumbers. The flowers come out from the ſide, and at the end of the branches, in looſe bunches, each on a ſhort pedicel; they are white, and have a ſtrong ſcent, which at ſome diſtance reſembles that of Orange-flowers; but near, it is too powerful for moſt perſons. The flowers appear at the end of may, and continue great part of june: [this year 1799, they did not open till towards the end of june.] This ſhrub ſeldom produces ſeeds that ripen in this country.

[The primary flower is five-cleft in the calyx, corolla, piſtil and capſule; the reſt are four-cleft [c]. The ſtyle in the flowering calyx is four-cleft at the tip only, but in the ſeeding calyx it is cloven to the very baſe [d]. The leaves are ſtrongly nerved underneath, and are very irregularly toothed. In a large parcel of the flowers which I have before me, there is only one which has five petals, and the fifth is very narrow and ſmall.

Native probably of the South of Europe, though no place is aſſigned in any of the local Floras where it is found really wild. Linnæus ſays, but with a doubt, about Verona. Ray obſerved it near Mont Saleve in Savoy, far from any houſe, but did not dare to pronounce it wild there. Haller and Krocker ſpeak of it only as a denizon, and Allioni as of exotic origin. Villars ſays it is not indigenous of Dauphiné, though it is found in hedges far from habitations.—It was cultivated in 1597 by Gerarde [e].]

β. Dwarf Syringa ſeldom riſes above three feet high. The leaves are ſhorter, more ovate, and little indented on their edges. The flowers come out ſingly from the ſide of the branches, and have a double or treble-row of petals of the ſame ſize and form as the other, and the flowers have the ſame ſcent; but flowering very rarely, it is not much eſteemed.

γ. Philadelphus inodorus, or Carolina Syringa riſes with a ſhrubby ſtalk about ſixteen feet high, ſending out ſlender branches from the ſides, oppoſite to each other. Leaves ſmooth, ſhaped like thoſe of the Pear-tree, entire, oppoſite, on pretty long foot-ſtalks. The flowers are produced at the ends of the branches; they are large but without ſcent; each has four white oval petals ſpreading open, and a large calyx compoſed of four acute-pointed leaflets. Capſules oval, filled with ſmall ſeeds.

[Humphry Marſhall, in his American Grove, gives us no information concerning this ſhrub; having only copied Mr. Miller's deſcription, by which it does not ſeem to differ materially from the common ſort.

2. Stem arboreous, very much branched, almoſt upright, full of chinks, aſh-coloured; branches diffuſed, oblique, ſubfaſtigiate, round, leafleſs, the upper ones rod-like, leafy, herbaceous at the top, ſilky-

[a] Haller. [b] Hort kew. [c] Linn. [d] *Munch. hoſt. n.* 401. [e] Hort. kew.

villoſe.

villose. Leaves alternate, scattered, subsessile, acute, spreading, flat, even, dotted, dark green above, pale underneath. Petioles scarcely any, flattish. Flowers solitary, terminating, sessile, white, the size of Cherry-blossoms. Bractes roundish, imbricate, concave, deciduous, surrounding and covering the calyx to the middle. Perianth hemispherical, growing to the germ; the margin quite entire and elevated: segments small, ovate, concave, alternate with the petals, white, on the outside red. Petals five, orbiculate, spreading very much, flattish, inserted by a very small claw into the inner margin of the calyx, and three times as long as the leaflets of it. Filaments twenty-four, erect, half the length of the petals, inserted in a single row into the edge of the calyx. Anthers twin, roundish. Germ hemispherical, umbilicated by the calyx, somewhat convex above. Style of the same length and in the same direction with the stamens, deciduous. Capsule excavated at top, five-streaked, five-celled, five-valved, gaping at top. Seeds linear, cylindric, very slender.

Native of New Zealand, where the fresh flowering shoots were used as tea by the sailors in Captain Cook's voyage. They found the infusion sweetly aromatic and fragrant, in a short time however it became very bitter. It was supposed to be serviceable in the sea scurvy[1].—It was introduced here in 1772, and flowers in june and july[2].

3. This also is a native of New Zealand, where it was found, with the preceding, by Sir Joseph Banks. It was introduced with that in 1772, and flowers in july and august.

4. Native of New South Wales. Introduced in 1774, by Tobias Furneaux, Esq. It flowers in june and july[2].]

PROPAGATION AND CULTURE.

1. Common Syringa is extremely hardy, and will thrive in almost any soil or situation, but will grow taller in light good ground, than in that which is stiff. It is usually propagated by suckers, which are sent from the roots in great plenty. These should be taken from the old plants in autumn, and planted in a nursery, to grow one or two years till they have obtained strength, and then they may be transplanted to the places where they are designed to remain. They are commonly disposed in plantations of flowering shrubs, among others of the same growth. [The Syringa mixes very well with the Lilacs, Gelder Rose and Laburnum; and is particularly valuable from its thriving under the shade of trees, and forming a blockade against low buildings, where persons have no objection to the powerful odour.

It may be increased by cuttings, planted in october in a moist shady border: and by layers, from young twigs put into the ground at the beginning of winter; these will be rooted by the autumn following.

The other species may be increased in the same ways, but are too tender to bear the open air in our climate.]

Leaves ovate-oblong ſubcordate ſerrate.

DESCRIPTIONS, *&c.*

[The three species of Phillyrea are distinguished by the form and indentations of their leaves. In the first these are lanceolate inclining to oblong, ovate, or oval, of an intermediate breadth between the two others, whence its trivial name; they are sometimes serrate, sometimes the serratures are very few, and sometimes there are none. In the second, the leaves are narrower, of a linear form, inclining more or less to lanceolate, and quite entire about the edges. In the third, they are wider, of an ovate form, more or less inclining to oblong or lanceolate, and serrate.

These shrubs are natives of the Southern countries of Europe; are Evergreens, and frequently confounded with the *Alaternus*. That however has the leaves placed alternate on the branches, whereas in this they are opposite: that also has five stamens, and this has only two, to each flower.]

1. This

1. This riſes to an equal height with the third ſort, which is commonly called the True Phillyrea; but the branches are more diffuſed, and have a darker bark: the leaves are of a darker green, are more than two inches long, and almoſt an inch and half broad, a little ſerrate on their edges, oppoſite on ſhort foot-ſtalks. Flowers axillary, in long bunches, of an herbaceous white colour.

Mr. Miller has two other ſpecies, which are varieties of this, namely the *Privet-leaved* and *Olive-leaved*. Theſe are of humbler growth, ſeldom more than eight or ten feet high.

The branches of the *Privet-leaved* are weaker, and ſpread wider, and are covered with a light brown bark. The leaves are ſtiff, almoſt two inches long, and half an inch broad in the middle, drawing to a point at both ends, and ſit cloſe to the branches. Flowers in little axillary cluſters, ſmall and whiter.

In the *Olive-leaved*, the branches are ſtronger, and ſpread out wider; the bark is of a lighter colour; the leaves are ſtiff, ſmooth and entire, on very ſhort foot-ſtalks, of a lucid green, and terminating in a point. Flowers in cluſters, on pretty long peduncles, from the axils of the young branches, ſmall and white.

[In Mr. Aiton's catalogue of the Royal garden at Kew, where this genus is very accurately detailed, two other varieties are added, namely the *Long-branched*, with long upright branches; and the *Drooping*, with the branches hanging down and ſtraddling.

According to Gærtner, the fruit is a ſuperior berried Drupe, of a black colour, and terminated by the globular ſtigma: the rind fleſhy, but thin: the ſhell papery, very thin, white and two-celled. Seeds one in each cell, but one of them commonly abortive, ovate, ſlightly acuminate at top, convex on one ſide, flattiſh or angular on the other, ſomewhat wrinkled, of a ruſeſcent bay colour, faſtened to the partition.]

2. Stalk ten or twelve feet high, ſending out oppoſite branches, covered with a brown bark ſpotted with white. Leaves ſmooth, ſtiff, narrow, entire, ſeſſile, about an inch and half long, and half an inch broad in the middle, drawing to a point at both ends, of a light green and pointing upwards. The flowers come out in large cluſters at each joint of the branches, ſitting cloſe like whorled flowers, and almoſt ſurrounding them; they are ſmall and white.

Roſemary-leaved Phillyrea (n. 7. of Miller) is a variety of this. It is of humbler growth, ſeldom riſing more than four or five feet high, ſending out ſlender, oppoſite, ſtraight, branches, ſparſedly diſpoſed. Leaves dark green, ſtiff and entire; about an inch long, and not more than an eighth of an inch broad, ſeſſile. Flowers ſmall, white, in cluſters from the ſide of the branches. Berries very ſmall, rarely ripening in England.

[The Kew catalogue adds another variety under the name of *brachiata* or *Dwarf Phillyrea*.]

3. The true Phyllyrea, ſo called to diſtinguiſh it from the Alaternus, which the gardeners call ſimply Phillyrea; or the *Smooth broad-leaved Phillyrea*, riſes with a ſtrong upright ſtem to the height of eighteen or twenty feet, dividing into ſeveral branches, covered with a ſmooth grayiſh bark. Leaves entire (or obſcurely ſerrate), firm, of a light green, an inch and half long, and an inch broad, on ſhort foot-ſtalks. Flowers axillary, on each ſide, of an herbaceous white colour, in ſmall cluſters; they come out in march, and being ſmall make no great appearance.

Prickly broad-leaved Phillyrea is a variety of this. It is as high as the ſmooth one, and ſends out ſeveral ſtrong branches, which grow erect, and are covered with a gray bark. Leaves an inch and half long, and an inch broad, firm, of a lucid green, and ſerrate, each ſerrature ending in a ſpine.

[Mr. Aiton adds another variety, under the name of *obliqua*, or *Ilex-leaved Phillyrea*.

Theſe ſhrubs were cultivated very early in our gardens. Gerarde ſays that he planted them at Barne Elmes near London, belonging to the right honourable the Earl of Eſſex, and that he had them growing in his own garden likewiſe.]

PROPAGATION AND CULTURE.

Theſe ſhrubs are hardy enough to thrive in the open air in England, and are never injured except the winters are very ſevere, which ſometimes cauſes their leaves to fall, and kills a few of the weaker branches, but theſe are repaired by new ſhoots the following ſummer; ſo that there are but few of the evergreen-trees which are hardier than theſe, or that deſerve more to be cultivated for pleaſure.

Formerly theſe were either planted againſt walls, to which they were trained to cover them; or if they were placed as ſtandards, their branches were ſheared either into balls or pyramids, like moſt of the evergreen-trees; ſo that when the former old taſte of laying out gardens was exploded, the evergreens were generally baniſhed; and for ſome years there were but few ſorts cultivated, whereby ſeveral valuable kinds of evergreen-trees were almoſt entirely loſt in England, and have been with difficulty retrieved ſince; in the manner which the evergreen trees and ſhrubs are now diſpoſed in gardens, they have a very fine effect, eſpecially during the winter ſeaſon, when the other trees are deſtitute of leaves.

The firſt, third and prickly broad-leaved ſorts are very proper to intermix with other evergreen-trees of the ſame growth, to form clumps in parks, or to plant round the borders of woods; which are filled with deciduous trees, where in the ſummer time, the dark ſhade of theſe evergreens will make a fine contraſt with the brighter green leaves of the deciduous trees; and in winter, when the latter are deſtitute of leaves, they will have a fine effect, and will be a harbour for birds. Theſe may be trained up to ſtems, ſo as to be out of the reach of cattle, therefore may be planted in open places, where, if they are fenced againſt cattle till they are grown up, they may be afterwards expoſed.

The others, which are of humbler growth, muſt be confined to gardens or other incloſures, where they may be ſecured from cattle, hares, rabbets, &c. otherwiſe they will be ſoon deſtroyed.

Theſe plants are propagated either from ſeeds or layers, but the latter being the moſt expeditious method in England, is chiefly preferred. The beſt time to lay them down is in autumn, when you ſhould dig the ground round the ſtems of the plants intended to be layed, making it very looſe; then making choice of a ſmooth part of the ſhoot, you ſhould make a ſlit upward (in the manner as is practiſed in laying of Carnations) and then bend the branch gently down to the ground, making a hollow place with your hand to receive it; and having placed the part which was ſlit into the ground, ſo as that the ſlit may be open, you ſhould faſten it down with a forked ſtick that it may remain ſteady, covering that part of the branch with earth about three inches thick, obſerving to keep the upper part erect. You muſt keep them clear from weeds the ſpring and ſummer following, which, if ſuffered to grow up amongſt them, will prevent their taking root.

The autumn following moſt of theſe plants will be rooted, at which time they may be taken off, and carefully planted in a nurſery, where they may be trained up three or four years in the manner you intend them to grow; during which time dig the ground between the rows, and cut about the roots of the plants every year, which will cauſe them to ſtrike out ſtrong fibres, ſo as to ſupport a good ball of earth when they are removed; alſo ſupport their ſtems with ſtakes, in order to make them ſtraight, otherwiſe they are very apt to grow crooked and unſightly.

When the plants have been thus managed three or four years, tranſplant them into the places where they are deſigned to remain. The beſt time for this work is the end of ſeptember, or the beginning of october; but in removing them, dig round their roots, and cut off all downright or ſtrong roots, which have ſhot out to a great diſtance, that you may the better preſerve a ball of earth to each plant, otherwiſe they are ſubject to miſcarry; and when you have placed them in their new quarters, lay ſome mulch upon the ſurface of the ground to prevent its drying. You ſhould alſo

ſupport the plants with ſtakes, until they have taken faſt hold of the earth, to prevent their being turned out of the ground, or diſplaced by the winds, which will deſtroy the fibres that were newly put out, and greatly injure the plants. Theſe trees delight in a middling ſoil, which is neither too wet and ſtiff, nor too dry, though the latter is to be preferred to the former, provided it be freſh.

Thoſe ſorts with ſmall leaves are commonly two years before they take root when laid, therefore they ſhould not be diſturbed, for the raiſing them out of the ground greatly retards their rooting.

If theſe plants are propagated by ſeeds, they ſhould be ſown in the autumn ſoon after they are ripe, for when they are kept out of the ground till ſpring, they do not grow the firſt year. The ſeeds will do beſt if they are ſown in pots or boxes filled with light loamy earth, and placed under a garden frame where they may be ſcreened from hard froſt, but always expoſed to the open air in mild weather. If the ſeeds are ſown early in the autumn, the plants will appear in the ſpring; but if they ſhould not come up, the pots ſhould be plunged into the ground in an eaſt border, where they may only have the morning ſun, in which ſituation they ſhould remain the following ſummer: during which time they may be conſtantly kept clean from weeds, and in the autumn removed again under a frame for ſhelter in winter, and the ſpring following the plants will certainly come up, if the ſeeds were good. Towards the middle of april, the pots ſhould be again plunged into the ground on an eaſt border, to prevent the air from drying the earth through the pots, which is generally the caſe when the pots ſtand upon the ground; ſo that they muſt then be frequently watered, which ſhould not be practiſed to theſe plants where it can be avoided. The michaelmas following the plants ſhould be carefully taken out of the pots, and planted in a nurſery-bed, covering the ſurface with old tan to keep out the froſt; and if the winter prove ſevere, they ſhould be covered with mats, afterwards they may be treated as the layers.

Garciana cochinchinenſis. *Lour. cochinch.* 15. *ed. Willd.* 20.

DESCRIPTION, *&c.*

Root perennial. Stem two feet high, herbaceous, quite ſimple, ſpongy, upright, round, woolly. Leaves awl-ſhaped, thick, woolly, upright. Racemes long, upright, terminating. Flowers peduncled, golden, ſupported by ſhort acuminate hirſute ſpathes*. Capſule ſuperior, woolly, with the valves having the partition in the middle. Seeds extremely minute, ſubcylindric, rugged all about with irregular tubercles, of a duſky ferruginous colour, at top blunt, and as it were capped, at bottom lengthened out into a membranaceous, pale whitiſh, deeply concave umbilicus; they are faſtened in a horizontal ſituation into the central thickened rim of the partitions*.

Native of China and Cochinchina in wet places. Loureiro ſent it to Europe from the latter in the year 1774.

* Willdenow and Loureiro.

Spike cylindrical, culm aſcending, leaves oblique, root bulboſe.

DESCRIPTIONS, *&c.*

1. Root perennial. Culms from one foot to two or three feet in height in moiſt meadows, but in dry ſoils much lower, upright, round, and ſmooth. Leaves lanceolate, pointed, rough on the upper ſurface and along the nerve: ſheath ſtreaked, ſmooth. Spike regularly cylindric, and blunt at the top, ſometimes five or ſix inches long, but uſually, in its wild ſtate, much ſhorter: at firſt ſight it bears ſome reſemblance to that of Fox-tail Graſs; but on examination it will be found very different in form, colour, &c. It is alſo rough, whereas that is ſmooth; and the two horns at the top of the truncate calyx, betray it immediately. The flowers are very cloſe ſet on the ſpike. Pedunclcs very ſhort, ſomewhat branched: pedicels ſcarcely perceptible, confluent at the baſe, two-flowered. Valves of the calyx with briſtle-bearing dots, three-nerved, compreſſed, cuſped; the keel fringed with white, ſpreading, flexuoſe briſtles, alternately longer and ſhorter, the upper ones forked. Outer valve of the corolla five-nerved, naked, ſharpiſh, crenulate. Nectaries ovate, acuminate, ſurrounding the germ at the baſe. Anthers firſt violet, then aſh-coloured [7].

This graſs varies much in ſize, and in the length of the ſpike: it has alſo a leafy ſpike, in common with many other Graſſes, occaſioned by the ſeeds germinating in wet weather without falling. Profeſſor John Martyn obſerved it in this ſtate, during the month of October, on the banks of the river Wandle near Wandſworth. A variety with a bulboſe root is ſet down for a diſtinct ſpecies. This ſwelling of the root is a very equivocal character among Graſſes, and Ph. pratenſe is much given to it; but Linneus's Ph. nodoſum may probably be a diſtinct ſpecies.

Johnſon, in his edition of Gerarde's Herbal, ſays that it may be found with a bulbous root, by the bridge entering into Chelſey field, as one goeth from S. James to little Chelſey.

Meadow Cat's-tail Graſs was much recommended about thirty years ago, under the name of *Timothy Graſs*: and Mr. Wych is ſaid to have brought it from Virginia in 1763. It received this quaint appellation from Mr. Timothy Hanſon, who is ſaid firſt to have brought the ſeeds of it from New York to Carolina. It had then a great character in North America, where it is called *Herd Graſs*. Its reputation here was ſhort-lived, and it has no one good property in which it is not excelled by Fox-tail Graſs; but beſides this it is harſh, and late in its appearance. It is proper only for moiſt lands; in a dry ſoil it makes a pitiful appearance.

Some foreign writers ſpeak well of this graſs; Leers ſays it is very grateful to horſes—Krocker that both horſes and kine are fond of it green and in hay—Villars that it affords excellent forage. Our writers are of a different opinion: Dr. Pulteney ſays, that notwithſtanding the character which this graſs acquired from the recommendation of Rocque, ſheep diſlike it, and cows or horſes are not fond of it—Mr. Swayne, that it is a hard coarſe graſs, of little value for cattle—Mr. Curtis, that it is productive, but coarſe and late, and that it has no excellence which Fox-tail Graſs does not poſſeſs in an equal degree.

In moiſt grounds, kept down very cloſe by ſtock, it might however anſwer, with other coarſe Graſſes; ſuch as *Tall Oat* and *Orchard Graſs* (Dactylis glomerata.)

2. Root perennial, inclined to creeping, and a little tuberous. Stem moſtly ſolitary, ſimple, aſcending, a foot or more in height; leafy below; naked, ſmooth, ſtriated, and very ſtraight above. Leaves broadiſh, ſharp-pointed, rough in the margin. Stipules very ſhort, triangular and leſs abrupt than in the preceding. Sheaths of the upper leaves inflated, and longer than the leaves themſelves. Spikes ſcarcely an inch long, ovate or nearly cylindrical, obtuſe, tinged with dull purple, of which hue the ſtraw and ſheaths of the leaves moſtly partake. Glumes of the calyx ciliated with long hairs, and a little divaricated; keel green: the awns which terminate them being almoſt, if not quite as long as the glumes, diſtinguiſh this ſpecies from *pratenſe*, in which they are very ſhort. Corolla of two unequal valves, of which the largeſt is ribbed and bearded.

Native of the mountains of Lapland, Switzerland, &c. In Britain, it was firſt diſcovered near Garway Moor in Scotland; and probably may be found in ſimilar ſituations in other parts of our iſland, ſince it makes a principal part of the turf in the moſt elevated paſtures of Switzerland. It flowers with us at the end of july [8].

3. Root perennial, with an oblong bulb, tranſverſe and woody as it grows old, rooting deeply with blackiſh fibres ſpringing from the lower part of the tranſverſe tuber. Culm a foot high, ſimple, ſtraight, or procumbent at bottom, above almoſt naked. Root-leaves four or five, much narrower, and ſmooth. Stem-leaves about two, very ſhort, diſtant, with ſheaths much longer than the leaf, large, widened, the upper ſheath extremely ventricoſe. Spike in the flowering plant naked, and remote from the upper leaf, ovate, cloſe, villoſe. Florets ſeſſile: calycine valves equal, keeled, villoſe, manifeſtly ciliate at the ſides, whitiſh, variegated with green ſtains, having a ſhort awn at the tip. One valve of the corolla very wide, truncate, putting forth from the back a little longer awn than is curved inwards: the other linear, very narrow, and ſcarcely viſible. Filaments extremely ſlender. Piſtil roundiſh. This Graſs might be referred to *Alopecurus*, one valve of the corolla being ſcarcely diſcernible; the other convoluted and involving the genitals; but the truncate calyx determines it to be a ſpecies of *Phleum*, of which it has alſo the habit [9].

Native of the high mountains of Provence, Italy, Carniola, Styria, and of the Pyrenees.

4. According to Linneus this reſembles *Ph. pratenſe*; but the root is bulboſe; the culm not upright, but aſcending, and covered by the ſheaths of the leaves; which point in oppoſite directions, and are ſmooth, except at the edges, the ſpike is ſmooth, and the anthers are white.

Mr. Swayne remarks, that the lower joints of the culm ſwell into tubers, but the root is not bulboſe. According to Dr. Withering, there are three or four bulbs on the culm, half an inch aſunder; and two lanceolate ſcales to each bulbous joint; the culm is not only aſcending but knee-bent; and the leaves are narrower than in the common Cat's-tail Graſs.

Notwithſtanding we are told by Hudſon and Leers that this in a rich ſoil becomes *Ph. pratenſe*, I am not quite ſatisfied, ſays Dr. Withering, that theſe reſpectable authors may not have fallen into a miſtake from having conſidered variety γ of the firſt ſpecies as the Ph. nodoſum of Linneus: but that is a very common plant in England, whilſt the true Linnean *nodoſum* is rare.

The only ſpecimen I have ſeen of *Ph. nodoſum*, adds Dr. Withering, was ſent by the Rev. Mr. Swayne, author of the *Gramina paſcua*, a work extremely well calculated to ſpread a uſeful knowledge of the Graſſes amongſt the farmers, as well as to inſtruct the country gentlemen

[7] Leers.

[8] Engl. bot. [9] Gerard.

gentlemen in the beſt means of ameliorating our paſture lands. If my approbation could add any weight to ſo reſpectable a teſtimony to the uſefulneſs of Mr. Swayne's work, I ſhould be happy to give it. He found this Graſs, on the top of a wall about ſix miles from Bath, on the Warminſter road. I am doubtful whether ſome of the ſynonyms which I have given, belong to this, or to variety γ of *Phl. pratenſe*.

(Φλωμος *of Dioſcorides*, Linn. *In Ariſtotle* κλωμος, *in Suidas* φλωμος, *which is the ſame with* φλοιος, *from* φλεγω, *q.* φλογερ.—Φλωμις *and* φλωμιτις, *the ſame with* ουασις. *Dioſcor.* 3. 147. φλοιδις *ſcales*. Lexicon.) *Lin. gen. n.* 723. *Reich. n.* 781. *Schreb. n.* 978. *Tournef. t.* 82. *Juſſ.* 114. *Gærtn. t.* 66.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ* or *Labiatæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, oblong, five-cornered, toothed, permanent. *Involucre* below the whorl.

COR. one-petalled, ringent: *tube* oblong: *upper lip* ovate, vaulted, incumbent, compreſſed, villoſe, obſoletely bifid: *lower lip* trifid: the middle ſegment larger, two-lobed, blunt; the ſide ones ſmall, more acute.

STAM. *Filaments* four, concealed under the upper lip, of which two are longer. *Anthers* oblong.

PIST. *Germ* four-parted. *Style* the length and ſituation of the ſtamens. *Stigma* bifid, acute: the lower cleft longer.

PER. none. *Calyx* containing the ſeeds at the bottom.

SEEDS four, oblong, three-ſided.

OBS. *It differs from* Leonurus *by the want of points on the anthers.*

The figure of the calyx and lips of the corolla varies.

ESSENTIAL CHARACTER.

Cal. angular. *Cor.* upper lip incumbent, compreſſed, villoſe.

SPECIES.

1. Phlomis fruticoſa. *Shrubby Phlomis* or *Jeruſalem Sage*. *Lin. ſpec.* 818. *Reich.* 3. 69. *hort. cliff.* 315. *upſ.* 171. *Knipb. cent.* 1. *n.* 61. *Sabb. hort. rom.* 3. *t.* 15.

22. Phlomis biloba.
Deſfont. atlant. 2. 25. *t.* 127.
Leaves ovate-oblong tomenteſe, from four to ſix flowers in a whorl, calyxes half-five-cleft, villoſe-wool-bearing, upper lip of the corollas two-parted.]

DESCRIPTIONS, &c.

1. Mr. Miller makes three ſpecies of this. The firſt has a pretty thick ſhrubby ſtalk, covered with a looſe bark, riſing five or ſix feet in height, and dividing into many irregular branches, which are four-cornered and woolly when young, and afterwards become woody; their joints are pretty far aſunder; at each of theſe are placed two roundiſh leaves oppoſite, on ſhort foot-ſtalks; they are woolly on their under ſide. The flowers come out in thick whorls round the ſtalks, and are yellow; they appear from june to auguſt, but the ſeeds very rarely ripen here. It grows naturally in Spain and Sicily.

α. Narrow-leaved Shrubby Phlomis or Jeruſalem Sage does not riſe ſo high as the other; the branches are weaker; the leaves longer, narrower and rounder; the whorls of flowers ſmaller, but the flowers of the ſame ſhape and colour. Theſe have been long propagated in the Engliſh gardens. [Gerarde cultivated them in 1597. He calls them *French Sage* and Sage Mullein.]

β. This has a ſhrubby ſtalk like the former, but much lower, ſeldom riſing more than three feet and a half high, ſending out branches on every ſide. Leaves hoary, broader than either of the former, of an oblong ovate form, on pretty long foot-ſtalks and whiter. Whorls large, with bigger flowers, the upper lip of which is very hairy.

[Dillenius deſcribes the ſtems as from a foot to two feet in height, woody and upright; branches oppoſite, quadrangular, villoſe; leaves thick, at firſt hoary, but afterwards green on the upper ſurface; thoſe on the flowering branches are green on both ſides, on ſhorter and wider petioles, bluntly notched about the edge, but the notches ſcarcely viſible, eſpecially on the upper ones; the ſurface wrinkled and hirſute: the twigs on which the flowers grow are commonly curved in and reclined: whorls on each ſhoot two or ſometimes only one, terminating the uppermoſt branchlets, compoſed of ſeveral broadiſh, hirſute leaflets, and large flowers of a duſky yellow colour, in a wide head.

2. Stem rather ſhrubby, erect, branched, ſlightly quadrangular, covered with thick wool, eſpecially the younger branches. Leaves oppoſite, ovate-oblong, obtuſe, crenate, netted-veined, woolly on both ſides, but moſt on the under one; the lowermoſt cut off at the baſe, but not heart-ſhaped; on long foot-ſtalks; the upper ones on ſhorter. Foot-ſtalks channelled, very woolly: the wool of the whole plant is formed like little ſtars, as in various ſpecies of this genus and ſeveral others. Stipules none. Whorls ſeſſile in the axils of the upper leaves, conſiſting of ſix or eight flowers. Bractes ſeveral, as long as the calyx, ſomewhat imbricate, ending in a hard, ſharp point, rigid, concave, three-nerved, externally woolly, but ſmooth on the inſide. Flowers ſeſſile, the ſame ſize with thoſe of *P. fruticoſa*, but pale purple. Calyx regular, a little ſwelling, five-cleft in the margin; ſegments ſharp-pointed, erect: externally woolly, hairy at the angles and in the orifice. Corolla twice as long as the calyx: tube contracted in the middle: upper lip large, downy, hairy in the margin; lower lip nearly twice as long, hanging down, paler, veined, five-lobed; its outermoſt lobes acute, middle ones ſmall and obtuſe, odd one largeſt and notched at the tip. Seeds priſmatic, dotted at the top, brown.—This plant has a ſoapy ſmell, like the preceding.

This is the true *Ph. purpurea*, intended by Linneus, in the firſt edition of *Species Plantarum*, but confounded in the ſecond edition with another ſpecies, which is the next following.

Native of Spain. Barrelier found it in Valentia. Dr. Smith had it from the garden of John Coakley Lettſom, M. D. It flowers in june.

3. The leaves are leſs diſtinctly veined on the under ſide, in this ſpecies, than in the real *P. purpurea*, and almoſt equally woolly on both ſides, inſtead of being green on the upper; the lowermoſt are heart-ſhaped at the baſe. Bractes blunt, by no means pungent; half as long as the calyx, which is alſo remarkably obtuſe.

Native of Italy and Portugal. Common in our gardens[b]; and cultivated by Mr. Edward Morgan about 1661. It flowers from june to auguſt[c].

4. Root-leaves deeply cordate, oblong, bluntiſh: floral-leaves ovate. Calyxes hirſute. Involucres none[d].]

Root perennial, as are alſo the lower leaves, which do not ariſe from the root immediately, but ſtand in cluſters upon ſhort trailing woolly branches; they are placed without order on very long downy foot-ſtalks; are heart-ſhaped, downy on both ſides, four inches long, and two broad towards the baſe. Stalks annual, ſlender, a foot high. Leaves ovate-lanceolate, decreaſing in ſize to the top, where they are not half an inch long. Theſe ſtalks generally ſend out two ſide branches oppoſite, near the bottom, and from this diviſion to the top, have thin whorls of yellow flowers, not cloſely joined together, but each flower ſtands ſeparate. Calyxes ovate, very downy, and cloſely ſhut up. The flowers appear in june and july, but there are ſeldom any ſeeds produced in England. It grows naturally in the Archipelago, and alſo in Spain, from both which countries Mr. Miller received the ſeeds. [It was cultivated by him in 1759.

5. This has the habit of the firſt ſpecies, but the leaves are narrower; the corolla is ſcarcely bigger than the calyx. Involucres linear, erinite with long hairs[e].

Root hard, thick, twiſted. Leaves oblong, ruſſet-coloured, cottony. Flowers of a golden colour, handſome and very apparent[f]. Bractes cordate, acuminate. The dry leaves are uſed for wicks[g]; hence the trivial *Lychnitis*, and the Spaniſh *Candilera*.]

Root perennial. Root-leaves long, narrow, woolly, in tufts, inveloped at their baſe in a common covering, ſoft to the touch and procumbent. Stalks annual, ſlender,

[b] Smith. [c] Herb. kew. [d] Linn. ſpec. & ſyſt. [e] Linn. ſpec. [f] Villars. [g] D'Aſſo.

ſlender, near two feet long; their joints are far aſunder; at each of theſe is a pair of ovate leaves, embracing the ſtalk with their baſe. The whorls of flowers are alſo encompaſſed by theſe leaves, and within them is a radiated briſtly involucre, which covers the flowers. The lower leaves remain all the year.

Native of the South of France, Italy, Spain [and Portugal.—Cultivated in 1731, by Mr. Miller. It flowers from june to auguſt[b].]

6. Root perennial. Stalk a foot and half high, decays in the autumn, but the lower leaves continue all the year. Stem-leaves of the ſame ſhape with the lower, but ſmaller. Flowers in whorls: calyx downy: corolla of a duſky purple colour: they appear in june, but the ſeeds do not ripen here. It was diſcovered by Tournefort in the Levant, whence he ſent the ſeeds to the Royal garden at Paris. [It was cultivated in 1731, by Mr. Miller[c].

7. Stem upright, hirſute, four-cornered, herbaceous. Leaves very large, petioled, cordate, crenate, ſharpiſh; above greeniſh, with very ſhort, ſcarcely viſible villoſe hairs ſcattered about; beneath tomentoſe, hoary. Petioles hirſute. Whorls many-flowered, axillary and terminating. Braſtes (involucre) numerous, rigid, mucronate, pungent, pubeſcent, the length of the calyx; which is pubeſcent, coriaceous, five-cleft, ten ſtreaked, the ſtreaks alternately larger and ſmaller; ſegments awl-ſhaped, mucronate: corolla violet-coloured, of the ſame ſize and ſhape with that of *P. fruticoſa*, villoſe-tomentoſe[d].]

Root perennial. Root-leaves three inches long, and an inch and half broad at the baſe, ending in acute points; they are downy, and have five ſtrong veins on their under ſides. Stalks annual, a foot and half high: at each joint a pair of leaves of the ſame form, but ſmaller. Involucres cut into ſegments, and cloſely ſhut. This and the preceding, having been truſted to warm borders, were deſtroyed by the ſevere winter of 1740.

[It was diſcovered by Tournefort in the iſland of Samos; and Deſfontaines has ſince found it in Barbary. Mr. Miller cultivated it in 1743.]

8. Root perennial: when large it ſends up a great number of ſquare ſtalks, covered with a hairy down, and having ſeſſile leaves on them. Corolla bright purple.

[Root blackiſh. Leaves wide, crenate, duſky, and not very villoſe. Stems high and branched. Flowers red, duſky, and ſomewhat villoſe. A variety with yellow flowers is figured in Ruſſell's Aleppo, *t.* 16.

Native of the South of France; Miller adds Italy; Linneus, Perſia and Tartary. D'Aſſo found it in Arragon.—It was cultivated in 1683, by Sutherland; and flowers from july to ſeptember[e].

9. Root tuberous. Teeth of the calyx ſpreading, hiſpid. Helmet of the corolla toothed[f]. Seeds ovate-oblong, ſomewhat convex on one ſide, angular on the other, truncate above and hiſpid with white ſtar-like briſtles, acuminate below, ſmooth, ferruginous or deep cheſtnut colour: navel at the baſe of the ſeed ſimple[g].]

Stalks purple, four-cornered, five or ſix feet high. Leaves ſix inches long, three broad at the baſe, terminating in acute points, deeply crenate on their edges. Flowers of a pale purple colour and hairy: they appear in june and july, and the ſeeds ripen in ſeptember; ſoon after which the ſtalks decay; but the roots will abide many years.

[Native of Siberia. Cultivated in 1759 by Mr. Miller[h].

10. Stem of the ſame ſtature with *Ph. Leonurus*, two feet high, upright, herbaceous, four-cornered, blunt. Leaves ſubtomentoſe, marked with lines, petioled, remotely ſubſerrate, longer than the internodes. Whorls ſubterminating with an awl-ſhaped involucre. Calyx obliquely truncate downwards, obſcurely ſeven-toothed; the uppermoſt tooth longer. Corolla white: upper lip hirſute, very ſhort, vaulted, cloſed, entire, lower large, ſpreading, bifid; the intermediate ſegment wide, ſomewhat plaited; the middle ſcarcely three-lobed. Anthers black; compreſſed, truncate. One ſtigma ſeſſile above the ſtyle behind the tip; another lower, awl-ſhaped acute[i].

Native of the Eaſt Indies. Introduced in 1777, by John Gerard Koenig, M. D. It is a biennial plant; flowering from june to october[k].

11. Root branching. Stem four-cornered, more ſlender than a reed, ſoft and villoſe. Branches oppoſite, axillary, ſimple, almoſt erect, one longer than the other. Leaves ovate-lanceolate, bluntiſh, ſerrate, petioled, veined, ſoft and villoſe. Whorls at the leaves ſeſſile, roundiſh, many-flowered, denſe. Involucre and calyx hirſute. It is an annual plant, two feet high, upright, and without any ſcent[l].

Native of the Weſt Indies. Introduced in 1781, by Mr. Francis Maſſon. It flowers from july to ſeptember[m].

12. Stem herbaceous, upright, branched, villoſe when magnified, caneſcent. Leaves petioled, acute at the baſe, deeply and bluntly ſerrate, thin, villoſe when magnified, paler underneath, attenuated by a terminating ſerrature. Whorls many-flowered. Involucres the length of the calyx, keeled, hairy, ciliate, flexible, terminated by a whitiſh unarmed ſpinule. Flowers ſmall. Calyxes angular: with the three upper teeth ſmall, acute, almoſt equal, ſcarioſe at top. Helmet of the corolla extremely hirſute. It reſembles *Ph. indica*, but the ſtem and leaves are caneſcent with very minute hairs, and not tomentoſe; the leaves have deep ſerratures, flat not wrinkled and tomentoſe underneath, with ſmaller calyxes.

Found in the Eaſt Indies by Koenig, and in Arabia by Forſkahl[n].

13. Leaves ovate, ſerrate, attenuated at the baſe, petioled, clothed with ſoft hairs, green. Whorls towards the top two or three, thick, ſurrounded with erect, linear, keeled, villoſe involucres. Calyxes tubular, oblong, ten-cornered, at the exterior margin of the mouth produced into a three-toothed lip; at the back, where the margin is very ſhort, are two very minute teeth. Corolla like that of *Leonurus Cardiaca*: helmet very hirſute, with white hairs, longer, hoary: lower lip trifid; the middle ſegment twice as long as the two others. It is very nearly allied to *Ph. zeylanica*. Native of the Eaſt Indies[o].

14. This is a ſhrub with villoſe branches. Leaves petioled, bluntly ſerrate, quite entire at the baſe, pubeſcent above, villoſe underneath, very ſoft, green. Petiole very ſoftly villoſe, the length of the leaf. Whorls remote, fourteen-flowered. Involucres five or ſeven-parted, the ſame length with the tube of the calyx, villoſe. Calyx tubular, ten-grooved, villoſe, two-lipped: upper lip ſhort, oblong, acute; lower three-lobed, lateral lobes ſhort, the middle one four times as wide as the reſt, rounded, membranaceous, netted-veined. Corolla under the upper ſegment of the calyx and twice as long: tube the ſame width with the tube of the calyx and villoſe: helmet very hirſute at the margin: lower lip three-lobed, the length of the helmet. Filaments the length of the corolla.

15. Stem herbaceous, upright, acutely angular, the angles and joints reverſe-haired. Leaves petioled, ſpreading, bluntly ſerrate, quite entire at the baſe, ſomewhat hairy, acute. Whorls remote, ſix or eight-flowered. Involucres minute, four-parted, briſtle-ſhaped, ſomewhat pungent, ſmooth, yellowiſh at top, four times ſhorter than the calyx; which is ten-ſtreaked, ſmooth, nearly bell-ſhaped, oblique produced below into a three-toothed lip: teeth equal briſtle-ſhaped, ſeven-toothed at top. Corolla as in the preceding.

16. Stem herbaceous, ſmooth, bluntly angular: branches hairy at top. Leaves blunt, having three or four ſerratures in the middle on each ſide, hairy: petiole ſhorter than the leaf. Whorls remote, ten or twelve-flowered. Involucres four-cleft: ſegments briſtle-ſhaped, the length of the calyx: which is bell-ſhaped, pubeſcent: teeth awl-ſhaped, unarmed, the two upper ones larger. Corolla twice as long as the

calyx:

calyx: helmet very hirſute about the margin: lower lip three-lobed; the middle lobe produced, oblong.

Theſe three ſpecies were found in Arabia by Forſkahl.

17. Stem herbaceous, branched, ſlender, weak, ſlightly villoſe. Leaves petioled, bluntly ſerrate, (ſerratures four or five,) blunt, appearing thinly haired when examined by a magnifier, eſpecially at the ſides. Peduncles very ſhort, ſolitary, oppoſite, one-flowered. Bractes two, very ſmall, at the baſe of the calyx; which is ſtreaked and ten-toothed. Helmet of the corolla hairy, extremely hirſute on the margin.—Native of the Eaſt Indies [e].

18. Stem ſimple, upright, quadrangular, blunt. Leaves deeply and ſomewhat bluntly ſerrate, green. Petioles the length of the leaves. Whorls few towards the top, globular, many-flowered. Calyx ſomewhat hairy, cylindrical, with a ſpiny and very ſharp border, the upper tooth twice as large as the reſt, and from four to ſix ſmall teeth. Corolla villoſe, of the ſame appearance and colour with that of *Ph. Leonurus*, but one-third only of the ſize: upper lip roundiſh, long, emarginate; lower ſhort, trifid, even. Involucre awl-ſhaped, reflex. Filaments cohering in pairs. Stigmas two, filiform, the upper ſhorter by half than the under [f].

It is an annual plant, native of the Eaſt Indies; flowering here in ſeptember and october. Sir Joſeph Banks introduced it in 1778 [g].

19. This is a very handſome plant when it is in flower. Corolla of a tawny or golden colour and ſhining like ſilk: upper lip long, tomentoſe, ciliate, quite entire; lower lip ſhort, naked, membranaceous, the lateral ſegments reflex, dry, the intermediate one trifid, emarginate in the middle. Filaments ſnow-white. Anthers two-lobed, yellow, having globular meal ſprinkled over them at the baſe only [h].

It riſes with a ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral branches, which are four-cornered. Leaves about three inches long, and half an inch broad, hairy on their upper ſide, and veined on their under. The branches have each two or three ſeſſile whorls of flowers towards the ends. There is a variety of it with variegated leaves.

[Native of the Cape of Good Hope. Cultivated in 1712, in the botanic garden at Cheliea. It flowers from october to december [i].

20. It bears much reſemblance and is nearly allied to the preceding; but the leaves are ovate, not lanceolate, and more tomentoſe. It differs materially from *Leonurus*, by its awned calyxes. It agrees more with *Phlomis nepetifolia*, but differs from that in having a ſhrubby ſtalk; ſmall, blunt, more compact leaves; and the neck of the calyx rough-haired. The corollas agree in all the three ſpecies [k].]

Stalk ſhrubby, ſquare, three feet high. Branches four-cornered, in pairs. Leaves rough on their upper ſide, veined and pale green on their under. Corolla neither ſo long, nor ſo deep coloured as in the preceding.

Boerhaave and Miller frequently received the ſeeds from the Cape of Good Hope, where it grows naturally.—[It appears from the herbariums in the Britiſh Muſeum, that it was cultivated in 1713, by the Dutcheſs of Beaufort. It flowers in june and july [l].

21. Stem ſhrubby, with four-cornered hiſpid branches. Leaves ovate and ſubcordate, petioled. Whorls five or ſix-flowered, axillary; the flowers pedicelled. Calyx funnel-form, ten-ſtreaked, with ten awned teeth. Corolla white, with the upper lip compreſſed, hirſute on the outſide, eſpecially about the margin; lower three-lobed, almoſt naked.—Native of China [m].

22. Stems herbaceous, upright, branched, villoſe-woolly, with blunt corners. Lower leaves petioled; upper ſeſſile, ovate-oblong or ſometimes ovate, wrinkled, ſcarcely crenate, caneſcent, with branched and very ſhort villoſe hairs. Whorls diſtinct. Flowers ſeſſile or on very ſhort pedicels. Bractes linear filiform, the length of the calyx, covered with long cloſe caneſcent villoſe hairs. Calyx oblong, round; ſegments linear, acute. Corolla the ſize of that in the eighth ſpecies, purple, villoſe-tomentoſe on the outſide: upper lip bowed, compreſſed, often deeply two-parted; lower three-lobed, the two lateral lobes ſhort, ſmall, the middle one very large, ovate, blunt, grooved. It is a very beautiful ſpecies, and quite diſtinct from the reſt.—Native of the kingdom of Algiers [n].]

PROPAGATION AND CULTURE.

1. This was formerly kept in pots, and houſed in winter with other exotic plants; but of late years it has been planted in the open air, where it is ſeldom injured by cold, unleſs in very ſevere winters; ſo it is intermixed with other ſhrubs of the ſame growth in ſhrubberies, where it adds to the variety; for as theſe ſhrubs retain their hoary woolly leaves all the year, they make a good appearance in winter; and their yellow flowers, which continue great part of the ſummer, being intermixed with their hoary leaves, have a good effect.

Theſe ſhrubs ſhould have a dry ſoil and a warm ſheltered ſituation, otherwiſe they will not live in the open air. They may be planted among Ciſtuſes of all the different ſorts, the ſhrubby Moon-trefoil, ever-green Cytiſus, Wormwood-tree, and ſome other exotic ſhrubs of the ſame countries, which require a warm ſituation and a dry ſoil, being too tender for open plantations which are expoſed to ſtrong cold winds; and as they are not of long duration, they are better when ſeparated from trees and ſhrubs which continue many years; for theſe rarely live above twelve or fourteen years in dry ground, and not more than half ſo long in cold moiſt land, or where they are not well ſheltered.

They are propagated by cuttings, which if planted in a bed of light earth in april, juſt before the plants begin to ſhoot, and covered with mats to ſcreen them from the ſun every day, as alſo to obſerve when the ground is dry to give them water gently, they will get good roots in about two months or ten weeks, when they may be carefully taken up, and tranſplanted into a nurſery, where they may remain one year, and then be tranſplanted to the places where they are deſigned to ſtand, for theſe plants will not bear tranſplanting at a greater age.

2. 3. May be propagated and treated in the ſame way, only the latter is more impatient of cold: [indeed both are deſtroyed by ſevere froſt in the open border, and therefore muſt have ſome protection there occaſionally, or a plant may be kept in the green-houſe to guard againſt accidents.]

4. 5. May be propagated by ſlips in the ſpring. They require a dry ſoil and warm ſituation: [with the ſame care recommended for the two preceding ſorts in ſevere froſt.]

6. 7. Theſe are propagated by offsets from the root, which it ſends out very ſparingly; and very ſharp winters ſometimes kill the plants in open borders.

8. This may be increaſed by parting the roots in autumn, when the ſtalks begin to decay, that the plants may get root before the froſt comes on; but it ſhould not be parted oftener than every third or fourth year, if it be expected to have many flowers. It is hardy, and may be planted in expoſed places, but not in moiſt ground.

9. Sow the ſeeds upon an eaſt border in the ſpring; keep the plants clean from weeds, and in the autumn tranſplant them where they are to remain; the following ſummer they will produce flowers and ſeeds. This ſort is very hardy, and will thrive in almoſt any ſoil or ſituation.

[10 to 18. Being natives of hot countries, muſt be kept in the bark ſtove. Several of them are annuals, and can only be propagated by ſeeds procured from the countries where they grow.]

19. 20. Theſe are increaſed by cuttings planted in july; after the plants have been ſo long expoſed to the

[n] Deſfontaines.

open

open air as to harden the ſhoots, they will take root very freely. Plant them in a loamy border with an eaſtern aſpect, and if they are covered cloſely with a bell or hand glaſs to exclude the air, and are ſhaded from the ſun, it will forward their putting out roots; but when they begin to ſhoot, raiſe the glaſſes to prevent their drawing up weak, and by degrees expoſe them to the open air. As ſoon as they have taken good root take them up, and plant each in a ſeparate pot, filled with ſoft loamy earth, and placed in the ſhade, till the plants have taken new root; then remove them to a ſheltered ſituation, where they may remain till october, when they muſt be removed into the green-houſe, and afterwards treated as the Myrtle and other hardy green houſe plants; obſerving to water the 19th ſort plentifully.

All the ſpecies are ornamental plants, when properly diſpoſed in gardens and plantations; there is generally a ſucceſſion of flowers on them for two or three months, and their hoary leaves, interminxed with plants whoſe leaves are green, make a good contraſt.

DESCRIPTIONS, &c.

1. Stalk ſmooth, of a light green, about two feet high, ſending out a few ſide branches. Leaves near three inches long, and one broad in the middle, of a dark green and ſeſſile. Flowers in a terminating corymb, compoſed of many ſmaller bunches, which have each a diſtinct footſtalk, and ſupport a great number of flowers, which ſtand on ſhort ſlender pedicels. Calyx ſhort, cut almoſt to the bottom into five narrow acute ſegments. Corolla pale purple, appearing late in july, and often followed by ſeeds which ripen in autumn.

[It is a large, lofty plant. Stem obtuſe. Leaves broad-lanceolate; the margin roughened with very minute ſcattered prickles. Corymbs cluſtered into an umbel, with very numerous flowers, pubeſcent in the tube[f].

Native of North America. Cultivated in 1732, by James Sherard, M.D. It flowers in auguſt and ſeptember[g].

2. Flowers blue. Native of North America. Cultivated in 1759 by Mr. Miller. It flowers in july and auguſt[h].

3. Flowers white, moderately ſweet-ſcented. Native of North America. Introduced about 1766, by Peter Collinſon, Eſq. It flowers in july and auguſt[i].]

4. Stalks upright, of a purpliſh colour, cloſely covered with white ſpots, and about three feet high. Leaves about three inches long and one broad at their baſe, ending in acute points. Towards the upper part of the ſtalks are ſmall branches oppoſite, each terminated by a ſmall bunch of flowers; but on the top of the principal ſtalk is a long looſe ſpike of flowers, compoſed of ſmall bunches from the axils at each joint; each cluſter having one common peduncle near an inch long, but the pedicels are ſhort. The flowers are of a bright purple colour, and appear late in july; if the ſeaſon be temperate, or the ſoil moiſt, they will continue in beauty great part of auguſt, but rarely perfect ſeeds in England.

[Stem a foot high, round, ſomewhat rugged, purple with green dots. Leaves rugged about the edge, ſpreading, ſeſſile, alternate except the loweſt, which are oppoſite. Raceme terminating, with alternate peduncled corymbs, ſeparated by leaflets. Calyx five-cornered. Corolla violet[k]. Capſule ovate, with a diaphanous membranaceous calyx, marked with five green ribs, ſmooth: partitions growing to the axis, contrary to the valves, and ſeparating from them, but not from the axis, when ripe. Seed one in each cell, elliptic, plano-convex, with a raiſed ſtreak on the

[f] Linn. ſpec. [g] Hort. kew. [h] Idem. [i] Idem. [k] Linn. mant.

plane part, brown, the ſurface irregular as it were gnawn'.

Native of North America. Cultivated in 1759, by Mr. Miller. It flowers in auguſt [n].]

5. Stalks about a foot high. Leaves narrow lanceolate, ending in acute points, ſeſſile, a little hairy. Calyx cut into acute ſegments almoſt to the bottom. Tube of the corolla ſlender and pretty long, cut at top into five ovate ſpreading ſegments. Flowers light purple, appearing at the end of june, but ſeldom followed by ſeeds in England.—Native of North America. [Cultivated by Mr. Miller in 1759.

6. This reſembles the next ſpecies, but the ſtem is three times as high, and ſomewhat rugged. Leaves wider, and ovate-lanceolate. Corymb conſiſting of numerous flowers, with ſeveral pedunculs from the uppermoſt axils of the leaves, erect and faſtigiate into a ſort of corymb. Tube of the corolla even [o].]

Stems near two feet high. Leaves ſtiff, ſhining, ſeſſile, entire, with the edges reflexed. The upper part of the ſtem has generally two ſlender ſide branches, and is terminated by a head of flowers growing in whorls, but the whorls are ſo near, as to appear one corymb. Calyx ſhort, deeply cut into five acute ſegments. Tube of the corolla long, cut at top into five roundiſh ſpreading ſegments. The corolla is of a deeper purple than that of the next ſpecies, and the flowers appear a fortnight later. It grows naturally in Carolina; [was cultivated here before 1728; and flowers from july to ſeptember [p].]

7. Stalks near a foot and half high, dividing into three or four ſmall branches towards the top, each terminated by a corymb of flowers. Lower leaves oppoſite, three inches long, and near half an inch broad at the baſe, ending in long acute points, ſmooth and ſeſſile; the upper ones are alternate. Tube of the corolla twice the length of the calyx; ſegments of the border roundiſh, ſpreading, of a light purple colour. The flowers appear in june, but unleſs the ſeaſon proves warm are not ſucceeded by ſeeds in England.

[Native of North America. Cultivated in 1731, by Mr. Miller. It flowers from june to auguſt [q].

8. Stems almoſt upright, ſimple and then divided into two branches. Leaves oppoſite on a ſimple ſtem in five oppoſitions, ſoftiſh, rugged; the upper ones alternate. Flowers from the partings of the ſtem and the axils of the alternate leaves, two together on ſeparate pedicels. Calyx five-parted. Corollas pale blue, with a crooked tube [r].]

Stalks ſlender, and apt to incline to the ground if they are not ſupported; they divide into ſeveral ſmall ſpreading branches. The lower part of the ſtalks have broad-lanceolate leaves, alternate and ſeſſile: on the branches they are narrower and oppoſite. The flowers grow in looſe bunches at the ends of the branches: they have ſhort calyxes, cut into five narrow, acute ſegments; the tube of the corolla is long and ſlender; the ſegments are broad and obcordate, of a light blue colour. The flowers appear at the end of may or the beginning of june, but are rarely ſucceeded by ſeeds in England.

It grows naturally in North America; [and was cultivated in 1788, by Mr. Miller [s]. According to the Kew catalogue, it flowers from april to june. Mr. Curtis ſays it flowers in may, with the yellow Alyſſum; that it is neither of ſo long duration, nor ſo ornamental as ſome of the other ſpecies; that it ſeldom exceeds a foot in height, and on this account may be regarded as a ſuitable rock-plant.]

9. Stalks two or three, ſlender, about nine inches high. Leaves rough, hairy, an inch and half long, and three quarters of an inch broad in the middle, oppoſite, on very ſhort foot-ſtalks. The flowers come out ſingly at the top of the ſtalk, have very ſlender tubes, with a border of five roundiſh, ſpreading ſegments. They are of a light purple colour, and appear in july, but are not followed by ſeeds in England.

Native of Maryland, and other parts of North America. [Cultivated by Mr. Miller in 1759.

10. If this plant be left to itſelf, the ſtems trail on the ground, the young ſhoots are of a reddiſh hue, and ſlightly villoſe; the leaves are edged with hairs, oppoſite, recurved, and rather fleſhy, producing others from their axils, becoming as the plant grows old of a browniſh colour, which renders the plant in ſome degree unſightly. Flowers from one to three or four in an umbel, drooping before they expand: calyxes villoſe; corolla pale purple or fleſh colour, with an eye of dark but brilliant purple, diſpoſed in a ſtar-like form [t]: the lobes are emarginate, and the tube twice as long as the calyx.

Native of Virginia [u]. The flowers appear at the beginning of may; they are extremely pretty but delicate, requiring ſhelter during the period of their flowering, which is ſhorter than in moſt of the other ſpecies [x].

11. Lobes of the corolla rounded, entire. Calyxes of the ſame length with the tube of the corolla. Stems from two inches to a hand in height. Leaves linear, hairy below, ſucculent, bright green. From the uppermoſt axils pedunculs from two to four, about an inch long, hirſute, each bearing one purple flower (varying to white with purple ſtreaks), with from four to ſix ſegments, which are rounded and often emarginate.—Native of Siberia [y].

12. The ſtalks, when ſupported, riſe to the height of about a foot; but, if left to themſelves, trail upon the ground: they are thickly covered with leaves, which are longer, and for the moſt part finer and more hairy than thoſe of *ſubulata*; and in the month of may the whole plant forms a highly ornamental buſh of purple flowers. It was brought from Carolina, by Mr. John Fraſer, in 1788 [z].

All theſe beautiful plants are natives of North America, except the eleventh, which is indigenous of the north of Aſia. They are herbaceous perennials, and moſt of them tolerably hardy.]

PROPAGATION AND CULTURE.

Theſe plants delight in a moiſt rich ſoil, not too ſtiff, in which they will grow tall, and produce much larger bunches of flowers than in dry ground; for when the ſoil is poor and dry, they frequently die in ſummer, unleſs they are duly watered.

They are generally propagated by parting their roots, becauſe they do not often produce ſeeds in England. The beſt time for this is in autumn, when their ſtalks begin to decay. Theſe roots ſhould not be divided into ſmall heads, if they are expected to flower well the following ſummer; nor ſhould they be parted oftener than every other year, becauſe when they are often removed and parted, it will greatly weaken the roots, ſo that they will ſend out but few ſtalks, and thoſe will be ſo weak as not to riſe their uſual height, and the bunches of flowers will be much ſmaller.

When the roots are tranſplanted and parted, it will be a good way to lay ſome old tan, or other mulch, upon the ſurface of the ground about their roots, to prevent the froſt from penetrating the ground; for as they will have put out new fibres before winter, the froſt when it is ſevere often kills the fibres, whereby the plants ſuffer greatly, and are ſometimes deſtroyed.

The firſt, ſixth, and ſeventh ſorts, propagate pretty faſt by their ſpreading roots, but the others increaſe but ſlowly this way, therefore the beſt method to propagate them is by cuttings; and if theſe with the fourth ſort are deſired in plenty, they may be eaſily obtained by this method. The beſt time to plant the cuttings, is about the end of april or the beginning of may, when the ſhoots from the roots are about two inches high; theſe ſhould be cut off cloſe to the ground, and their tops ſhould be ſhortened; then they muſt be planted on a border of light loamy earth, and ſhaded from the ſun until they have taken root; or if they are planted pretty cloſe together, and covered with bell or hand-glaſſes, ſhading them every day from the ſun,

[n] Gærtner. [o] Hort. kew. [p] Linn. ſpec. [q] Hort. kew. [r] Idem. [s] Linn. ſpec. [t] Hort. kew. [u] Curtis. [x] Linn. ſpec. [y] Curtis. [z] Linn. ſpec. & Gmel. [a] Curtis.

they will put out roots in five or six weeks; but when they begin to ſhoot, the glaſſes ſhould be gradually raiſed to admit the free air to them, otherwiſe they will draw up weak and ſoon ſpoil: as ſoon as they are well rooted, the glaſſes ſhould be taken off, and the plants inured to the open air; then they ſhould be ſoon after removed into a bed of good ſoil, planting them about ſix inches diſtance every way, obſerving to ſhade them from the ſun, and water them duly till they have taken new root; after which, if they are kept clean from weeds, they will require no other care till autumn, when they ſhould be tranſplanted into the borders of the flower-garden, where they are deſigned to remain.

If ſome of theſe plants are put into pots, and ſheltered under a hot-bed frame in winter, they will flower ſtrong the following ſummer; and theſe may be placed in court-yards, or other places near the habitation, when they are in beauty, and being mixed with other flowers will be very ornamental.

[10. This ſort ſhould be frequently renewed by cuttings, which ſtrike readily. It may be ſuffered to grow either in its natural procumbent way, or be made to appear to more advantage by training it to a ſtick.

12. This ſpecies, like moſt of the others, is eaſily raiſed from cuttings, which ſhould be ſtruck early in the ſpring, to make them become flowering plants the next ſeaſon. To have this plant in perfection, it is neceſſary to renew it thus yearly, old plants being leſs productive of flowers, and leſs perfect in their foliage.

In mild winters, this ſpecies like many other plants from Carolina, will live abroad; but requires the ſhelter of a frame, rather than more tender treatment in ſevere froſt [r].

DESCRIPTIONS, *&c.*

1. This riſes to a great height in the warm countries; the ſtalks are generally full of rugged knots, which are the veſtiges of the decayed leaves, for the trunks of theſe trees are not ſolid like other trees, but the centre is filled with pith, round which is a tough bark full of ſtrong fibres while young, but as the trees grow old, this bark hardens and becomes woody; to this bark the leaves are cloſely joined, and in the centre riſe erect, being cloſely folded or plaited together, but after they are advanced above the ſheath which ſurrounds them, they expand very wide on every ſide the ſtem, and, as the older leaves decay, the ſtalk advances in height. The leaves of theſe trees, when grown to a ſize for bearing fruit, are ſix or eight feet long, and may be termed branches (for the trees have no other) theſe have narrow long leaves (or pinnæ) ſet on alternately their whole length. The ſmall leaves or lobes are towards the baſe three feet long, and little more than one inch broad; they are cloſely folded together when they firſt appear, and are wrapped round by brown fibres or threads, which fall off as the leaves advance, making way for them to expand; theſe never open flat, but are hollow like the keel of a boat, with a ſharp ridge on their back; they are very ſtiff, and, when young, of a bright green, ending with a ſharp black ſpine. Theſe trees have male flowers on different plants from thoſe which produce the fruit, and there is a neceſſity for ſome of the male trees to grow near the female trees to render them fruitful; or, at leaſt, to impregnate the germ, without which the ſtones, which are taken out of the fruit, will not grow. Moſt of the old authors, who have mentioned theſe trees, affirm, that unleſs the female or fruit-bearing Palm-trees have the aſſiſtance of the male, they are barren; therefore in ſuch places where there are no male trees near the female, the inhabitants cut off the bunches of male flowers when they are juſt opened, and carry them to the female trees, placing them on the branches near the female flowers to impregnate them; which, they all agree, has the deſired effect, rendering the trees fruitful, which would otherwiſe have been barren. Pere Labat in his account of America, mentions a ſingle tree of this kind, growing near a convent in the iſland of Martinico, which produced a great quantity of fruit, which came to maturity enough for eating; but, as there was no other tree of this kind in the iſland they were deſirous to propagate it, and accordingly planted great numbers of the ſtones for ſeveral years, but not one of them grew; therefore after having made ſeveral trials without ſucceſs, they were obliged to ſend to Africa, where theſe plants grew in plenty, for ſome of the fruit; the ſtones of which they planted, and raiſed many of the plants. He then conjectures, that the ſingle tree before-mentioned, might be probably ſo far impregnated by ſome neighbouring Palm-trees of other ſpecies, as to render it capable of ripening the fruit, but not ſufficient to make the ſeeds prolific.

The flowers of both ſexes come out in very long bunches from the trunk between the leaves, and are covered with a ſpatha, (or ſheath) which opens and withers; thoſe of the male have ſix ſhort ſtamina, with narrow four-cornered anthers filled with farina. The female flowers have no ſtamina, but have a roundiſh germ, which afterwards becomes an oval berry, with a thick pulp incloſing a hard oblong ſtone, with a deep furrow running longitudinally. The bunches of fruit are ſometimes very large.

[The fruit of this tree makes a great part of the diet of the inhabitants of Arabia and part of Perſia [a]. In Upper Egypt many families ſubſiſt almoſt entirely upon it. They make a conſerve of it with ſugar; and even grind the hard ſtones in their hand-mills for their camels. In Barbary they turn handſome beads for pater noſters of theſe ſtones [b]. The Date is ſaid to ſtrengthen the ſtomach and inteſtines, to ſtop looſeneſſes and promote expectoration, for which purpoſe it is given in pectoral decoctions. It is alſo recommended in the piles given in red wine [b].

[a] Ives. [b] Haſſelquiſt. [b] Long. jam. 742.

From

From the leaves of the tree they make baſkets or bags in Barbary. In Egypt they make fly-flaps of them, and bruſhes to clean their ſofas or cloaths. The hard boughs are uſed as fences to their gardens, and cages to carry their fowls to market. The trunk is ſplit for the ſame purpoſes, and is even uſed in ſmall buildings. It ſerves likewiſe for firing. The threads of the web-like integument between the boughs make ropes and the rigging of ſmaller veſſels[e].

The juice of the Date-tree is procured, by cutting off the head or crown of the more vigorous plant, and ſcooping the top of the trunk into the ſhape of a baſin; where the ſap, in aſcending lodges itſelf, at the rate of three or four quarts a day, during the firſt week or fortnight; after which the quantity daily diminiſhes, and at the end of ſix weeks or two months the tree becomes dry, and ſerves for timber or fire-wood. This liquor, which has a more luſcious ſweetneſs than honey, is of the conſiſtence of a thin ſyrup, but quickly becomes tart and ropy, acquiring an intoxicating quality, and giving, upon diſtillation an agreeable ſpirit or *Araky*, which is the general name for all hot liquors extracted by the Alembeck[d].

Native of the Levant, &c. Cultivated by Mr. Miller in 1731[e].

2. The little trunk this has is only about one, or at moſt two feet high, and ſo entirely enveloped in the leaves that it is never ſeen, the whole appearing like a large round buſh. Leaves pinnate, as in the preceding, and nearly as large: leaflets longer, narrower, more pointed, and of a much deeper green. Spathe axillary, one-valved; inſide concave, fitting the trunk or baſe of the leaf immediately within it: this concavity is bordered by two ſharp edges, outſide convex, there ſplitting longitudinally, leathery, ſmooth, withering. Spadix erect, much branched: branches ſimple, ſpreading in every direction; eight to twelve inches long. Filaments ſix, inſerted into a fleſhy globular receptacle: anthers oblong, erect. Petals in the female flowers orbicular, equal, rigid, calyx-like, laſting. Berry (or drupe) ſhining black, ſize of a large Kidney-bean; the pulp ſweet and mealy, but in ſmall quantity. Seed cartilaginous, of the ſame ſhape with the berry, grooved longitudinally, pretty ſmooth, brown on the outſide, light-grayiſh white within: on the middle of the back a ſmall elevation, under which is an oblong pit containing the embryo.

Native of Coromandel, in dry barren ground, chiefly on ſandy lands at a ſmall diſtance from the ſea. It flowers in january and february; and the fruit is ripe in may. This the natives eat as gathered from the buſh, without any preparation.

The leaflets are wrought into mats; the common petioles are ſplit into three or four, and uſed for making ordinary baſkets of various kinds; but they are not ſo proper for this purpoſe as the Bamboo.

The ſmall trunk, when diveſted of its leaves, and the ſtrong brown fibrous web that ſurrounds the trunk at their inſertions, is generally fifteen or eighteen inches long, and ſix in diameter, at the thickeſt part; its exterior or woody part conſiſts of white fibres matted together, which envelope a large quantity of a farinaceous ſubſtance, uſed as food by the natives in times of ſcarcity; but to ſeparate this from the fibres, the trunk is ſplit into ſix or eight pieces, then dried, beaten in wooden mortars, and afterwards ſifted: the reſt of the preparation conſiſts in boiling the meal into a thick gruel, or as it is called in India, congee. It ſeems to be much leſs nutritive than Sago, and is leſs palatable, being conſiderably bitter when boiled; but probably by more care in the preparation, or by varying the mode, it might be improved. It certainly deſerves attention, for during the end of 1790, and beginning of 1791, it ſaved many lives, Rice being very dear, and at times not to be had[f].

Loureiro has a dwarf Phoenix or Date Palm, which he names *Ph. puſilla*, and characterizes by its having ſix ſtamens, and a dwarf trunk. He deſcribes the trunk as two feet high, thick and rugged. Fronds ſix feet long, unarmed, pinnate, reclined: leaflets long, awl-ſhaped, plaited, ſmooth. Univerſal ſpathe many-valved. Spadix upright, ſhort, corymbed. Calyx of both flowers three-parted and very ſhort. Petals three, ovate-oblong, curved, ſpreading. Filaments, in the male flowers none, but ſix oblong anthers, equal to the corolla. Style in the female flowers ſhort, with a ſimple ſtigma. Drupe ovate, four lines in length, fleſhy, black, ſmooth, ſweet, with a ſingle, oblong, ſolid, horny nucleus, having a longitudinal groove on one ſide, and a ſmall circle on the other.

Native of Cochinchina, on mountains ſix leagues from Hüeá the capital of Cochinchina, in rocky places near ſtreams[g].

Loureiro refers to *Burm. zeyl.* 183. *Herm. parad.* 361. and *Kæmpf. amoen.* 667.

It ſeems in moſt reſpects not to differ from that deſcribed above from Coromandel.]

PROPAGATION AND CULTURE.

Theſe plants may be eaſily produced from the ſeeds taken out of the fruit, (provided they are freſh) ſown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanner's-bark, which ſhould be kept in a moderate temperature of heat, and the earth frequently refreſhed with water.

When the plants are come up, they ſhould be each planted into a ſeparate ſmall pot filled with the ſame light rich earth, and plunged into a hot-bed again, obſerving to refreſh them with water, as alſo to let them have air in proportion to the warmth of the ſeaſon, and the bed in which they are placed. During the ſummer they ſhould remain in the ſame hot-bed, but in the beginning of auguſt let them have a great ſhare of air to harden them againſt the approach of winter; for if they are too much forced, they will be ſo tender as not to be preſerved through the winter without much difficulty, eſpecially if you have not the conveniency of a bark-ſtove to keep them in.

The beginning of october remove the plants into the ſtove, placing them where they may have a moderate ſhare of heat (theſe being ſomewhat tenderer, while young, than after they have acquired ſome ſtrength; though indeed they may be ſometimes preſerved alive in a cooler ſituation, yet their progreſs would be ſo much retarded, as not to recover their vigour the ſucceeding ſummer. Nor is it worth the trouble of raiſing theſe plants from ſeeds, where a perſon has not the conveniency of a ſtove to forward their growth; for where this is wanting, they will not grow to any tolerable ſize in twenty years.

Whenever theſe plants are removed, (which ſhould be done once a year) be very careful not to cut or injure their large roots, which is very hurtful to them; but clear off all the ſmall fibres which are inclinable to mouldineſs, for if theſe are left on, they will in time decay, and hinder the freſh fibres from coming out, which will greatly retard the growth of the plants.

The ſoil in which theſe plants ſhould be placed, muſt be compoſed in the following manner, viz. half of light freſh earth taken from a paſture ground, the other half ſea-ſand, and rotten dung or tanner's bark in equal proportion; theſe ſhould be carefully mixed, and laid in a heap three or four months at leaſt before it is uſed, but ſhould be often turned over to prevent the growth of weeds and to ſweeten the earth.

You ſhould alſo obſerve to allow them pots proportionable to the ſizes of the plants; but you muſt never let them be too large, which is of worſe conſequence than if they are too ſmall: During the ſummer ſeaſon they ſhould be frequently refreſhed with water, but you muſt be careful not to give it in too great quantities; and in winter they muſt be now and then refreſhed, eſpecially if they are placed in a warm ſtove, otherwiſe they will require very little water at that ſeaſon.

Theſe plants are very ſlow growers, even in their native countries, notwithſtanding they arrive to a great magnitude; for it has been often obſerved by ſeveral of the old inhabitants of thoſe countries, that the

[a] Haſſelquiſt. [b] Shaw, 142. [c] Roxburgh. [d] Hort. kew. [e] Loureiro.

plants of ſome of theſe kinds have not advanced two feet in height in ten years; ſo that when they are brought into theſe countries, it cannot be expected they ſhould advance very faſt, eſpecially where there is not due care taken to preſerve them warm in winter. But however ſlow of growth theſe plants are in their native countries, yet they may be with us greatly forwarded, by placing the pots in a hot-bed of tanner's bark, which ſhould be renewed as often as is neceſſary, and the plants always preſerved therein both winter and ſummer, obſerving to ſhift them into larger pots as they advance in growth, as alſo to ſupply them with water properly, with which management I have had ſeveral of them come on very faſt; for I obſerve the roots of theſe plants are very apt to root into the bark, if their pots remain a conſiderable time without ſhifting, where they meet with a general warmth, and the moiſture ariſing from the fermentation of the bark preſerves their fibres plump and vigorous; but although the leaves grow tall in a few years with this management, yet it is long before the plants come to have any ſtems. There are plants in the Chelſea garden, whoſe leaves are ſeven feet long, which were raiſed from ſeeds more than twenty years ago, and their ſtems are not two feet high, ſome of which have produced ſmall bunches of male flowers.

PHOENIX. See *Andropogon* and *Poa*.

PHORMIUM. (Φορμιον *is the name of a plant in Ariſtotle's hiſtory of animals, of which they made mats. Forſter has given this name to a plant of New Zealand, uſed for the like purpoſe.*)

Chlamidia tenaciſſima. *Gærtn. fruct.* 1. 71.

DESCRIPTION, *&c.*

Leaves many. Inflorescence branched. Flowers of the Hyacinth. Capſule ſuperior, twiſted, attenuated outwards; valves bearing the partition in the middle; on the outſide of a ſmoaky or blackiſh colour, very finely ſtriated; within poliſhed, ſhining, pale bay colour. Seeds bracted, ſurrounded by a membranaceous margin, wrinkled, dark, ſhining, incumbent, faſtened in a double row to the inner margin of the partitions [b].

Native of New Zealand, Norfolk iſland, and other iſlands in the Southern ocean.

The inhabitants of New Zealand make a thread of the leaves, with which the women weave a variety of fine matting for cloathing and other uſes. Many other plants of the Liliaceous tribe might be applied to the ſame purpoſes [i]. It is now manufactured in Norfolk iſland: canvas and other coarſe linen cloth having been wove with the thread [k].

Lin. ſyſt. 548. *Suppl.* 277.

Calyxes finally opening longitudinally.

DESCRIPTIONS, *&c.*

1. Stem a foot high, obtuſely quadrangular, ſmoothiſh, brachiate. Leaves oppoſite, acute, ſomewhat rugged, groſsly ſerrate. Spikes terminating, ſolitary. Flowers oppoſite, remote. Bractes by threes, awl ſhaped: the lower of the ſame length with the calyx; the lateral ones erect, ſhort. Flowers horizontal, as they fade immediately drooping. Calyx cylindrical, striated, hard: upper lip purple on the outſide. Corolla white, the form of *Dodartia*, but ſmall [l]. Allied to *Verbena* [m].

The calyx, which is cloſed, bent down, pyramidal-awl-ſhaped, five-grooved and unequally five-toothed, ſerves for a pericarp: three briſtle-ſhaped recurved teeth, and two others that are membranaceous and ſtraight ſhut up the mouth. There is but one ſeed, and that of a brown-bay colour [n].—Native of North America.

2. Stems ſuffruticoſe at the baſe: branches oppoſite, few, upright. Leaves oppoſite, ſubpetioled, wedge-ſhaped, rounded above, equal in length and breadth, nine-toothed, thickiſh. Racemes terminating, ſolitary, quite ſimple, upright, with very ſhort pedicels. Bractes minute, awl-ſhaped, ſolitary. Calyx five-grooved, truncate, five-toothed. Corolla like that of Vervain: border five-cleft, ſmall, almoſt equal; with rounded ſegments. Seed filling up the calyx and burſting it, compreſſed a little, ſubcylindric, compreſſed-wedge-ſhaped at the baſe, two-celled. The calyx and corolla are regular in this; and as the fruit ripens, the calyx burſts longitudinally, expoſing the ſeed naked, almoſt as in *Lythrum Cuphea*. This plant is aſſociated with the preceding, till it is better known; though it has a different appearance. Thunberg found it at the Cape of Good Hope [o].

Nâru-kila. *Rheed. mal.* 11. 67. *t.* 34. *Raii ſuppl.* 573.

DESCRIPTION, *&c.*

Perennial, ſtemleſs, five feet high; on four fifths of it are very ſtraight, round, regular ſhining petioles. Leaves a foot long, ovate-oblong, ſharp, quite entire, flat, obliquely grooved, ſmooth, coriaceous. Flowers white, collected into a large, ſeſſile, hemiſpherical cyme, burſting out below the middle of the gaping petiole, (from which circumſtance Loureiro named it *Phyllodes*.) Involucre two-leaved, collecting together partial, many-flowered ſpathes. The root tubercled with fibres, horizontal, creeping. The germ is commonly abortive [a].

Native of Malabar, China and Cochinchina, in ſhady wet places.

It differs entirely from *Pontederia*, with which Linnæus aſſociated it; and approaches to *Thalia* ſo near that it may perhaps be a ſpecies of that genus [b]. According to Willdenow it is moſt nearly allied to *Maranta*, differing from it only in the ſeven-cleft border of the corolla, and the long channelled tube of the nectary.

The leaves are uſed for wrapping up cakes, &c. in the oven, whence Loureiro's trivial name of *placentaria*: when tender, and not yet unfolded, they infuſe them in ſpirit of rice or ſugar diluted with three times its quantity of water, to make vinegar [c].

Thunb. prodr. 44.
Leaves linear mucronate ſmooth, heads terminating birſute.]

DESCRIPTIONS, &c.

1. This is a low buſhy plant, ſeldom riſing more than three feet high; the ſtalks are ſhrubby and irregular, dividing into many ſpreading branches, ſubdividing into ſmaller ones. The young branches are cloſely beſet with ſhort, narrow, acute-pointed, ſeſſile leaves, of a dark green, and continuing all the year. At the end of every ſhoot, the flowers are produced in ſmall cluſters ſitting cloſe to the leaves; they are of a pure white, begin to appear in the autumn, continue in beauty all winter, and decay in ſpring. [Capſule ovate-globular, crowned with the permanent, white, villoſe, acutely-five-toothed calyx: ſkin membranaceous, ſlightly ſtriated, black; ſhells cartilaginous, thin, convex on one ſide, angular on the other, opening elaſtically by the inner angle. Seed one in each cell, faſtened to the bottom of it, of an oblong ſpheroidal form, ferruginous, ſhining, having a thick fungous white umbilicus at the baſe [a].]

It grows naturally at the Cape of Good Hope, whence it was firſt brought to the gardens in Holland: but it alſo occupies large tracts of ground about Liſbon, in the ſame manner as many lands in England are with heath.

[It was cultivated in 1731, by Mr. Miller [b]. The flowers are ſlightly odoriferous [c].

2. Found at the Cape of Good Hope by Thunberg.

3. Stem determinately branched: branches rod-like, ruſeſcent, white-pubeſcent. Leaves ſcattered, lanceolate-linear, like thoſe of the Yew-tree, revolute at the edge, ſpreading, ſubpubeſcent, white-tomentoſe underneath. Heads terminating, ſolitary. Common calyx ſhorter than the corolla, netted-veined, with lanceolate ſcales having a red keel, with hairs on the outſide the colour of red wine. The corolla has white hairs. The ſtigma is blunt [d].

4. This, as well as the preceding is a native of the Cape of Good Hope. If it be the ſame with the *pubeſcens* of the Kew catalogue, it was introduced by Maſſon in 1774; and flowers here from february to april.

5. This alſo is a native of the Cape, and was introduced at the ſame time by Maſſon. It flowers in november [e].]

6. This has an erect ſhrubby ſtalk, which riſes near three feet high, covered with a purpliſh bark, and here and there ſome white down upon it. Leaves narrow, ſhort, acute-pointed, ſeſſile, alternate on every ſide, thick, nerved, dark green on their upper ſurface, but hoary on their under. Flowers collected in ſmall heads at the end of the branches, white, woolly, fringed on their borders, cut into ſix acute ſegments at top. [Capſule ſubterminate, rounded-three-cornered, ferruginous, ſmooth, terminated at top by a widiſh area with three riſes, ſurrounded by a membranaceous, very narrow, toothleſs margin, from the fall of the calyx. Grains or diviſions of the capſules a little larger than in the firſt ſort. Seeds elliptic, deep cheſtnut-coloured, ſmooth but not ſhining: navel fungoſe, white, widely ſurrounding the baſe of the ſeed [f].

Cultivated by Mr. Miller in 1759. It flowers from march to may [g].

7. Native, as the reſt are, of the Cape of Good Hope. Found there by Thunberg.

8. Leaves compreſſed a little, rugged with minute dots, ſomewhat hirſute, ſpreading, ſubpetioled, with a tomentoſe groove underneath. Flowers ſolitary, ſeſſile, the ſize of a pea. Calyx with ciliate leaflets [h].

9. Stem proliferous, naked or ſomewhat rugged from the fallen leaves. Leaves ſcattered, awl-ſhaped, roundiſh, bluntiſh, even, ſpreading, channelled underneath or with revolute margins. Stipules in pairs, awl-ſhaped, very ſmall. Heads of flowers with a many-leaved calyx of naked, obovate, two-parted ſcales, interwoven with wool. Corollas funnel-form with a ſhort tube; ſegments of the border five, linear, long, woolly-white on the outſide. Stamens in the throat: ſtyle very ſhort, with three globular ſtigmas.—It differs from *P. ericoides*, by the horn-ſhaped ſegments of the corolla, longer than the yellow corolla itſelf [i].

Introduced from the Cape in 1786, by Maſſon [k].

10. Plant a fathom in height, with ſcattered branches, bifid or by threes at top, round elongated, ſmooth, purple, raceme panicled with flowering branchlets at top. Leaves ſeſſile, an inch and more in length, frequent, almoſt like thoſe of the Spruce Fir, blunt, even, quite entire, veinleſs, flexile, pale at the baſe. Inflorescence much reſembling that of *Ph. racemoſa*. Spikes from the upper axils, and the topmoſt twigs, ſometimes an inch and half in length, ſlender. Flowers ſeſſile, alternate, approximating, ſimple. Bracles linear, the lower ones longer than the flowers; alſo three ſcales, ovate, ferruginous, concave, blunt, ſhorter than the flower, at the baſe of each. Bottom of the corolla villoſe. Petals five, white, linear, blunt, without any nectary. Germ turbinate, ferruginous [l].

11. This differs from *Ph. buxifolia*, in having the leaves not ovate but cordate, drawn to a very fine point at the tip. The ſtem is proliferous, and the heads are not lateral [m].

12. Scales of the calyx rough with glaucous-gray hairs. Corolla with white hairs. It varies with revolute-linear leaves.—Found at the Cape by Burman [n].]

13. This riſes with a ſhrubby erect ſtalk five or ſix feet high, when old covered with a rough purpliſh bark, but the younger branches have a woolly down. Leaves thick, the ſize of thoſe of the Box-tree, veined, ſmooth and of a lucid green on their upper ſide, but hoary on their under; they have ſhort foot-ſtalks, and ſtand without order on the branches. The flowers are collected in ſmall heads at the ends of the branches; they are of an herbaceous colour and make no great appearance.

[It was cultivated in 1759, by Mr. Miller, and flowers during a great part of the year [o].

14. This differs from all the reſt by its inflorescence, or head of flowers elongated into a villoſe ſpike [p]. Introduced in 1774 by Maſſon. It flowers in november and december [q].

15. This is a very diſtinct ſpecies from *Ph. cordata*, with which it agrees in the form of the leaves [r]. Introduced with the preceding by Maſſon. It flowers in march and april [s].

16. This approaches to *Ph. calliſa*, but differs from it in not having the leaves rugged above, and the flowers racemed and panicled [t].

17. Found at the Cape by Thunberg.

18. Stem five feet high, ſhrubby, with determinate, ruſeſcent, ſubpubeſcent branches. Leaves alternate, cluſtered, ſeſſile, acute, quite entire, like thoſe of *Passerina macronata*. Panicle terminating, compoſed of ſpikes: flowers alternate, ſeſſile, ſimple, ſmall, within a cordate bracle. Calyx inferior, three-leaved, the length of the germ. Corolla ſuperior, five-parted: petals ovate, flat, even, white. Stamens the length of the

[a] Gærtner. [b] Hort. kew. [c] Linn. mant. [d] Idem. [e] Hort. kew. [f] Vahl. [g] Linn. ſpec. [h] Linn. mant. [i] Hort. kew. [k] Linn. ſuppl. [l] Hort. kew. [m] Linn. ſuppl. [n] Hort. kew. [o] Willdenow.

corolla. Germ turbinate between the calyx and corolla. Perhaps it may be of a diſtinct genus [a].

19. This ſhrub grows to the height of two feet, and is very like the firſt ſpecies; but the branches are many-flowered, and the flowers ſmaller [b].

20. Found by Thunberg at the Cape of Good Hope, where all the other ſpecies are natives.]

PROPAGATION AND CULTURE.

As theſe ſhrubs do not produce ſeeds in England, they are propagated by cuttings. There are two ſeaſons for planting theſe; the end of march, before the plants begin to ſhoot, and the beginning of auguſt. In the firſt ſeaſon plant them in pots, and plunge them into a very moderate hot-bed, covering them cloſe with bell or hand-glaſſes, ſhading them in the middle of the day, and refreſhing them gently with water: they will put out roots in two months; then inure them to the open air, and when they have obtained ſtrength, take them careſully out of thoſe pots, and plant each in a ſeparate ſmall pot, filled with ſoft loamy earth, placing them in a ſhady ſituation until they have taken new root; when they may be removed to a more ſheltered place, there to remain to autumn.

In the ſecond ſeaſon, plant the cuttings in pots, which may be either plunged into an old hot-bed or in the ground, covering them cloſe as before, and treating them in the ſame way: when they put out roots it will be too late to tranſplant them, and they muſt remain in the ſame pots until ſpring. If theſe are placed under a hot-bed frame in autumn, where they may be protected from froſt, and expoſed to the open air in mild weather, they will ſucceed better than when they are more tenderly treated.

Theſe ſhrubs being too tender to thrive in the open air in England, muſt be kept in pots, and houſed in winter: but they require no artificial heat. In ſummer they may be placed abroad in a ſheltered ſituation. As they flower in winter, they make a good appearance in the green-houſe or dry ſtove at that ſeaſon. The firſt ſort will live through the winter, when mild, in a warm ſheltered ſituation, but is always deſtroyed by ſevere froſt.

FEM. *Stigma* four-cornered. *Caſſ.* inferior, many-ſeeded.

SPECIES.

1. Phyllachne uliginoſa.

Forſt. gen. 116. *Lin. ſuppl.* 412.

DESCRIPTION, *&c.*

It is a very ſmall moſſy plant, growing in tufts, like the common Polytrichum. Stems cloſely approximating, covered with imbricate leaves, proliferous into two or three branchlets. Leaves ſmall, awl-ſhaped, crenulate with a cartilaginous margin. Flowers terminating, ſeſſile, white. It is a pretty plant, having the ſtructure of a Moſs all over, but adorned with flowers of a very different kind.

Native of Terra del Fuego, where it was found by Sparrmann [a].

Commerſon, who named it *Stibas*, deſcribes the corolla as being ſometimes ſix or ſeven-cleft, and the flowers as monoecous, with a ſingle ſtamen on one ſide, and a ſingle piſtil on the other [b].]

DESCRIPTIONS, *&c.*

1. Native of America.

2. Branches ſlender, covered with a light-coloured reddiſh-brown ſmooth bark, divided into twigs ſet with leaves at one-third of an inch diſtance from each other, two inches long and one inch and a half broad, with one middle and ſeveral tranſverſe ribs of a purple colour; petioles ten inches long[a].—Native of Jamaica.

3. Native of Antigua.

4. Native of the Weſt Indies.

5. Root filiform, long, white. Stem about a foot high, branched, erect, roundiſh, even. Leaves alternate, diſtant, often only terminating. Petioles filiform, bearing both leaves and flowers. Pinnas from eight to twelve pairs, alternate, oblong, entire, ſmall, ſmooth. Petiolets very ſhort. Stipules very minute, in pairs, at the baſe of the pinnas, coloured. Flowers on very ſhort peduncles, axillary, nodding, under the leaves. Males and females mixed, but ſolitary. Calyxes of both five-leaved; leaflets ovate, in the males pale. Theſe have one, columnar, round filament, and three twin contiguous anthers, with five glands at the baſe of the filament. Capſule ſix-valved, marked with three lines. Seeds ſix, oblong, angular[b].]

According to Miller, it is an annual plant, with an herbaceous ſtalk a foot and half high. The leaflets contract every evening, turning their under ſide outwards. The flowers are produced on the under ſide of the leaves along the midrib, and turn downwards. It uſually flowers here from june to october. The ſeeds ripen in ſucceſſion, and are caſt out of the capſules, when ripe, with ſo much force, as to be thrown to a conſiderable diſtance. It is very common in Barbadoes, (in the mountainous ſwamps of Jamaica, on the banks of rivers in Hiſpaniola; in the Eaſt Indies[c], and Japan[d]. It was cultivated in 1692, in the Royal Garden at Hampton Court[e].

6. Stem herbaceous, annual, one foot high, manifold, diffuſed, ſubprocumbent, hiſpid. Leaves many-paired: leaflets ovate-lanceolate, hairy, browniſh-green, oppoſite. Flowers heaped, axillary, ſubſeſſile. Stamens three. Styles three, bifid. Capſule three-cornered, three-valved, three-grained. The whole herb is milky; the ſtem, leaves and calyx reddiſh[f]. The leaves are erect in this, not horizontal as in the preceding; the ſtem ſubpubeſcent, not ſmooth as in that[g].

It has the trivial name from its diuretic quality; and is a native of the Eaſt Indies, China about Canton, Cochinchina, and the eaſtern coaſt of Africa[h].

7. Stem half a foot high, quite ſimple, aſcending, angular, even. Leaves alternate: leaflets alternate, oval, blunt, mucronate, on very ſhort petiolets, ſomewhat fleſhy, even, veinleſs, twice as big as thoſe of *Ph. Niruri*. Stipules in threes; two of them ſemicordate, acuminate, in pairs, the third or middle one under the petiole, awl-ſhaped, running down into the angular ſtem. Stipules at the leaflets two, acute. Male flowers a few, from each axil of the leaves, pendulous, minute; on one-flowered, capillary pedicels. Perianth of ſix, ovate-ſubulate, equal leaflets; (according to Swartz, ſix-parted.) Filaments three, very ſhort, approximating, with the anthers ſomewhat oblong; (but Swartz obſerves, that there is only a ſingle filament, with three twin anthers, ſo united as to appear like one that is ſix-grooved, or diſcharging its pollen by ſix grooves. Female flower ſolitary, terminating the compound leaves or common peduncle, it is on a longer peduncle than the male, and ten times bigger than that, or the ſize of the flower of *Uva Urſi*, and therefore ſingular. Perianth as in the male. Nectary ovate, three times as large as the calyx, with the mouth gaſhed. Capſule ſix-valved, elaſtic, and containing ſix ſeeds.

It is an annual plant, native of Tranquebar, where it was found by Koenig[i]. *See after n.* 11.

8. This very much reſembles the other ſpecies, but the leaves are ſimply pinnate; the leaflets alternate, linear, acute, ſmaller at the tip, where the petiole terminates in a contracted little raceme.—Native of Ceylon. *Koenig*[i].]

9. This riſes in Malabar with a tree-like ſtem to the height of twelve or fourteen feet, but in England not more than half that height, ſending out from the ſide many patulous branches. The leaves have very narrow leaflets.

[According to Loureiro, the common height is eight feet, with diffuſed branches. Leaves alternately pinnate, with many oblong-ovate, quite entire, ſmooth leaflets. Berry ſmall, ſomewhat pear-ſhaped, fleſhy, ſubacid, eatable, three-celled, two-ſeeded. Calyx of both flowers ſomewhat wheel-ſhaped, ſix-cleft; ſegments blunt, thick. Filaments none: anthers three, placed on the angles of a three-cornered receptacle. Flowers ſcattered. Germ three-cornered. Style none. Stigmas three, bifid.

Swartz obſerves, that the filament, in the male flower, is very ſhort and columnar: the three anthers minute and coaleſcent.—*See after n.* 11.

Native of the Eaſt Indies, Cochinchina and China, in which latter country, as Loureiro remarks, the berry is juiceleſs.—It was cultivated by Mr. Miller in 1768[e].

10. Calyx of the female flower ſix-toothed, blunt; of the male five-toothed: theſe latter have five ſmall petals, and three ſtamens[k]. Capſule orbicular, depreſſed, contained at the baſe in a ſix-leaved calyx, a little wider than itſelf, having ſix very obſcure ſwellings, tricoccous. The cocculi are papery, not ſeparating from the epidermis, two-valved, opening with a ſpring. Receptacle central, filiform, ſhort. In each cell two ſeeds, which are three-ſided, dotted, ſerruginous[l].—Native of the Eaſt Indies.

11. Native of the Society iſlands[k].

Gærtner ſeparates *Ph. Emblica* from the other ſpecies, becauſe it has not only a drupaceous fruit, but an embryo that is not ſpiral. He names it *Emblica officinalis*, and deſcribes the fruit to be a drupaceous capſule, globular, depreſſed, ſix-grooved, tricoccous; with a leathery-fleſhy, thick, ſmoothiſh rind. Shell ſtony, obovate, hexangular, mucronate at the tip, compoſed of three bony cocculi, having on one ſide a raiſed dorſal ridge, commonly (but not always) creſted with bundles of woody fibres; on the other they are angular; they are half-two-valved, and open with a ſpring from the baſe. Receptacle central, columnar, three-ſided. Seeds in each cell two, three-ſided, bowed on

[a] Sloane. [b] Swartz. [c] Idem. [d] Thunberg. [e] Hort. kew. [f] Loureiro. [g] Linn. [h] Loureiro. [i] Linn. mant. [k] Linn. ſuppl. [l] Hort. kew. [m] Reichard from Forſk. ægypt. 6. 159. [n] Gærtner. [o] Forſter.

one side, with flat planes on the other converging to an acute angle, smooth, bay-coloured, hard: navel simple, small, in the middle of the belly of the seed. Cover three-fold: outer membranaceous; middle cruftaceous, hard, brittle; inner membranaceous, ferruginous. Albumen fleshy, friable, pale. Embryo almoft the length of the albumen, inverted, milky: cotyledons leafy, cordate-lanceolate, with the edges reflexed towards the back of the feed and flightly bowed: radicle roundifh, fuperior.

Gærtner adds another fpecies, which he names *Emblica grandis*, and fufpects to be the *Ph. baccifermis* of Linneus. The fruit is a largifh globular drupe, very obfcurely three-grooved, fmooth, by age becoming brown or the colour of fmoke, tricoccous: rind thin, coriaceous. Cocculi bony, on the back very thick and convex, but on the fides thin and converging to an angle, two-valved. Receptacle obfcure below, but above three-forked; with roundifh arms, curved upwards, but running down in their proper grooves between the fides of the cocculi to the cruft of the rind, in which their fibres are ultimately difperfed. Seeds folitary, biggifh, thick, gibbous on one fide and as it were keeled on the back, flightly convex on the other, with a ftreak along the middle of the belly; in other parts fmooth, bay-coloured, perforated with a fmall hole under the tip: outer cover cruftaceous; inner membranaceous, with a wide ferruginous wart at the bafe: albumen thick, oily, whitifh: embryo inverted, fnow-white: cotyledons cordate-elliptic, leafy, flat: radicle fmall, fuperior. Retzius has three other fpecies from the Eaft Indies—*fimplex*, *ftellata*, and *rhamnoides*.]

PROPAGATION AND CULTURE.

Thefe plants may be propagated by feeds, when they can be procured from the countries where they grow naturally. They muft be fown on a hot-bed, and when the plants are fufficiently grown up, each fhould be planted in a fmall pot filled with light earth, and plunged into a hot-bed of tanner's bark; fhading and watering them until they have taken good root: after this, they muft remain conftantly in the bark-ftove, and be treated in the fame manner with plants from hot countries.

Stipules toothed.

DESCRIPTION, *&c.*

This plant rifes with a ſoft ſhrubby ſtalk about two or three feet high, which is ſeldom thicker than a man's finger, of an herbaceous colour, and full of joints. Theſe ſend out ſeveral ſmall ſide branches towards the top, garniſhed with ſpear-ſhaped leaves near four inches long, and almoſt two broad in the middle, drawing to a point at each end; they are of a lucid green on their upper ſide, but pale on their under, having a ſtrong whitiſh midrib, with ſeveral deep veins running from it to the ſides; the leaves are for the moſt part placed by threes round the branches, to which they fit cloſe. The flowers are produced at the end of the branches, in looſe panicles; they are ſmall, of an herbaceous colour at their firſt appearance, but before they fade, change to a brown or worn-out purple, and are cut into five parts to their baſe, where they are connected, and fall off without ſeparating. Theſe ſegments are reflexed ſo as to cover the germ, which is ſituated under the flower, and afterwards becomes a ſhort, turbinated, obtuſe, angular fruit, which ſplits in two parts when ripe, each containing one ſeed, flat on the inſide, convex on the outſide and angular.

[Gærtner calls the fruit a capſule. It is inferior, cruſtaceous, obovate, rhomb or lenticular-compreſſed, two-celled, bipartile: the cruſt on the back and ſides is coriaceous and thick, but on the belly membranaceous, ſubdiaphanous and white. Seed in each cell one, obovate, ſmooth, of a ruſty-red colour, convex on one ſide, flat on the other or very ſlightly concave; faſtened by the baſe. The ſeeds being of a different colour from the cruſt that covers them, entirely diſtinct and eaſily ſeparating from it; Gærtner, agrees with Adanſon in conſidering the ſeeds as included in a pericarp, rather than as being naked, with Linneus.

According to Fabricius, this plant recedes entirely from the *Umbellatæ*, in having an arboreſcent ſtem, ſimple leaves oppoſite or often by threes, and the flowers in a dichotomous panicle. The ſtructure of the germ and ſeed however ſhow it to be of that order [1].

Native of the Canary iſlands. Cultivated in 1699 by the Dutcheſs of Beaufort. It flowers in june and july [2].]

PROPAGATION AND CULTURE.

It is propagated by ſeeds, which muſt be ſown on a bed of freſh light earth towards the end of march, and the plants will come up by the beginning of may; when they are fit to tranſplant, they ſhould be put into ſeparate pots, and placed in a ſhady ſituation until they have taken root; after which time they ſhould be placed in a ſheltered ſituation, where they may have the morning ſun, and in the ſummer will require to be frequently watered. In winter they muſt be ſheltered from the froſt, but require to have as much free air as poſſible in mild weather; the ſecond year the plants will flower, if therefore in the ſpring ſome of the plants are ſhaken out of the pots and put into the full ground, they will perfect their ſeeds much better than thoſe which remain in the pots.

As theſe plants ſeldom continue in health above four or five years, it will be proper to raiſe a ſupply of young plants to ſucceed them.

The plants retain their leaves all the year, which being large and of a ſhining green, make a handſome appearance in winter, in which the beauty of it conſiſts, for the flowers have none.

DESCRIPTIONS, &c.

1. This riſes with a ſhrubby ſtalk near three feet high, dividing into ſeveral branches which grow erect, and are covered with a woolly down. Leaves ovate-lanceolate, almoſt three inches long, and an inch and a half

half broad in the middle, downy and on short petioles. Flowers small, of an herbaceous white colour, sitting very close to the branches; and succeeded by small berries nearly of the same size as the common Winter Cherry, and red when ripe.

[Branches flexuose, with short very close villose hairs. Leaves quite entire, the lower blunt, the upper sharp. Flowers glomerate, axillary, subsessile. Calyx pubescent, five-cornered, when the fruit is ripe ovate-pyramidal, five-toothed; teeth sharp. Corolla pale yellow, villose, twice as long as the calyx: tube very short: segments acute spreading [a]. According to Gærtner, the calyx has ten angles, the alternate angles standing out less. Berry spherical, scarlet, very shining, pulpy. Seeds biggish, dotted, pale yellow [b]. Fruit of Physalis, but flower of Atropa; herb of A. frutescens, which it resembles so much, that it can scarcely be separated from that genus [c].

Native of Spain, Sicily, Candia, Barbary, Zanguebar on the coast of Africa, and Mexico in America.

Cultivated in 1596 by Gerarde. It flowers in july and august.

2. Native of the Canary islands, where it was found by Masson. Introduced in 1779 [d].

3. Habit and stature of the first species; flowers in like manner scattered at the axils of the leaves; the calyxes also grow out and involve the berry: but it differs manifestly in having the flowers smaller, the branches very flexuose, and hence the leaves disposed as it were in a double row, inserted into the outer angles of the flexure.—Native of the East Indies [e].]

It rises to the height of five or six feet, sending out long flexuose branches covered with a gray bark. Leaves oblong-ovate, often placed opposite, sometimes by threes round the branches, to which they sit close. Flowers in clusters at the base of the petioles, small, of an herbaceous yellow colour: they are succeeded by round purplish berries having ten cells, each including one seed. It flowers in july and august, but unless the season is warm, the berries do not ripen in England.

4. Stalk shrubby, ten or twelve feet high, dividing towards the top into several small branches, covered with a gray hairy bark. Leaves on the lower part alternate; but towards the end of the branches opposite. Lower leaves from three to four inches long, and two broad in the middle, drawing to a point at both ends; they are of a pale green and are downy. Flowers from the axils towards the end of the branches, one, or two at the same joint opposite, on short nodding peduncles; they are small, of a pale dirty yellow colour, with purple bottoms. Berries small, spherical, red, included in an oval, dark-purple bladder.

It flowers in june and july, but unless the season proves warm, no berries succeed. Discovered by Dr. Houstoun at Campeachy, whence he sent the seeds to England. [It must therefore have been cultivated by Mr. Miller before 1733. Willdenow suggests that the *Ph. arborescens* of Thunberg is probably a different species.]

5. Root perennial, creeping. Stalks several, slender, about a foot high, becoming somewhat woody, but seldom lasting above two years. Leaves alternate, on short foot-stalks; they are about two inches long, and an inch and half broad. Flowers axillary towards the top, on short slender peduncles. Petals small, sulphur-coloured with dark-purple bottoms: they appear in july and august, but are rarely succeeded by berries in England.

Native of Curassao in the West Indies. [Cultivated in 1699, by Viscount Falkland [f].

6. Found at the Cape of Good Hope by Thunberg.]

7. Root creeping, sending up a great number of smooth stalks, about a foot high, dividing towards the top into small spreading branches. Leaves heart-shaped or ovate, about three inches long, and two broad near their base, entire, rough to the touch, of a pale yellowish green, alternate, on pretty long foot-stalks. Flowers towards the top, axillary, on long slender peduncles, of a dirty yellow colour with purple bottoms. They appear in june and july, and are succeeded by viscous berries about the size of the common sort, of an herbaceous yellow colour, inclosed in a light-green swelling bladder.

[Native of America. Cultivated in 1732 by James Sherard, M. D.]

8. Stems many, procumbent or erect, scarcely a foot in height, somewhat flexuose, roundish or obscurely angular, on the top at the flowers branched, having an obscure down scattered over them. Leaves alternate, like those of Boerhaavia, ovate, blunt, serrate-repand, almost naked above, obscurely tomentose underneath, next the flowers in pairs. Petioles shorter by half than the leaves. Peduncles at the axils of the branches, solitary, a little longer than the petioles. Calyx subcylindric, subangular, retuse at the base. Corolla yellow, darker at bottom. Stamens yellow. Berry globular, small, the size of a pea, red [g].]

Root not creeping. Stalks two feet long, spreading on the ground if not supported. Leaves three inches long, and two inches and a half broad, alternate on very long foot-stalks, pale green, having several acute indentures on their edges. Flowers axillary on very short peduncles, larger than those of the common sort, and of a pale yellow colour. They are succeeded by very small yellowish berries, which ripen in the autumn, when the season proves warm.

[Native of North America. Cultivated in 1726 by Mr. Miller. It flowers from july to september [h].]

9. Roots perennial, and creeping to a great distance. They shoot up many stalks in the spring a foot high or more. Leaves of various shapes, some angular and obtuse, others oblong and acute-pointed, of a dark green, on long foot-stalks. Flowers axillary, on slender peduncles, white, appearing in july. Berry round, the size of a small Cherry, inclosed in the inflated calyx which turns of a deep red in the autumn [succulent, very smooth, shining, red: skin membranaceous, very thin: pulp soft, red: partition very narrow, membranaceous. Receptacle central, solid, globular, fleshy, excavated, cohering with the inside of the berry by means of the partition. Seeds very numerous, covered with little raised points, yellowish or rufescent [i].

Native of the South of Europe, Germany, China, Cochinchina, &c.—Cultivated here in 1597 [k].

The berries of Alkekengi, commonly called with us Winter Cherries, were well known to the ancients, and are described by Dioscorides, under the name of Στρυχνὸς ἀλικακάβου. They have an acidulous and not unpleasant taste, followed by a slight bitterness, which they are said to derive from the investing calyx.

Though esteemed detergent and aperient, their fruit is chiefly recommended as a diuretic in suppression of urine, and for removing of obstructions occasioned by gravel or mucous. From six to twelve Cherries, or an ounce of the expressed juice, is given as a dose: there seems however to be no danger from a much larger quantity; for in some parts of Germany the country people eat them by handfuls, and in Spain and Switzerland, they frequently supply the place of other eatable fruits. Ray says, that a gouty person prevented the returns of the disorder, by taking eight of these berries at each change of the moon. Instances of their good effects are related in dropsical and calculous complaints, but at present they are wholly disregarded with us [l].

10. Plant very much resembling *Datura Metel*. Stem (in the stove) perennial, lofty, divaricating, very finely pubescent and extremely soft, as are also the leaves. Flowers solitary, pendulous, yellow, with five dusky spots at bottom, visible on both sides, and the throat hirsute.

Native of South America: found about Lima by Allstroemer [m]. Introduced about 1772. It flowers from april to october [n].—*Physalis peruviana* of Miller is *Atropa physaloides*.]

[a] Desfontaines. [b] Gærtner. [c] Linn. [d] Hort. kew. [e] Linn. spec. [f] Hort. kew.

[g] Gærtner. [h] Hort. kew. [i] Woodville. [k] Linn. spec. & syst. [l] Hort. kew.

11. This is ſeldom a foot high. Leaves of a deep green, on long foot-ſtalks. Flowers ſmall, white, on ſhort pedunculs. Berries ſmall, green when ripe.

[Stem ſtraight, the thickneſs of the little finger, three-cornered below, four-cornered above, as are alſo the branches, which come out obliquely from top to bottom, in alternate order, and are thicker at the baſe. Lower leaves wider and rounder than thoſe about the middle of the ſtem, and theſe larger than thoſe of the branches, deeply toothed or jagged, like thoſe of common Gooſe-foot, ſmooth. Flowers five-cornered, of an extremely pale yellow colour, with ſpots of a darker yellow at the baſe: ſtamens ſhort, purple, with oblong anthers of a duſky blue colour. Calyx of the fruit ſwelling, pendulous, oblong at firſt, but rounder afterwards, green frequently ſtreaked with dark purple at the angles, which are ſo little apparent in this ſpecies, that the bladder ſeems to be roundiſh. The fruit, when ripe, fills the bladder and burſts it.—The ſtem and leaves ſmell diſagreeably when handled [d].

Native of both Indies, Cochinchina and Japan. In the Eltham garden, where it was cultivated before 1732, it came up among earth that was brought with other plants from Carolina.

β. Dillenius has figured another Alkekengi which Linneus ſuppoſes to be a variety of the preceding, although the leaves are in a manner entire. Stem eighteen inches high and more, the thickneſs of the little finger at bottom, purpliſh green, ſmooth, three-ſided, but the upper branches four-ſided. Leaves reſembling thoſe of *Capſicum*, thin, ſmooth but not ſhining, the midrib whitiſh, paler underneath. Flowers ſmall, five-cornered, very pale yellow, with five duſky yellow ſpots at the bottom. In other reſpects this agrees with the preceding; as alſo in its diſagreeable ſcent. The only differences are, that the flowers and bladders are a little ſmaller, ſhorter and leſs produced, and the leaves always entire. The ſeeds of this were gathered by Dr. Sherard in Holland, and introduced into his garden at Eltham.]

12. This branches out very wide cloſe to the ground, and the branches frequently lie upon it; they are angular and full of joints, dividing again into ſmaller branches. Leaves on pretty long foot-ſtalks, about three inches long and almoſt two broad, having ſeveral acute indentures on their edges. Flowers produced on the ſide of the branches upon ſhort, ſlender, nodding pedunculs; they are of an herbaceous yellow colour with dark bottoms, and are ſucceeded by large, ſwelling bladders, of a light green, incloſing berries as large as common Cherries, which are yellowiſh when ripe. It flowers in july, and the berries ripen in autumn.

[Linneus remarks, that the ſpots on the corolla are duſky, not pale; the pedunculs nodding, not drooping; the berries globular, filling the calyx.

Native of America, eſpecially Virginia. Alſo of Cochinchina, according to Loureiro.—Cultivated in 1739, by Mr. Miller [e].

13. Stem herbaceous, branched from the bottom, brittle, a foot high. Branches and branchlets numerous, alternate, flexuoſe. Lower leaves oppoſite, ſtem-leaves alternate, branch-leaves in pairs one leſs than the other, petioled, ſpreading, cordate, the upper ones unequal at the baſe, bluntiſh, repand-ſubangular, villoſe underneath, brittle, bright green, flat, two inches long and upwards, and from eighteen to twenty-ones lines in breadth. Petioles rounded on one ſide, flattiſh on the other, channelled below, the length of the leaf. Flowers axillary, ſolitary or in pairs, pedunculed, fragrant, fugacious, an inch in width. Corollas violet, with a whitiſh eye, and radiating lines of a darker violet. Pedunculs round, villoſe; of the flower ſhort, upright; of the fruit lengthened, reflex, ſtill ſhorter than the petiole.

Native of Peru; found in the ſands near Lima by Dombey, who ſent the ſeeds to the Paris garden in 1780 [f]. It was introduced here in 1782, by Monſ. Thouin [g].

Monſ. L'Heritier remarks, that on account of its funnel-form corolla and diſtant ſtamens it might be referred to *Atropa*; but the bladdery calyx involving the berry determines it to this genus.

14. Stem ſlightly pubeſcent, pellucid, pale green tinged here and there with red, branchlets ſlightly channelled. Leaves cordate, with the lobes of the baſe placed ſpirally on each other, but little toothed. Calyx oblong, very long-pointed, pubeſcent; when in fruit conic-priſmatic, excavated-flat at the baſe. Corolla yellow with purple ſpots and anthers. Its purple anthers, unclammy leaves, want of hoarineſs, flowering pedunculs nodding and not very long, diſtinguiſh this from *Ph. pruinoſa* [h]. Retzius refers the *Alkekengi barbadenſe nanum* of Dillenius to this ſpecies. See *Ph. pruinoſa*.

According to Jacquin, the ſtem is round, about the thickneſs of a reed, villoſe, upright, with many divaricating branches. Leaves acute, toothed, ſoft, ſomewhat villoſe on both ſides, but not viſcid, on long petioles. Pedunculs ſhort. Flowers drooping. Corolla pale yellow, with five fulginous ſpots at the baſe. Fruits pendulous, deciduous. Fruiting calyx ovate, acuminate, ſmooth, veined, acutely five-cornered, aſh-coloured. Berry roundiſh, ſhining, very ſmooth, pale green, much leſs than the calyx, acid.—Native of Barbadoes.

15. This is ſufficiently diſtinct from the other ſpecies, by the berries being of the ſame ſize with the calyx [i].—See ſpecies 11 and 12. The native place is not known.

16. This is a ſmall ſpreading plant, with oblong hairs at the axils of the branches.—Native of the Eaſt Indies [k].]

Stems ſeldom above a foot high. Leaves ovate, of a deep green, on long foot-ſtalks. Flowers ſmall, white, on ſhort pedunculs. Berries ſmall, green when ripe.

[Native of the Eaſt Indies. Cultivated by Mr. Miller in 1759. It flowers in july and auguſt [l].

17. This has the appearance of the preceding ſpecies, n. 9. 10. 11. but the anthers are yellow, not blue; the branches round, flat above and villoſe; the leaves villoſe-viſcid; the axils of the ramifications germinant with a green ſort of froſting. Flowering pedunculs long, erect, ſtrict. Flowers drooping. Calyxes with a flat baſe. Berries ſubturbinate.

Native of America [m]. Mr. Miller cultivated it in 1726. It flowers in july and auguſt [n].

Forſter has another ſpecies, a native of the Society iſlands, which he names *Phyſalis flaccida*, but he does not give any deſcription or ſpecific character of it [o].

Mr. Miller has the following ſpecies not noticed by Linneus:]

1. Phyſalis virginiana.
Mill. dict. n. 4. fig. t. 206. f. 1.
Stem herbaceous, leaves ovate-lanceolate acutely toothed.

Root perennial, compoſed of ſtrong fibres, from which ariſe two or three hairy ſtalks nine or ten inches high, dividing into ſeveral branches. Leaves pale green and hairy, two inches and a half long, and an inch and half broad, placed alternately on ſhort foot-ſtalks. The flowers come out from the ſide of the branches, at the baſe of the petioles, which are long and ſlender. The corolla has a very ſhort tube, but is larger than in moſt of the ſpecies, ſulphur-coloured with a dark purple bottom. The flowers appear in july, and in warm ſeaſons are ſucceeded by oval yelloviſh berries, which ripen in the autumn. The ſeeds were ſent from Philadelphia by Dr. Benſil, who found the plant growing there naturally.

2. Phyſalis patula.
Mill. dict. n. 12.
Very much branched patulous, branches angular, ſmooth, leaves lanceolate pinnate-toothed.

This is a low annual plant. Leaves downy, with deep indentures on their edges, which are oppoſite, and regular like a pinnate leaf. Flowers ſmall and white. Fruit ſmall, yelloviſh when ripe.

[a] Dillenius. [b] Hort. kew. [c] L'Heritier. [d] Hort. kew. [e] Retzius. [f] Willdenow. [g] Linn. [h] Hort. kew. [i] Linn. [k] Hort. kew. [l] Flor. auſtral. n. 506.

3. Physalis villosa.
Mill. dict. n. 13.
Alkekengi americanum annuum ramosissimum villosum, fructu rotundo ex luteo virescente. *Houst. Mss.*
Very much branched, branches villose, leaves ovate acuminate serrate-toothed.
This is an annual plant, with a very branching hairy stalk. Flowers small, of a pale yellow colour. Fruit round, as large as a Cherry, and of a yellowish green when ripe.

4. Physalis cordata.
Mill. dict. n. 14.
Alkekengi americanum annuum, Lamii folio, fructu cordato. *Houst. Mss.*
Stem erect branched, leaves ovate serrate toothed, petioles and peduncles very long.
This is an annual plant, near two feet high. The leaves change to a purplish colour in the autumn. Flowers small and white. Berries almost as large as Heart-Cherries, and of that shape, yellowish green with some purple stripes.

5. Physalis maxima.
Mill. dict. n. 15.
Alkekengi americanum annuum maximum viscosum. *Houst. Mss.*
Stem erect branched, leaves ovate-lanceolate viscid, fruit very large heart-shaped.
This also is an annual plant, with a smooth stalk near three feet high. Leaves on long foot-stalks. Flowers small, pale yellow. Fruit pale yellow when ripe.
All these were found at Vera Cruz by Dr. Houstoun.

6. Physalis peruviana.
For which see *Atropa physaloides*.

PROPAGATION AND CULTURE.

1. Sow the seeds on a bed of light earth the beginning of april: when the plants are two or three inches high take them up carefully, and plant each in a small pot filled with kitchen-garden mould, placing them in the shade till they have taken new root; then remove them to a sheltered situation till the beginning of october; at which time remove them into the greenhouse, watering them sparingly in winter. They will continue several years, if they are not too tenderly treated.

3. Sow the seeds on a moderate hot-bed, and when the plants have four leaves, transplant them on a fresh hot-bed, shading them till they have taken new root; then admit fresh air to them every day in warm weather. When they are three or four inches high, take them up carefully, and plant each in a small pot, filled with light loamy earth, placing them in a frame upon an old hot-bed, and shading them till they have taken new root; then gradually inure them to the open air, into which they may be removed in july, and being placed in a warm situation, they may remain there till the end of september. The first winter place them in a moderate stove; but when they have obtained strength, they will live through the winter in a good greenhouse.

4. Sow the seeds in the same manner, and treat the plants as directed for the preceding; except that not being so hardy, they must be kept in a moderate stove in winter; but in the middle of summer they should be placed in the open air, in a sheltered situation, for about three months; for if they are constantly kept in the stove, they will draw up weak, and not flower. It may also be increased by cuttings, planted in pots during the spring and summer months, and plunged into a gentle hot-bed.

5. 7. Part the roots in the spring: place the plants under a hot-bed frame, or other moderate warmth in winter, and during the months of july, august and september, in a warm situation in the open air.

8. Sow the seeds upon a warm border at the end of march; when the plants come up, thin them where they are too close, and keep them clean from weeds till autumn, when they should be transplanted to the places where they are to remain, which should be in a warm situation, where they will live through the winter in mild seasons.

9. This sort is easily propagated, either by seeds or by parting the roots; the latter, being the most expeditious method, is generally practised, any time after the stalks decay, till they begin to shoot in the spring: it loves a shady situation, and should be confined, otherwise the roots will ramble to a great distance. Its only beauty is in autumn, when the fruit is ripe.

11, &c. The annual sorts are propagated by seeds sown on a moderate hot-bed, and when the plants come up and are a little advanced, they should be planted on a fresh hot-bed to bring them forward, and treated in the same way as the Capsicum. When they are grown strong, and are hardened to bear the open air, they may be transplanted with balls of earth to their roots into a warm border, observing to water and shade them till they have taken root, after which, they will require no other care but to keep them clean from weeds.

12. If the seeds are permitted to scatter, the plants will come up in the spring, and require no other care but to thin them, and keep them clean from weeds; or if the seeds be sown in the spring on a common border, the plants will rise very well, and need no other care.

Rapunculus creticus ſ. pyramidalis altera. *Bauh. pin.* 93.

R. creticus petromarula. *Bauh. hiſt.* 2. 811. *t.* 812.

Leaves pinnate, flowers in cymes.

DESCRIPTIONS, *&c.*

The European ſpecies of Phyteuma have the flowers in a cloſe terminating head or ſpike: thoſe from the Eaſt have them ſcattered: in all, there is a little bractle to each flower, as in Plantago.

1. This is a very ſmall perennial plant; the ſtem being only about two or three inches high. In habit it reſembles Ph. hemiſpherica, but the leaves are petioled, ovate-lanceolate, and notched here and there. There is probably much variety in this circumſtance; for Haller ſays they are ſerrate or bluntly toothed, and Villars that they are entire. Flowers in ſmall number, ſupported by floral leaves that are wider than the others, cordate and blunt, by which it is alſo diſtinguiſhed from Ph. hemiſpherica. Head ſingle, thin, having not more than twenty large, blue flowers: teeth of the calyx the length of the germ. Style often bifid. Capſule two-celled or three-celled [p].—Native of the South of Europe.

2. Root-leaves ſometimes elliptic and blunt, or obſoletely cordate. Allioni's figure is very good, but too large. Villars's plant is perhaps a variety with a more oblong ſpike [q]. He thus deſcribes it: Root perennial, deep, fuſiform. Stem ſtrong, channelled, ſtraight, about a foot high. Leaves ſmooth, oblong, very ſlightly and remotely toothed, reſembling thoſe of *Campanula perſicifolia*. Flowers blue, in a cloſe ſpike from half an inch to an inch in length, with lineat almoſt imperceptible bractes.—Native of the Swiſs and Piedmonteſe mountains.

3. Head roundiſh, but when out of flower becoming more oblong. Leaves rigid, linear, with ſometimes a tooth or two, eſpecially above.—On mont Cenis, and the mountains of the Valais and Tuſcany [r].

4. It reſembles the preceding, but differs in having the leaves longer, flaccid and more lanceolate [s]. Haller remarks that the ſtyle is trifid. Scheuchzer obſerved it on the Speluga with a white flower.—Native of the South of Europe.

5. Root biennial or perennial. Leaves wide, blunt, crenate, dark green. Bractes cordate [t]. The lower leaves are petioled, the upper half embracing [u]. It varies with all the leaves ſpatulate and blunt [v].—Native of monte Baldo, and the Tyroleſe and Carniolian mountains.

6. The long woody root branches near the ſurface into ſeveral diviſions, each bearing a denſe tuft of pe-

[p] Haller, Scop. Villars, Linn. [q] Willdenow. [r] Idem.
[s] Idem. [t] Villars. [u] Scopoli. [v] Willdenow.

tioled, ſmooth, veiny ſerrate or rather crenate leaves, the firſt of which are heart-ſhaped, the reſt ovate-lanceolate. Stem ſimple, about a foot high, erect, ſlightly angular, clothed with alternate lanceolate leaves, the uppermoſt very acute, and ſomewhat recurved. A ſingle round head of blue flowers ſtands erect, on a few ovate acute ciliate bractes. The parts of fructification agree in ſtructure with *Campanula*, except that the corolla is divided to the very baſe, into five linear ſpreading ſegments, which in the bud cohere together, forming a curved horn, and ſeparating firſt at their lower part. Every part of the flower remains permanent, though faded, till the ſeeds are diſperſed, or longer. The herb is milky, but not acrid [f].

Native of the South of Europe, and of England in Surry, Suſſex, and Hampſhire, on chalk downs; as about Leatherhead, on Epſom downs, on the South downs; found near Maple-Durham in Hampſhire by Merrett; near Sutton and Dorking by Blackſtone; on Beacon-hill near Feverſham, Kent; alſo between Kingſbury and Harrow, and between Harrow and Pinner in Middleſex; and between Selbury-hill and Beacon-hill in the way to Bath. It flowers in july and auguſt.

β. Stem higher. Leaves petioled, lanceolate, and leſs rough. The flowers have often two ſtigmas.

γ. Leaves elliptic, oblong, blunt, ſoft, almoſt ſmooth. Stem almoſt a foot high.

δ. This has the habit of Campanula rotundifolia. Roots thick, twiſted, branched and knobbed. Stems thin, channelled, three or four inches long. Lower leaves round, heart-ſhaped: ſtem-leaves narrower the higher they are, having ſome diſtinct hair on their borders. Bractes very thin, filiform, a little longer than the flowers, which form a ſpherical ſpike, and are blue [g].

Monſ. Villars has named it from Monſ. Charmeil, a ſurgeon, who uſed this plant with great ſucceſs in venereal complaints.

7. The flowering ſpike is ovate, but it is lengthened out as it advances to maturity. It is a native of Bohemia, and is very diſtinct from all the ſpecies in the dark violet colour of the flower, the briſtle-ſhaped bractes, and the ſhape of the leaves. Villars's figure of *Ph. cordifolia* reſembles this, except in the head and bractes [h].

8. Root-leaves oblong, obtuſe, crenate, a little villoſe, cordate: ſtem-leaves lanceolate, oblong. Spike of flowers twice as long as it is wide, with very ſhort bractes. Flowers ſmall, with two ſtigmas.—Native of Dauphiné [i].

9. Root yellow on the outſide, white within, having ſome ovate little tubers hanging to it at bottom. Stem upright, not branched, a foot and half high, angular, ſmooth. Root-leaves cordate-ovate, on ſmooth petioles, grooved above, an inch and half long, running down a little into the petioles; they are an inch and half in length, and almoſt an inch in breadth, having frequently a blackiſh mark in the middle, and ſmall roundiſh blunt toothlets about the edge: ſtem-leaves alternate, linear-lanceolate, the uppermoſt quite entire; all bright green, ſmooth. Spike cylindrical, cloſe, two inches long, and one inch wide. Flowers ſeſſile, with a lanceolate bracte to it. Corolla blue [k], varying to whitiſh yellow. Capſule inferior, membranaceous, very thin, crowned with the radiating teeth of the calyx, pyramidal-globular, deeply two-grooved, and having three or five acute-angled ribs on each lobe, two-celled, opening by a round lateral hole between the lobes. Receptacle oblong, fleſhy, tubercled, faſtened longitudinally to the partition on each ſide. Seeds very numerous, ſmall, ovate, ſomewhat angular, ſmooth, ſhining, ſubferruginous, darker coloured at top and bottom [l].

Native of Germany, Switzerland, Auſtria, France and Italy. The whole plant abounds with a milky juice. The root is eaten boiled. Bees are fond of the flowers [m]. Cultivated 1683, by Mr. James Sutherland [n].

[f] Engliſh Botany. [g] Villars. [h] Willdenow. [i] Villars. [k] Pollich. [l] Gærtner. [m] Krocker. [n] Hort. kew.

10. Stem from eighteen inches to two feet in height, not branched. Root-leaves on long petioles, acutely gaſhed, like thoſe of the Nettle. Lower ſtem-leaves heart-ſhaped, upper ones more ſlender, long-lanceolate. Spike thick, longer than in ſome of the others. Bractes long, linear-lanceolate, and frequently two very large ones under the ſpike. Flower deep violet. Capſule two-celled [o].—Native of Bohemia, Switzerland and Piedmont.

11. For the deſcription of this plant ſee Campanula virgata, n. 77.

12. The lower toothlets of the leaves are elongated. It reſembles the preceding very much, but differs in having the flowers peduncled, the ſtem panicled with the branches brachiate, not ſtrict and rod-like, and the flowers narrower.—Native of Armenia, where it was found by Tournefort.

13. From the baſe of the rugged ſtalk ariſe filiform branches leafy to the middle, covered at the top with geminate diſtant ſeſſile flowers. Corolla of the ſame ſize with the preceding.—Found in Armenia by Tournefort.

14. The leaves appear to be quite entire, but when examined by a magnifier they are found to have very ſmall, thin-ſpread, blunt teeth on the thickened margin. It reſembles the preceding very much, but the leaves are ſmoothiſh and more rigid, the ſtem ſimple, ſmooth, and the peduncles ſomewhat branched and three-flowered.

15. Stem round, ſmooth, ſimple, leafy. Leaves ſmooth. Flowers on the upper part of the ſtem, diſtant, peduncled. Peduncles five, ſupported by an ovate-lanceolate, ſharply ſerrate, ſeſſile bracte. Corolla of the ſame ſize and appearance with P. ſpicata. Theſe are both natives of the Levant, and were found by Tournefort.

16. Stem ſomewhat branched, ſmooth, grooved. Leaves unequally pinnate; the lateral leaflets oblong-lanceolate, oblique, toothed on the lower margin only; the terminating leaflet very large, roundiſh-ovate, gaſh-toothed. Flowers the largeſt of any of the ſpecies, in many-flowered, ſcattered, alternate cymes, diſpoſed on the upper naked part of the ſtem.

Native of the iſland of Candia or Crete [p].]

PROPAGATION AND CULTURE.

All the European ſorts are hardy plants, which will thrive in the open air. They are propagated by ſeeds which ſhould be ſown in autumn, for if they are kept out of the ground till the ſpring, they frequently fail, or at leaſt lie a year in the ground. Theſe ſeeds ſhould be ſown on a bed of freſh undunged earth where they are deſigned to remain, for they do not thrive ſo well when they are tranſplanted; therefore the beſt method is to make ſmall drills croſs the bed about eighteen inches aſunder, and ſow the ſeeds therein; then cover them lightly over with earth, for if they are buried too deep, they will rot in the ground. In the following ſpring the plants will come up, when they ſhould be diligently weeded, which is all the care they require; only they ſhould be thinned where they are too cloſe, ſo as to leave them ſix or ſeven inches apart in the rows, and afterwards they require no farther attention but to keep them clear from weeds. In june the plants will flower, and if the ſummer prove favourable, they will produce ripe ſeeds.

As theſe plants do not continue above two or three years, there ſhould be ſeeds ſown every other year to continue the ſorts. They are plants which require little trouble to cultivate them, and their flowers make a pretty variety in large gardens, therefore they may be allowed a place amongſt other hardy flowers.

Lin. spec. 632. *Reich.* 2. 407. *L'Herit. stirp. nov.* 145. *t.* 70. *Ait. kew.* 2. 123.
Flowers dioecous.

DESCRIPTIONS, *&c.*

[1. Root perennial. Stem two feet high, branched, upright, striated, smooth, hollow. Leaves scattered, petioled, lanceolate, quite entire, smooth, an inch and half in length. Flowers racemed, pedicelled, with some awl-shaped little bractes near and above the base. Corolla white, green underneath, spreading. Filaments the length of the petals, with roundish anthers. Pistils shorter by half. Berries fix in a calyx, distinct, yellow, pellucid, one-seeded. It is much smaller and more tender than the other sorts.—Native of America[1].

2. This has the stature of the common sort or *Ph. decandra:* but the leaves are whiter. The common peduncle is very short; and there are scarcely any pedicels. Calyx and corolla white, quite flat and not concave. Fruit red[2].

Native of Mexico. Cultivated in 1732, by James Sherard, M. D. It flowers from july to november[3].]

According to Mr. Miller Dr. Houstoun found it at Vera Cruz, where the inhabitants constantly used it at their tables. It seldom continues longer than two years, and when it flowers and seeds plentifully the first year, the plants frequently die before the following spring. The stalk is herbaceous, two feet high, about the size of a man's finger, and divides at top into two or three short branches. Leaves ovate-lanceolate, near six inches long, and almost three broad; they have a strong midrib, and several transverse veins, are of a deep green, and the foot-stalks are an inch and half long. The peduncles come out from the side of the branches opposite to the leaves, are seven or eight inches long, the lower part, about two inches in length, is naked; the remainder has sessile flowers, white with a blush of purple in the middle, cut into five segments almost to the bottom, and having from eight to fourteen stamens, and ten styles. Berries flat, with ten deep furrows; cells the same number, with one or two smooth seeds in each.

[Browne calls it Spanish Calaloe, and says it is a native of Jamaica, now cultivated in most of the kitchen gardens. It is a palatable wholesome green: the tender stalks are frequently served up for young Sperages (Asparagus,) and often prove a very agreeable succedaneum.

Thunberg on the contrary affirms that it is extremely poisonous; and relates, that having been eaten by two Japonese servants, one of them was eight days in recovering, and the other suffered during a much longer time.

Probably different species are confounded in these accounts.]

3. Root very thick and fleshy, as large as a man's leg, divided into several thick fleshy branches, which run deep in the ground. Stems three or four, herbaceous, as large as a good walking-stick, of a purple colour, six or seven feet high, dividing into many branches at the top. Leaves five inches long, and two inches and a half broad, rounded at their base, but terminating in a point, placed without order, on short foot-stalks; they are of a deep green, and in the autumn change to a purplish colour. The peduncles come out from the joints and divisions of the branches, and are about five inches long; the lower part is naked, but the upper half sustains a number of flowers ranged on each side like common Currants. Each flower stands upon a pedicel half an inch long, and the petals are purplish. Berry depressed, with ten furrows; having ten cells, filled with smooth seeds. It flowers in july and august, and in warm seasons the berries ripen in autumn.

[It is a very smooth plant, with an upright stem, frequently purple; the branches dichotomous at top. Leaves alternate, ovate, acute, quite entire, a little waved at the edge, on short petioles. Racemes solitary, opposite to the leaves. Peduncles striated. Pedicels spreading. Bractes awl shaped, pressed close. Calyx (or corolla) white or purple, five-parted; segments ovate, blunt. Filaments a little longer, five alternate and five opposite. Berry blackish blue, marked with ten or twelve grooves, one-celled, and containing ten or twelve seeds, which are semi-orbiculate, convex and thicker on one side, disposed in a ring in one row, adhering to the central receptacle[4].

Native of Switzerland, Spain and Portugal; Barbary, near Algiers; Virginia, Georgia, New England; Jamaica.—It was cultivated here in 1640, as appears from Parkinson[5]; who informs us that the inhabitants of North America use the juice of the root as a familiar purge.—An ounce of the dried root, infused in a pint of wine, and given to the quantity of two spoonfuls, operates kindly as an emetic, and is preferable to most others, as it hardly alters the taste of the wine. The roots are applied to the hands and feet in ardent fevers. Farriers give a decoction of them to drench cattle; and apply them in form of poultice for discussing tumours. Poultry are fond of the berries, but if eaten in large quantities, they give the flesh a disagreeable flavour[6].] The juice stains paper and linen of a beautiful purple colour, but it will not last long; if a method could be found of fixing the dye, it might be very useful.

[1] Retzius. [2] Linn. spec. [3] Hort. kew.
[4] Desfontaines. [5] Hort. kew.
[6] Cutler, mem. amer. vol. 1.

The vignerons in Portugal for many years uſed the juice of theſe berries to give a deep colour to the red Port wines, to which it was thought to communicate a diſagreeable taſte when mixed in too great a quantity. Complaint of this practice having been made to government, orders were given, that the ſtems of this plant ſhould be cut down and deſtroyed before they produced berries.

In North America and the Weſt Indies the young ſhoots are boiled and eaten like Spinach.

4. This plant is annual, always periſhing ſoon after it has perfected ſeeds. It riſes with an herbaceous ſtalk, from two to three feet high, with ſeveral longitudinal furrows, and changes at the end of ſummer to purple. It divides at top into three or four branches. Leaves lanceolate, ſix or ſeven inches long, and almoſt three broad in the middle, of a deep green, on ſhort foot-ſtalks; ſome are alternate, others oppoſite, and they are frequently oblique to the foot-ſtalk. The peduncles come out from the ſide of the branches oppoſite to the leaves; they are nine or ten inches long, the lower part being naked, but for a ſhorter ſpace than in the other ſorts: the upper part narrow and commonly inclined. The flowers are larger, white within, of an herbaceous colour on their edges, and purpliſh on the outſide, on ſhort pedicels. The ſtamens vary in number from eight to nine or eleven: [in the lower flowers, according to Linneus, there are certainly twenty; and Gærtner affirms that they vary from eight to twenty. Berry globular, ſcarcely depreſſed, not grooved, hollowed at top with a ſmall point, and terminated by ten permanent ſtyles, ſmooth, blueiſh black, pulpy, ten-celled: ſtyles clothed with their proper membrane, which is very tender: pulp dark blood-red. Seeds ſolitary, lens-ſhaped, very ſhortly beaked, ſmooth, ſhining, black, faſtened to the bottom of the cells near the axis of the fruit [a].] Theſe berries are very ſucculent, and their juice ſtains paper and linen of a beautiful purple colour, but it is not permanent.

[Native of the Eaſt Indies. Cultivated by Mr. Miller in 1758 [b].

5. This is a ſhrub, a fathom in height. Stem upright, rude, rubercled, aſh-coloured. Leaves alternate, ovate, entire, acuminate, acute at the baſe, thickiſh, ſpreading, permanent, four inches long, from eighteen to twenty-four lines in breadth. Petioles round on one ſide, channelled on the other, pubeſcent, one-third of the length of the leaf. Racemes terminating, but by a branchlet puſhing out from the uppermoſt axil they become lateral, and at the ſame time oppoſite to a leaf; they are upright, but when in fruit nodding or pendulous, on ſhort peduncles, villoſe, bracted, ſix inches long. Flowers ſcattered, on ſhort pedicels, herbaceous, three lines wide. Bracte acute, ſmall, under each pedicel; with other very minute bractes on the pedicel itſelf. Calyx (or corolla) five-parted to the very baſe. Filaments commonly fifteen, ten of which are alternate in pairs, the other five ſolitary, ſhorter than the calyx, inſerted into the bottom of the calyx, ſpreading, permanent; ſometimes there is only a ſingle row, and then there are but ten ſtamens. Germ roundiſh with from five to eight corners. Styles as many as there are ſwellings in the germ, moſt commonly five. Berry roundiſh, flattened, many-angled, but commonly five-angled, five-celled, marked at top with lines from the ſtyles then growing to the berry, fleſhy, ſoft, red, with a ſaffron-coloured juice, four lines in diameter. Seeds ſolitary, kidney-form, black. It is diſtinguiſhed from *Ph. ottandra* and *decandra* by its ſhrubby ſtalk, and decandrous flowers.

Native of Abyſſinia, where it was found by James Bruce, Eſq. and by him the ſeeds were communicated to the Paris garden [c], and to the Royal garden at Kew in 1775. It flowers in may and june [d].

6. This is a ſhrub two fathoms in height. Stem upright, a little branched, very thick, gray. Leaves ſcattered, oblong-ovate, acuminate, entire, ſmooth, flat or aſcending on the ſides, five inches long, and two inches and a half wide. Petioles ſpreading, cylindrical, reddiſh, equal to half the leaf in length. Racemes terminating, peduncled, ſolitary, pendulous, bracted, ſix inches long. Flowers ſcattered, pedicelled, ſpreading very much, whitiſh green; the males five or ſix lines in breadth, the females ſmaller by half. Bracte ſmall, acute, under the pedicel; with another under ſome flowers of the ſame ſhape with the calyx. Calyx (or corolla) five-leaved. Stamens about thirty, and a rudiment of a germ in the male flowers. In the females a head, compoſed of from ten to twelve germs, and as many ſtyles as there are ſwellings. Berry orbicular-flatted, umbilicated, toruloſe, many-celled or compoſed of united *acini*, fleſhy, ſoft, watery, ſeeming to be green even when ripe, half an inch in diameter. Seeds ſolitary, kidney-form, ſhining, brown. Both male and female plants flower every ſpring in the Paris garden, but ſtill the latter has continued barren [e].

It is a native of South America, and was cultivated by Mr. Miller in 1768 [f].]

PROPAGATION AND CULTURE.

3. Sow the ſeeds in the ſpring upon a bed of light earth, and when the plants come up tranſplant them into the borders of the flower-garden, allowing them ſpace to grow, for they will overbear other plants, if they are too near them, eſpecially if the ſoil be good. Clear them from weeds, and in the autumn they will produce flowers and fruit. The firſt froſts will deſtroy the ſtems, but the roots will abide, and ſhoot in the ſpring. In very ſevere winters the roots will be deſtroyed, eſpecially in a wet ſoil, unleſs the ſurface be covered with mulch.

2. 4. Theſe being leſs hardy, the ſeeds ſhould be ſown upon a moderate hot-bed in the ſpring. When the plants are fit to remove, tranſplant them into another hot-bed, ſhading them till they have taken new root. Then treat them as other tender exotic plants; and at the beginning of july, ſet them out upon a warm border, or in pots filled with light rich earth, and ſhaded till they have taken new root: water them duly in dry weather, and keep them clean from weeds. Theſe plants perfect their ſeeds every autumn, and may therefore be eaſily preſerved.

6. Plant cuttings during the ſummer months, in pots filled with light earth, and plunged into a moderate hot-bed, covering the pots with hand-glaſſes, and ſhading them. In five or ſix weeks they will put out roots; then plant each in a ſmall pot, plunge them into the bed again, ſhade them till they have taken root, and then gradually inure them to the open air, where they may remain to the end of ſeptember, when they muſt be removed into a moderate ſtove for the winter ſeaſon.

PICEA. See *Pinus*.

DESCRIPTIONS, &c.

1. This is a ſmall tree, with an upright weak even trunk: branches ſubdivided, rod-like, ſpreading, bending down, ſmoothiſh, with an aſh-coloured bark. Leaves pinnate, a foot long and more: leaflets petioled, alternate, elliptic with a blunt tip, entire, nerved and veined, ſmooth, bent down each way by the ſide of the petiole. Petioles roundiſh, ſpreading, ſmooth: petiolets very ſhort, pubeſcent, red. Racemes terminating, from one to two feet in length, filiform, ſtriated, looſe, pendulous, many-flowered. Flowers alternately conglomerate, peduncled, whitiſh-green. Peduncles from five to ſeven, cluſtered, whitiſh, longer than the flowers. Males deciduous. Calyx three-parted. Petals three. Filaments three. Anthers ruſous. Females the ſame ſize with the males. Berries oblong, the ſize of a Gooſeberry when ripe, two-celled: cells two-ſeeded, at firſt ſcarlet, afterwards black. Native of Jamaica and Hiſpaniola, in mountain coppices [x].

Dr. Browne ſays it is pretty frequent about St. Mary's in Jamaica, and ſeldom riſes above eight or nine feet from the ground; it was not put to any uſe there. Swartz relates, that it is looked upon by the negroes as antivenereal, and that they commonly uſe an infuſion of it in the colic. The whole plant is very bitter, and is called *Mojo Bitters* in Jamaica. It flowers in auguſt, and the fruit is ripe in november [y].

Browne uſes Burman's appellation, as more expreſſive of the virtues of this plant, which he thinks ſhould be the principal ſource whence the names of vegetables ought to be derived, when they are remarkably noted for any.

2. This alſo is a ſmall tree, with the branches, branchlets and leaves as in the preceding; but the leaflets are commonly wider. Racemes much ſhorter, commonly ſubdivided at the baſe, nodding. Flowers a little ſmaller, alternately cluſtered; (in ſcattered little balls) pedicels pubeſcent. Calyx five-parted. Petals five. Filaments five. Anthers roundiſh. In the female flowers the calyx is permanent. Germ roundiſh, without any ſtyles; but two-headed ſtigmas.

Native of the Weſt Indies: found by Ryan at Palmeto point in the iſland of Montſerrat [z].

PICRIS. (*Picris of Dioſcorides: from πικρος, bitter.*)

DESCRIP-

DESCRIPTIONS, &c.

1. Root annual, branched. Root-leaves ovate, crenate, rigid, with numerous warty protuberances, set with short spinose ciliæ; as are also the nerves and margins of the leaf. Stem two or three feet high, round, firm, striated, usually reddish, much branched; both stem and branches irregularly set with scattered rigid spines, hooked at the end. Stem-leaves embracing, oblong or cordate-lanceolate, pointed, entire, thick set with tubercles and spines, particularly on the margins and midrib. Flowers solitary, on grooved peduncles gradually thickening upwards. Leaves of the outer calyx very spreading, heart-shaped, acuminate and ending in a sharp awn, fringed with rigid ciliæ: scales of the inner calyx ciliate on the back. Corolla yellow. Seed shining, of a red orange colour, and when viewed with a glass very beautiful from its numerous transverse streaks or grooves. Down the length of the inner calyx, on a stipe three or four lines in length; rays downy [a].

The flower expands at four or five in the morning, and never closes before noon; sometimes it remains open till nine at night [b].

It grows not unfrequently on banks, on the edges of corn fields, and in woods that have been cut down; flowering in june and july.

The only use to which this singular plant has been applied is as a pot-herb, to which purpose its appearance is certainly no recommendation [c]. It can only be eaten when young, and then it is said to be agreeable; the juice is milky, but not too acrid [d].

2. The root-leaves and lower stem-leaves obovate-oblong, blunt, running down into a short petiole, unequally toothed, having short stiff hairs scattered over them. Stem upright, firm, thick, striated, rough, hispid, having on it a few, small, lanceolate, sessile leaves. Flowers in a loose corymb. Peduncles thickened upwards, hairy, simple or forked, unequal. Calyx round, loose: leaflets linear-lanceolate, hairy on the back. Corolla yellow. Down stiped, white, feathered. Seeds brown, slightly striated transversely [e].

It differs from the preceding in having no outer five-leaved perianth [f].

Native of Barbary. Vahl found it near Zowan, a city of Tunis; and Desfontaines on mount Atlas and uncultivated hills of that country.

3. This is a plant of rude growth, and not very attractive appearance. The root is perennial, or at least biennial. Stem three feet high, round, furrowed, rough with stiff hairs; much branched; the branches furrowed, purple on their upper side and in their axils, as Linnæus most truly observes. Lower leaves on foot-stalks; upper sessile, oblong or lanceolate, acute; uppermost approaching to linear; all mostly undivided, except that the root-leaves are frequently grossly toothed. The herb is rough with hooked bristles. Peduncles branched: each branch bearing a single flower; the lateral ones elongated so as to rise above the central stem. Calyx scarcely to be called double; numerous loose scales, all rough on the back, on the upper part of the peduncle approaching to, and at length imbricated with, and forming a part of the calyx: the inner row almost linear, parallel, and exactly the length of the seed-down, which is slightly feathery and sessile; whence Hudson has made this plant a *Hedypnois*: but that, as Dr. Stokes has observed, is an artificial genus, the species of which are no ways naturally allied; and the down being sessile or stiped, affords no certain permanent character in this tribe.

The corolla is bright yellow; and the seeds are longitudinally and transversely furrowed [g]. According to Gærtner, they are uniform, oblong, roundish, drawn to a point at both ends, netted and rugged, but without any lateral sutures: the down is twice as long as the seed, and has the rays filiform, regularly bearded. Receptacle flat, with shallow pits inclining to a pentagon figure, and between them a minute tear. It differs from his *Picris* in having the rays of the down uniform; and from his *Helminthia*, in the down being not apparently stiped.

Native of many parts of Europe; with us it occurs abundantly about the borders of fields, in a gravelly or calcareous soil, flowering in july and august.

4. Stem grooved and angular, flexuose, bristly-hispid, branched at top, almost erect, scarcely a foot high. Leaves alternate, all sessile and embracing, subcordate, oblong, villose and rugged, the lower ones a finger's length, the upper ones gradually smaller. Flowers on the branches terminating, solitary. Peduncles or branches alternate, simple, hispid. Calyx double, the lower reflex. Corollas yellow, with a white feathered down.—Native of Japan [h].

5. Root perennial, fusiform, the thickness of a man's little finger. Stems several, prostrate at the base, rough-haired especially at bottom, angular, grooved, branched below: branches ascending, simple. Root-leaves many, wide, runcinate, the sinuses bowed: lobes irregular, rounded at top, unequal, often turned back, sometimes narrower at the base; the outmost larger, blunt. Peduncles one-flowered, striated, hispid, simple, firm, erect, gradually thicker upwards, covered with linear-spatulate, blunt, scattered leaflets, somewhat remote from each other. Calyx cylindric, imbricate, hispid: leaflets lanceolate-linear, obtuse; the outer reflex at the tip, and somewhat rigid. Flower the size of Tragopogon Dalechampii: corollets sulphur-coloured above, rose-violet underneath. Seed smooth, rufescent, oblong, slightly streaked across. Down stiped, feathered, white. Receptacle naked, flattish [i].

Native of Barbary; found by Vahl abundantly on the sandy coast of Tunis; and by Desfontaines near Hamamelif.

See L'Heritier's description of this plant under *Leontodon muricatum*.

6. Stem procumbent, slender, round, smooth. Leaves lanceolate linear, blunt, repand, toothletted, smooth. Flowers few, yellow, on long, scattered peduncles, almost equal to the leaves. Calycle short, imbricate: inner calyx oblong, round, eight-leaved; leaflets linear, even, equal. Down subplumose, stiped. Seeds grooved longitudinally, not transversely. Root slender, very bitter.—Native of China near Canton [k].

Picris pyrenaica of Gærtner; see under *Hieracium pyrenaicum*.—Receptacle flat, obsoletely excavated, smooth. Seeds roundish, drawn to a point at both ends, divided by four longitudinal depressed streaks, as it were into so many valves, and besides this muricated with thick transverse wrinkles, of a red ferruginous colour: the marginal seeds curved; those in the centre straight. Down feathered, subsessile, longer than the seed, caducous; all the rays filiform, equally bearded [l].

SPECIES.

1. Picrium spicatum.
Coutoubea spicata. *Aubl. gui.* 1. *p.* 72.
With ovate-oblong sharp leaves, and white flowers.

2. Picrium ramosum.
Coutoubea ramosa. *Aubl. gui.* 1. *p.* 74.
With narrow sharp-pointed leaves, and purple flowers.

DESCRIPTIONS, *&c.*

1. This is an annual, of about three feet high. The root is fibrous, branched, and somewhat woody. The stem round and straight: leaves opposite, rather fleshy, sessile, smooth, glaucous, lanceolate, perfectly entire, sometimes ternate, verticillate. Flowers spiked, axillary, and terminal: the inferior ones opposite in the spike, afterwards alternate; the four uppermost verticillate: all sessile at the base, and guarded by three bractes, of which the two lateral ones are smaller. Corolla white, not deciduous. The whole plant is bitter: it flowers at various times of the year. Its native name is Coutoubea. It is found near the banks of rivulets, pathways, &c. in Cayenne and Guiana.

2. This species differs from the former in having a branched stem, smaller and narrower leaves; solitary flowers, which are subsessile at the bosoms of the leaves, and have a purple corolla. The capsule is subcompressed: the leaves at the extremities of the branchlets are extremely narrow. It flowers at almost all times of the year, and is called Coutoubea also. It is found in woods and by sides of rivulets[m].

Euonymus latifolius racemosus, fructu pentagono atropurpureo. *Plum. spec.* 18. *ic.* 119. *t.* 127.

DESCRIPTION, *&c.*

This is a low Shrub, with round, smooth, pendulous branches, covered with an ash-coloured bark, and alternate, short, purplish-brown branchlets. Leaves on the latter, approximating, alternate, the two last almost opposite, two or three inches long, elliptic, very obtuse, commonly emarginate, more acute at the base, quite entire, membranaceous, smooth, veined, very minutely dotted on both sides. Petioles very short, smooth, flat above, convex underneath, purplish-brown. Stipules none. Racemes from the top of the branches, with a branchlet growing out at the farther side, solitary, a foot long and more. Peduncle straight, round, smooth, purplish brown. Pedicels scattered, about an inch in length, spreading very much, one-flowered. Bractes two above the middle of the pedicel, very minute, ovate, alternate, remote. Flowers bright purple. Petals terminated by a minute dagger-point, and having on the upper surface a longitudinal line, a little raised, springing from the tip, forked towards the middle of the petal, the divisions divaricating and running to the edges of the petal. Anthers of a deep golden colour, and shining very much. The cocculi or component parts of the capsule semiorbicular, more gibbous at the base, convex on the back and sides, more acute on the inner margin, the outer substance somewhat fleshy, the inner coriaceous; at first they have impressed dots scattered over them, but when ripe they are grooved longitudinally archwise, and open with a spring at top by the future. Seeds black and very smooth. Aril membranaceous, cordate, acute, keeled on the outside, closing the ventral triangular aperture of the inner cocculus.—Native of the West Indies. Found by Ryan in the island of Montserrat*.

Gramen piperinum. *Merr. pin. Petiv. brit. t.* 9. *f.* 8.

DESCRIPTION, *&c.*

Stem perfectly prostrate and trailing, throwing out numerous roots at every joint, by which it creeps to a considerable extent, and also about three delicate slender leaves, two or three inches in length, simple, upright, awl-shaped, smooth. Fructifications globular, like pepper-corns, downy, solitary, sessile or on very short pedicels at the base or axil of the leaves. What at first sight seems a capsule, is in fact a hollow receptacle, as in the Fig, which separates into four valves, and is internally divided into as many cells: the valves are lined with organs of fructification, several sessile club-shaped anthers being in the upper part, and about as many oblong germs occupying the lower. Jussieu says the anthers are most numerous; he also remarks that the seeds are coated. Mr. Sowerby found the germs shaped like an Acorn reversed, and terminating in a small acute style.

From the above description it appears that the *Pilularia* has almost as good a right to a place among the perfect flowers as the Fig, and might perhaps be ranged in the order *Polyandria* of the class *Monoecia.* In habit and sensible qualities it has most affinity with the *Equisetum, Lycopodium* and other plants of obscure fructification, which are akin to the proper Ferns. The fructification is produced from may to the end of autumn. It is found in shallow ponds, and watery places, on gravelly or sandy commons or heaths. On Hillingdon-common and Hounslow-heath in Middlesex.

[m] Aublet.

* Vahl.

Near Yarmouth in Norfolk, St. Faith's Newton near Norwich[a]: Hainford and Stratton heaths in the same county. In the ponds on the upper part of Streatham-common in Surrey, I observed it near fifty years ago; where Plukenet had before shewn it to Doody. About two miles from Mold, on the north side of the Chester road, near Offa's dyke, by Mr. Griffith.

   Banksia Gnidia. *Forst. gen.* 8. *act. upf.* 3. 173.
   Passerina Gnidia. *Lin. suppl.* 226. *Forst. prodr. n.* 170.
   Leaves oblong-lanceolate acute very smooth, corolla villose on the outside.
3. Pimelea pilosa.
   Lin. spec. ed. Willd. 50.
   Banksia tomentosa. *Forst. gen.* 8.
   B. pilosa. *Forst. act. upf.* 3. 174.
   Passerina pilosa. *Lin. suppl.* 226. *Forst. prodr. n.* 171.
   Hairy, leaves linear obtuse.
4. Pimelea prostrata.
   Lin. spec. ed. Willd. 51.
   P. lævigata. *Gærtn. fruct.* 1. 186.
   Banksia prostrata. *Forst. gen.* 8. *act. upf.* 3. 175.
   Passerina prostrata. *Lin. suppl.* 227. *Forst. prodr. n.* 172.
   Leaves ovate sessile fleshy.

DESCRIPTIONS, *&c.*

1. This is a native of the coast of New South Wales, among rocks. It has a small zigzag root, from which rises a straight round smooth upright stem, generally branched in an irregular manner, though sometimes appearing dichotomous, in consequence of the young branches springing in pairs from the upper part of the old flowering ones: the bark is reddish, cracking longitudinally, and its inner layer is remarkably silky. Leaves clothing the younger branches, opposite, on very short footstalks, slightly spreading, linear-lanceolate, varying much in breadth, sharpish, entire, with a simple nerve. Stipules none. Flowers in terminal heads, numerous, inodorous. Bractes four, broad, ovate, entire, close to the flowers. Corolla very slender, tubular, snow-white, externally silky; the limb in four equal ovate spreading segments, with a red spot at the base of each within side. Stamens two, their filaments rather shorter than the limb, and inserted into the base of its two segments, so that they are altogether without the tube, and not within it, as in Daphne, Passerina, &c. Anthers oblong, yellow. Germ superior, oval, green, very small, smooth. Style rather longer than the tube, simple and capillary. Stigma headed, very small. Fruit a small oval dry berry or rather drupe, invested with the permanent base of the corolla, and containing a solitary hard seed or nut. Common receptacle clothed with numerous white permanent hairs[b].

2. The leaves of this are more rigid than the others, and resemble very much those of *Gnidia*, whence its trivial name. It is a native of New Zealand, in the fissures of rocks, both on the coast and on the tops of mountains.

3. This also is a native of New Zealand, where it was found, with the preceding and following species, by Forster[c].

4. Gærtner thus describes the fruit of this, from the Banksian collection. Nut superior, small, clothed with the permanent silky-white corolla, ovate-acuminate, covered with a thin coriaceous rind: shell somewhat bony, brittle, brown, having a moderately elevated longitudinal streak on one side, in the other parts smooth, one-celled, valveless. Seed one, of the same size and form with the cavity of the shell, pale.

The corolla is one-petalled, ventricose, narrowed and funnel-form at the throat; the four segments ovate-oblong. Stamens in the throat of the corolla.

Found by Forster on the dry mountains of New Zealand.

These plants are united by the younger Linnæus with the genus *Passerina*, because he was not willing to break a natural genus, on account of a diversity in the number of stamens. He remarks that the flowers have the odour of Syringa, and that the plants are evergreen[d].

PIMENTA and PIMENTO. See *Myrtus*.

PIMPERNEL. See *Anagallis*.]

PIMPINELLA. (*For* Bipennula. *Linn. from its pinnate leaves.*)

DESCRIPTIONS, &c.

1. Root perennial, ſtrong, woody, highly aromatic and pungent, to ſome perſons not unpleaſant, eſpecially when dry. Stems about a foot high, erect, ſlender, rigid, round, ſtriated and roughiſh, varying much in luxuriance, generally branched above. Leaves on long footſtalks, veiny, roughiſh, and rigid; the leaflets of the firſt root-leaves roundiſh or ovate, acutely ſerrate and generally deeply notched, eſpecially that at the end; the other leaves are compoſed of decurrent, linear, often falcated, ſometimes twice pinnatifid leaflets, thoſe which grow high on the ſtem being the narroweſt and moſt ſimple, and their common footſtalk more membranous and dilated than in the reſt. Umbels drooping when young. Flowers ſmall, white with long ſtamina: top of the germ very rumid and reddiſh. Styles ſhort. Seeds ſmall*.

There is a wonderful diverſity in the ſize and foliage of this ſpecies. It often happens that the root-leaves become like thoſe of the ſtem, and then it has been ſuppoſed to be a diſtinct ſpecies. I ſhall not attempt to follow this Proteus through all its changes: and have only given above our common ſort here deſcribed, the *nigra* and the *diſſecta*, which are ſet down by ſome for diſtinct ſpecies.]

β. Mr. Miller ſays, that the ſeeds of the *nigra*, or black-rooted German Burnet-Saxifrage, were ſent him from Paris by Bernard de Juſſieu; that the lower leaves are compoſed of ſix or ſeven pairs of leaflets terminated by an odd one; that they are heart-ſhaped, almoſt two inches long, and an inch and half broad near the baſe, hairy and of a pale green; that the ſtalk riſes near two feet high, dividing into ſeveral branches, which have one narrow five-pointed leaf at each joint, and are terminated by umbels of white flowers, like thoſe of P. magna, of which this may perhaps rather be a variety. [Willdenow diſtinguiſhes it by the pubeſcence of the ſtem and leaves; the root leaflets are ſubcordate, gaſhed, blunt and toothed, the ſtem-leaves bipinnate and linear; the root when cut or wounded pours out a blue milky liquor. It is a native of Germany in dry ſoils.

γ. Retzius, who has figured this ſays, that the root-leaves of the firſt year are entirely pinnate, and the pinnas roundiſh; but when theſe decay, the pinnas are all many-parted, and the ſegments ſubfalcated and acute. He remarks farther, that in a garden it grows taller, and the ſtem is ſtiffer, but in other reſpects it does not undergo any change. It is a native of Germany and Sweden.

We have it alſo in England. It is the fifth variety of Withering, who deſcribes the "root-leaves as "doubly-winged, the leafits wing-cleft, with entire "ſegments; ſtem-leaves doubly winged, with entire "leafits; floral leaves cloven at the end."

He diſtinguiſhes four other varieties:

1. With all the leafits egg-ſhaped, ſerrate. For this he refers to the following figures: *Tabern. ic.* 88; 255, 1 & 2. *Germ. edit. Ger.* 887. 1 & 2. *Bauh. hiſt.* 3. 2. 111. 1 & 2. *Mor. hiſt. ſ.* 9. *t.* 5. *f.* 6. *Trag.* 466. *Fuchſ.* 609. *Matth.* 1032.
2. Leafits on the root-leaves egg-ſhaped, ſerrate, thoſe on the ſtem-leaves ſtrap-ſhaped (linear) moſtly entire, floral-leaves ſtrap-ſhaped. This is figured by Jacquin, *auſtr.* 395. *Cluſ.* 2. 197. 2. *Dod.* 315. 2. *Lob. obſ.* 413. 1. & *ic.* 719. 2. *Ger. emac.* 1044. 2. *Park.* 947. 4. *Cam. epit.* 776.
3. Leafits on the root-leaves egg-ſhaped ſerrate, on the lower ſtem-leaves deeply wing cleft, floral leaves winged.—Figured in *Flor. dan.* 669. *Blackw.* 472. *Riv. pent.* 8. *P. minor.*
4. All the leaves doubly winged, leafits ſtrap-ſhaped moſtly entire, floral leaves winged. From Mr. Relhan. No figure.

The ſixth variety belongs rather to P. magna.

All the above varieties, he adds, are probably occaſioned by the different age of the plant, and the greater or leſs expanſion of its foliage, according to the ſoil in which it grows. It is probable that the firſt root-leaves are the ſame in all, that is ſimply winged, the leafits egg-ſhaped and ſerrate: when theſe diſappear, the lower leaves have wing-cleft or doubly winged leaves, and the upper leaves become alſo more compound than the reſt.

* Engl. bot.

Common Burnet Saxifrage is a native of moſt parts of Europe, in dry gravelly or calcareous paſtures; flowering from midſummer through the autumn.

Mr. Miller's P. hircina, is nothing more than P. ſaxifraga β. of Hudſon—hircina minor of Parkinſon. *Ray ſyn.* 213. 3.

2. Root perennial, woody, like that of *P. ſaxifraga* in flavour, but rather weaker. Stem two feet or more in height, round, ſtriated. Leaves on rather ſhorter footſtalks than in the preceding, pinnated, but of fewer leaflets (ſcarcely more than three pairs), and thoſe larger, ovate or ovate-lanceolate, the terminating one more or leſs deeply three-cleft, and all ſtrongly ſerrated. Sometimes, it is ſaid, the upper leaves are deeply pinnatifid, but that is not generally the caſe. Flowers commonly white, about the ſize of the laſt, and like them in ſtructure; but in alpine ſituations they often become roſe-coloured [a]. The ſtem-leaves are gradually narrower as they are higher up; at length linear and almoſt entire. The univerſal umbel has fourteen, the partial from ten to eighteen rays, in the preceding both have from eight to twenty rays [b].]

Mr. Miller remarks, that the lower leaflets, which are the largeſt, are near two inches long, an inch and half broad at their baſe, and of a dark green, and that white and red flowers riſe from the ſame ſeed.

Native of the South of Europe, Germany, Switzerland and England. With us it grows chiefly in woods and hedges in a calcareous ſoil, flowering in auguſt or even later. Ray marks it to grow in the woods of Cambridgeſhire, Bedfordſhire, Kent, &c., Mr. Woodward in Ripton-wood, Huntingdonſhire, Mr. Ballard in Worceſterſhire, Dr. Pulteney in Hollinghall-wood, Leiceſterſhire, Mr. Robſon about Thirſk and Burroughbridge in Yorkſhire, Dr. Smith under the walls of York, Dr. Milne near Clandon-place in Surry, in Petworth-park, near Lord Petre's at Brentwood, at Greenhithe, by the 31ſt mile-ſtone on the Canterbury road, on Hampſtead-heath, at Leads near Claremont in Surry, about Guildford and Godalmin, between Wimbledon and Merton, Dr. Sibthorp in Stow-wood and Noke woods, Oxfordſhire. In Wedneſbury-field, Staffordſhire, with a red flower. In hedges near Maidſtone, Kent, with all the leaves jagged.

This and the former ſpecies partake nearly of the ſame qualities. The root is very acrid, burning the mouth like Pepper. It affords a blue oil. Its acrimony has occaſioned it to be uſed to cure the tooth-ache, and to cleanſe the ſkin from freckles. It is chewed to promote the ſecretion of ſaliva, and is uſed in gargles for diſſolving viſcid mucus in the throat. In Germany it is preſcribed in the aſthma and dropſy [c].

β. Root biennial, branched. Stem grooved and angular, panicled with branches. Primary root-leaves having five petioled leaflets, the lower cordate crenate, the middle obliquely ovate, the end one ovate equal three-lobed crenate; the ſecond root-leaves quinate alſo, but the two lower leaflets three-parted-palmate multifid, the middle ones ſmaller and leſs jagged, having a ſeſſile oblong leaflet at the baſe longitudinally truncate upwards; the odd leaflet three-lobed. The ſecond year the root-leaves or lower ſtem-leaves have ſometimes ſeven leaflets, but moſt commonly five, the loweſt ternate, the reſt three-parted multifid, deeply pinnatifid, almoſt like *Aconitum Napellus*. The other ſtem-leaves and branch-leaves have much ſmaller leaflets; and the uppermoſt are very ſmall, trifid and ſcarcely jagged. The petioles of the root-leaves are three inches long, three-ſided and grooved above; the ſheaths ſtriated-nerved and wide, frequently purple. The umbels have from fourteen to ſixteen rays, about half an inch in length but ſomewhat unequal. The umbellets have about ſixteen very ſlender rays, two lines long. Flowers white. Seeds ſmooth [d].

Found by Tournefort in the Levant, and by Jacquin in Auſtria.

[a] Engl. bot. [b] Relhan. [c] Withering. [d] Gouan.

Mr. Miller's *P. auſtriaca* is probably a variety of the *magna*, but it does not correſpond with the *orientalis*: as far as we can judge by his deſcription.] The lower leaves have five pairs of leaflets, with an odd one; they are placed at a wider diſtance than the other ſorts; are near two inches long, and three quarters of an inch broad in the middle, drawing to a point at each end, and are deeply cut in regular jags oppoſite; they are of a lucid green and are placed on long foot-ſtalks. The ſtems are two feet high, divide at the top into two or three ſlender branches, and at each joint have one pinnatifid linear leaf. Mr. Miller gathered the ſeeds in Boerhaave's private garden near Leyden, under the name of *Tragoſelinum auſtriacum maximum, foliis profundiſſime inciſis*.

[3. Leaves nearly thoſe of *P. magna*. Root-leaves pubeſcent, petioled: leaflets unequally and bluntly toothed, often gaſhed in front: terminating leaflets commonly three-lobed. Stem ſmooth, even, leafy below, leafleſs above and branched: branches dichotomous; branchlets filiform, panicled. Sheaths channelled, entire, membranaceous, deciduous. Peduncles nodding. Umbels ſmall. Rays three to five, capillary. Petals yellow, very ſmall. Filaments of the ſame colour. Seeds quite ſmooth, ſmall, half ovate, ſcarcely ſtriated. Central florets abortive. It flowers in ſummer, and has an aromatic odour.—Native of mount Atlas [a].

4. Root fuſiform, fibrous, brown without, white within. Stem erect, ſeldom attaining a foot in height, four or five-cornered, very ſmooth, divided from the very baſe into ſmaller branches, and into very ſmall ones much diverging. Leaves alternate, the lower petioled, the upper oppoſite or in threes ſeſſile, near four inches long, two inches wide, the laſt pinnas ſhort, twice-trifid, linear, ſomewhat fleſhy, quite entire, all glaucous-green and ſmooth. Sheaths ſtriated, ſmooth, with a white membranaceous margin. Peduncles angular, ſmooth. The univerſal umbel has about ten rays, the partial ſeventeen or more. Flowers ſmall, white [b]. It is not a ſpecies of *Seſeli*, becauſe it has no partial involucre [c]. Gouan affirms, that it has involucels, which are ſometimes deciduous, ſometimes permanent, but that the latter are ſo ſmall as not to be ſeen without a magnifier, or when the fruit is ripe.—Native of Germany, France and Italy.

5. Found at the Cape of Good Hope by Thunberg [d].

6. Root long, white and fibrous; of a very ſharp taſte. Radical leaves (at leaſt when raiſed in a garden) proſtrate, and numerous; thoſe which appear firſt are ſimple, the next ternate, and the ſucceeding ones pinnate: leaflets roundiſh and crenated. Stem ſolitary, two feet high, ſtriated, and branched above; it has but few leaves, the lower ones of which reſemble more or leſs the radical ones; but the upper ones are variouſly divided into lanceolate ſegments. The umbels nod extremely before flowering, and afterwards are upright. The flowers are white, and the petals hairy on the back. The fruit is very ſmall, and ovate-roundiſh, crowned with the two ſpreading ſtyles, and ſeparable into two brown ſeeds, flat on one ſide, and gibbous and ſtriated on the other, and beſet with numerous pale briſtles: they have no ſmell, and when firſt chewed, ſcarce any taſte, but in a ſhort time are very acrimonious, and excite a great heat in the fauces [e].

Native of Italy and Spain. Cultivated in 1739, by Mr. Miller [f].]

7. Root annual. Lower leaves divided into three lobes, which are deeply cut on their edges. Stem a foot and half high, dividing into ſeveral ſlender branches, which have narrow leaves on them, cut into three or four narrow ſegments. Umbels pretty large and looſe, on long peduncles. Flowers ſmall, yelloviſh white. Seeds oblong, ſwelling. It flowers in july, and if the ſeaſon prove warm, the ſeeds will ripen in autumn. It is a native of Egypt, but is cultivated in Malta and Spain, whence the ſeeds are annually

[a] Deſfontaines. [b] Pollich. [c] Linn. [d] Thunb. prodr. [e] Jacquin. [f] Hort. kew.

imported

imported into England. [It was in our gardens in 1551, as appears from Turner[1].

The ſeeds have an aromatic ſmell, and a pleaſant warm taſte, accompanied with a conſiderable degree of ſweetneſs. In diſtillation with water, three pounds of them yield an ounce or more of eſſential oil which, even when the air is not ſenſibly cold, congeals into a butyraceous white concrete. Its ſmell is very durable and diffuſive, and its taſte milder and leſs pungent than almoſt any other diſtilled vegetable oils.

Theſe ſeeds yield an oil likewiſe by expreſſion, of a greeniſh colour, and grateful taſte, ſtrongly impregnated with the flavour of the ſeeds: ſixteen ounces lightly moiſtened by expoſure to the ſteam of boiling water, are ſaid to afford one ounce, compoſed of a groſs inſipid inodorous oil, of the ſame nature with common expreſſed oils, and a part of the eſſential oil of the ſeed, on which the flavour depends.

The ſeeds of Aniſe have been long uſed by phyſicians as an aromatic and carminative, in preference to thoſe of moſt other umbellate plants; they have alſo been eſteemed good in pulmonary complaints, and like thoſe of Fennel, to promote the ſecretion of milk. Their chief uſe however is in flatulencies, and in the gripes to which children are more eſpecially liable; and they are combined with ſuch purgatives as are apt to produce theſe effects. Weakneſs of the ſtomach, diarrhœas, and loſs of tone in the primæ viæ are likewiſe complaints in which Aniſe-ſeeds are ſuppoſed to be peculiarly uſeful.

The eſſential oil, which is the only officinal preparation now directed by the Pharmacopœias, is uſually grateful to the ſtomach, and may be taken in the doſe of twenty drops. In diſeaſes of the breaſt the oil is preferred, but in flatulencies and colics the ſeeds in ſubſtance are ſaid to be more effectual.

It is aſſerted that the oil is a poiſon to pigeons[2].

8. This plant is half a foot high, very much branched, dichotomous. Lower leaves triternate, upper biternate, almoſt linear, ſhorter, acute; on petioles augmented on both ſides by a membrane wider than the others, quite membranaceous, white. Peduncles oppoſite to the leaf, and much longer than it, one from each axil, whence they are abundant. The univerſal umbels have five or ſix rays. Petals white, curved in and emarginate. Fruit ſubglobular, ſtriated. Native of Spain[3].

9. Root perennial, fuſiform, running ſtraight down, ſomewhat branched at the baſe, with a villoſe head. Stem from half a cubit to a cubit in height, upright, angular, ſtriated, leafy, ſmooth, very much branched; branches patulous. Lower leaves oppoſite, petioled, pinnate and bipinnate: leaflets ſimple and ternate, linear, channelled, naked, glaucous. Petiole membranaceous, ſheathing, oblong, ſtriated, entire. Umbels peduncled, axillary and terminating: univerſal of about ſix long rays; partial cluſtered, with about five ſhort rays. Flowers yelloviſh or whitiſh dioecous. Petals equal. The male flowers have no piſtil. The female flowers have anthers, but they are barren[4]. Mr. Swayne remarks, that the male plant has a yellow ſickly appearance[5].

According to Linneus, the ſtem is divaricating, even, ſtriated, with but few leaves. Leaves ternate or biternate, linear. Umbels one terminating and two lateral, oppoſite, generally compound, ſome few ſimple. Petals long-lanceolate, curved in but not emarginate. Filaments white, long. There is a male and an hermaphrodite plant. It is nearly allied to *P. glauca*, or of a diſtinct genus.]

Mr. Miller ſays it is a biennial plant, periſhing ſoon after it has perfected its ſeeds: leaves ſhort and very narrow, ſpreading near the ground; ſtems near a foot high, branched almoſt from the bottom; the branches are almoſt horizontal, and have a few narrow ſhort leaves of a lucid green: each ſtalk is terminated by a ſmall umbel of flowers of an herbaceous yellow colour and ſmall: they are ſucceeded by ſmall channelled ſeeds.

[1] Hort. kew. [2] Woodville. [3] Linn. mant. [4] Hudſon. [5] Withering.

[Native of Auſtria, Provence, Switzerland and England; on St. Vincent's rocks, near Briſtol, and above Uphill in Somerſetſhire. It flowers in May and june.]

PROPAGATION AND CULTURE.

Theſe are hardy perennials, except the fifth, which is a native of the Cape, and the ſeventh, which is an annual plant. They are propagated by ſeeds ſown in the autumn rather than ſpring. When the plants come up, thin them where they are too cloſe, and keep them clean from weeds: the ſecond year they will flower and produce ripe ſeeds. The roots will abide ſome years in poor land. The laſt ſort is biennial, (obſerves make it perennial) and rarely ripens ſeeds in a garden.

7. The ſeeds of Aniſe ſhould be ſown the beginning of april upon a warm border, where the plants are to remain; when they come up thin them and keep them clean from weeds. It is too tender to be cultivated in England for profit.

Scape ſtrict pubeſcent, nectary awl-ſhaped ſtraight very ſhort, leaves nerved.

DESCRIPTIONS, &c.

1. Root perennial. Leaves like thoſe of the other ſpecies, but rather more delicate and pellucid, reticulated with red veins, and much involute in the margin. Stalks hairy, eſpecially in their lower part, with ſhort ſpreading glandular hairs tipped with a viſcid fluid. Flowers a little nodding. Calyx ſcarcely two-lipped, but almoſt equally five-cleft. Tube of the corolla nearly cylindrical, yellow ſtreaked with red; limb in five equal obcordate ſpreading ſegments, of a pale lilac; orifice hairy; ſpur inflated at the baſe, then contracted, terminating in a very blunt conical figure, and when dried much thicker at the end than at the middle, ſtreaked with red. Stamens flattiſh. Germ hairy. Stigma blunt, excavated on the upper ſide. Capſule perfectly globular, crowned with the withered ſtigma.

To diſtinguiſh this ſpecies from others it may be remarked, that *P. vulgaris* has an unequal limb, ſharp ſlender ſpur, and oval capſule: *P. alpina* has a very ſhort conical ſpur, and a long roſtrated capſule: *P. villoſa* a ſlender ſharp ſpur, and obcordate compreſſed capſule, with ſhort round leaves. Its hairy ſtalk and regular limb agree nearly with *P. luſitanica*, but the *villoſa* is ſmaller in all its parts [a].

Ray had remarked that the leaves are almoſt pellucid, marked with purpliſh veins, and the edges rolled in; that the flowers are ſmaller with more of a reddiſh caſt than in *P. vulgaris*.

Found about Kilkhampton by Ray, and midway from Oakhampton to Launceſton by Merret; ſaid to be frequent in the weſtern counties by Hudſon; found in Stoneham-park, Hampſhire by Sir Joſeph Banks; Dr. Pulteney ſays it is abundantly more frequent in Dorſetſhire, on the borders of bogs, than *P. vulgaris*. Dr. Hope found it near Air in Scotland, and in the iſland of Lamlaſh; Mr. Stuart and Mr. Lightfoot in the Iſle of Skye: and Mr. Lambert on Croagh Patrick, in the county of Mayo, Ireland. It flowers in june and july.

2. This is a ſmooth plant. The leaves are leſs involuted. Scapes ſmooth, only a little pubeſcent at the top. Corolla violet-coloured, with an unequal limb: ſpur awl-ſhaped, acute. Capſule ovate [b]. The leaves are remarkably glutinous on their upper ſide, and afford a good example of an involuted margin. The ſtructure of the ſtigma, and its cloſe application to the ſtamens, are very remarkable [c].

Linnæus remarks that the ſoft upright prickles which cover the leaf, ſecrete the glutinous liquor; and that the corolla is violet, purple and reddiſh, with white lips, and an aſh-coloured woolly ſpot on the palate.

Native of many parts of Europe, on bogs. It is abundant in our northern counties, and Scotland; alſo in Norfolk; Cambridgeſhire at Hinton and Teverſham moors, and in the fens near Ely; in Bedfordſhire on Ampthill bogs, Mr. Abbot; on Bullington-green, and under Headington-Wick copſe in Oxfordſhire, Dr. Sibthorp; on the little bog by Charlton wood, near Shooter's-hill, on Pets-bog near Chiſelhurſt, and on the Mere near Feverſham, in Kent; at Harringay and Wellingborough in Northamptonſhire; at Baſford Scottum in Nottinghamſhire.

Gerarde ſets it down as growing in Crag-cloſe and at Croſby Ravenſwaith in Weſtmoreland, upon Ingleborough fells twelve miles from Lancaſter, and in Harwood in the ſame county near to Blackburne, ten miles from Preſton in Aunderneſſe; in the boggy meadows about Biſhop's Hatfield, and alſo in the fens in the way to Wittles meare from London in Huntingdonſhire. Johnſon adds, that it grows alſo in Hampſhire, and abundantly in many places of Wales.

It flowers in may and june.

In Yorkſhire, ſays Gerarde, where it doth eſpecially grow, and in greateſt abundance, it is called Butterworts, Butter-root, and White-root; but the laſt name belongeth more properly to Solomon's Seal. It is alſo named Yorkſhire Sanicle.

If the freſh-gathered leaves of Butterwort are put into the filtre or ſtrainer, through which warm milk from the Rein-deer is poured, and the milk is ſet by for a day or two to become acefcent, it acquires conſiſtence and tenacity, neither the whey nor the cream ſeparate: in this ſtate it is an extremely grateful food, and as ſuch is uſed in the north of Sweden. There is no farther occaſion to have recourſe to theſe leaves, for half a ſpoonful of the prepared milk, mixed with freſh warm milk, will convert it to its own nature, and ſo on. This has not ſucceeded when tried with Cow's milk. The juice of the leaves kills lice. The common people uſe it to cure cracks in Cow's udders [d]. This plant is generally ſuppoſed injurious to ſheep, and is called *White-rot*, from its occaſioning a diſeaſe which farmers call the rot. But it may be queſtioned whether the rot in ſheep be ſo much owing to the vegetables in marſhy grounds, as to the *Faſciola hepatica*, a flat inſect called a *Fluke*, from its ſimilitude to a Flounder or Fluke; and which is found in ſuch ſituations, adhering to ſtones and plants, as well as in the livers and biliary ducts of ſheep affected with the rot. From experiments made on purpoſe, and conducted with accuracy, it appears that ſheep, cows, horſes, goats and ſwine will not feed upon this plant [e].

3. The flowers are three times the ſize of thoſe of the preceding, of a violet purple colour: ſpur awl-ſhaped the length of the flower: upper lip dilated emarginate; lower wide, bluntly three-lobed, and not deeply three-parted, as in *P. vulgaris*.—Native of mountains in the South of France.

4. Corolla white with a reflex ſpur. Capſule beaked [f].—Native of the alps of Lapland, Norway, Switzerland, Auſtria, Germany, Dauphiné and Piedmont. It flowers earlier than the common ſort.

Villars remarks, that the flower is more open, the nectary ſhorter, and the leaves wider, leſs elongated and more yellow than the common ſort.

5. Scape ſetaceous, ſcarce apparently pubeſcent. Corolla violet-coloured, with the ſpur ſtanding out. It is ſix times leſs in all its parts than *P. vulgaris* [g]. It differs from *P. luſitanica* in having the ſcape ſtrict, the leaves three-nerved, and the flowers ſmaller [h].

Native of Lapland, Norway and Siberia.

PIST. *Germ* very ſmall. *Style* awl-ſhaped. *Stigma* ſimple.
PER. none. *Strobile* ſerves for a calyx, having before been cloſed, but now only converging.
SEED. *Nut* augmented by a membranaceous wing which is larger than the ſeed, but leſs than the ſcale of the ſtrobile, oblong, ſtraight on one ſide, gibbous on the the other.

ESSENTIAL CHARACTER.

MALE. *Cal.* four-leaved. *Cor.* none. *Stam.* very many, with naked anthers.
FEM. *Cal.* Strobiles with a two-flowered ſcale. *Cor.* none. *Piſt.* one. *Nut* with a membranaceous wing.

SPECIES.

* *With two or more leaves from the ſame ſheathing baſe.* Pine.

DESCRIPTIONS, *&c.*

1. The Wild Pine is called in Britain the Scotch Fir, from its growing naturally in the mountains of Scotland; but it is common in moſt parts of Europe, particularly the northern parts; and Monſ. Duhamel mentions his having received cones of this tree from St. Domingo. The wood is the red or yellow deal, which is the moſt durable of any of the kinds yet known. The leaves are much ſhorter than thoſe of the Pinaſter and Stone Pine, broader, of a grayiſh colour and twiſted. The cones are ſmall, pyramidal, and end in narrow points; they are of a light colour, and the ſeeds are ſmall.

[In a favourable ſoil this tree grows to the height of fourſcore feet, with a ſtraight trunk. The bark is of a browniſh colour and full of crevices. The leaves iſſue from a white truncated little ſheath in pairs; they are linear, acuminate, quite entire, ſtriated, convex on one ſide, flat on the other, mucronate, bright green, ſmooth, from an inch and half to two inches or a little more in length. The ſcales of the male catkins roll back at top, and are feathered. The inner and upper ſcales of the cones gradually terminate in a ſhort awn, but the lower ſcales have none; the ſcales open very readily *.

Few trees have been applied to more uſes than this. The talleſt and ſtraighteſt afford maſts to our navy. The timber is reſinous, durable, and applicable to numberleſs domeſtic purpoſes. From the trunk and branches of this and others of the genus tar and pitch are obtained: by inciſion barras, burgundy pitch and turpentine are acquired and prepared. The reſinous roots are dug out of the ground in many parts of the Highlands of Scotland, and being divided into ſmall ſplinters, are uſed by the inhabitants inſtead of candles. The fiſhermen make ropes of the inner bark: but hard neceſſity has taught the Laplanders and Kamſchatdales to convert it into bread. To effect this, in ſpring they ſtrip off the outer bark carefully from the faireſt trees, and collect the ſoft white ſucculent interior bark, and dry it in the ſhade. When they have occaſion to uſe it, they firſt toaſt it at the fire, then grind, and after ſteeping the flour in warm water to take off the reſinous taſte, they make it into thin cakes and bake them. Linneus remarks, that this bark-bread will fatten ſwine; and that the boys in Sweden, frequently peel off the bark in the ſpring, and eat it raw with a greedy appetite.

From the cones a diuretic oil is prepared, like oil of turpentine, and a reſinous extract, which has ſimilar virtues with Balſam of Peru. An infuſion of the buds is highly commended as an antiſcorbutic.

* Pollich.

The

The farina of the male flowers is ſometimes in ſpring, carried away by the winds in ſuch quantities, as to alarm the ignorant with the notion of its raining brimſtone [1].

Though the different ſpecies of Fir poſſeſs in common the ſame medicinal properties, and agree in affording the different products of the turpentine kind, yet ſome produce them in greater purity or abundance than others. This tree not only furniſhes moſt abundantly the *Pix liquida* or Tar; but common Turpentine, and the white and yellow reſins may alſo be obtained from it.

The manner in which Tar is procured, is by cutting the tree into pieces, which are incloſed in a large oven; with a channel at the bottom. A ſufficient degree of heat is then applied, by which the Tar is forced out of the wood, and runs off by the channel: a proceſs termed *diſtillatio per deſcenſum*.

Tar is properly an empyreumatic oil of turpentine, and has been much uſed as a medicine both internally and externally. Tar water, or water impregnated with the more ſoluble parts of Tar has been a very popular remedy in various obſtinate diſorders, both acute and chronic: and though its medicinal efficacy has been greatly exaggerated, yet Dr. Cullen acknowledges that he experienced it to be a valuable medicine, and that it appeared to ſtrengthen the tone of the ſtomach, to excite appetite, promote digeſtion, and cure all ſymptoms of dyſpepſia: at the ſame time it manifeſtly promotes the excretions, particularly that of urine.

The proportions that have been commonly employed, are two pounds of tar to a gallon of water; theſe are well ſtirred together, ſuffered to ſettle for two days, and then poured off. From a pint to a quart, according to circumſtances, may be taken in the courſe of twenty-four hours. Dr. Cullen thinks with Mr. Reid, that the acid principle gives the virtue to Tar water; and hence the Biſhop of Cloyne properly preferred the Norway Tar to that of New England, the former containing more acid than the latter.

An ointment of Tar is directed both in the London and Edinburgh Pharmacopœias, which has been chiefly employed in cutaneous diſorders [2].]

β. Tartarian Pine has a great reſemblance to the Scotch Pine, but the leaves are broader, ſhorter, and their points are more obtuſe; they emit a ſtrong balſamic odour when bruiſed: the cones of this are very ſmall, as are alſo the ſeeds, ſome of which are black, and others white.

It grows naturally in Tartary, whence Mr. Miller received the ſeeds.

γ. This has very narrow green leaves, which grow ſometimes by pairs, ſometimes by threes from the ſame ſheath; they generally ſtand erect; the cones are of a middling ſize and pyramidal; the ſcales are flat, having each a ſmall obtuſe riſing, but very compact till they are opened by the warmth of the ſun the ſecond ſpring. The ſeeds of this are much leſs than thoſe of the Pinaſter, but larger than thoſe of the Scotch Pine.

Native of the Swiſs mountains, where it is called Torch Pine, grows to a great height, is full of reſin, the wood, when firſt cut, of a reddiſh colour, and uſed in building.

[Monſ. Villars ſays it is the moſt common ſort on the mountains of Dauphiné, but that the ſhortneſs of the trunk and other characters diſappears when it grows in lower ſituations, inſomuch that it cannot then be diſtinguiſhed from the common ſort.]

ε. This has ſmooth leaves; the cones are very long and ſlender; and the ſeeds are about the ſame ſize with thoſe of the Pinaſter.—It grows in the maritime parts of Italy and the South of France.

ζ. The Pinaſter grows to a large ſize; the branches extend on every ſide to a conſiderable diſtance, and whilſt the trees are young, they are fully furniſhed with leaves, eſpecially when they are not ſo cloſe as to exclude the air from thoſe within; but as they advance in age, the branches appear naked, and all thoſe which are ſituated below become unſightly: hence, and becauſe the timber of the Scotch Pine is much preferable to this, it has been more generally propagated. The branches of the Pinaſter grow at a wider diſtance than thoſe of the Scotch Pine, and are more horizontal; the leaves are much larger, thicker and longer, grow ſtraight, have a broad ſurface on their inſide, which has a furrow or channel running longitudinally; they are of a darker green and their points are obtuſe. The cones are ſeven or eight inches long, pyramidal with pointed ſcales; the ſeeds are oblong, a little flatted on their ſides, and have narrower wings on their tops.

It grows naturally in the mountains of Italy and the South of France, where there are foreſts of theſe trees, which if ſuffered to ſtand, grow to a large ſize; in Switzerland they are frequently cut into ſhingles for covering their houſes, and alſo for making Pitch: in the South of France the young trees are cut for ſtakes to ſupport their vines.

[It was cultivated here in 1596, by Gerarde [3].]

3. This never riſes to any great height, and is the leaſt eſteemed in the country of all the ſorts. While the trees are young they make a pretty good appearance, but when they get to the height of ſeven or eight feet they become ragged and unſightly, and are therefore not worth cultivating here.

It grows naturally in moſt parts of North America; [and was cultivated in 1748, by Mr. Miller.

4. Native of North America. Cultivated in 1756, by Hugh Duke of Northumberland [4].]

5. This tree branches out on every ſide near the root; the branches at firſt grow horizontally, but turn their ends upwards; their bark is ſmooth and of a dark gray colour. The leaves are long and very narrow, of a dark green, and if they are bruiſed emit a ſtrong reſinous odour. The cones come out from the ſide of the branches; they are not much more than half the length of thoſe of the Pinaſter, but are full as large at their baſe; the ſcales are flatted, and the point of the cones is obtuſe. The ſeeds are much leſs than thoſe of the Pinaſter, but of the ſame ſhape.

It grows naturally near Aleppo, and in ſeveral other parts of Syria, and is a tree of middling growth there; but in England moſt of the trees were killed in the ſevere winter of 1740. The two largeſt which Mr. Miller had ſeen were at Goodwood in Suſſex, the ſeat of his grace the Duke of Richmond, which were raiſed by Mr. Miller, and had been tranſplanted thither the year before, and having ſcarcely recovered their removal, had made no ſhoots that ſummer, and therefore eſcaped much better than thoſe trees which were in greater vigour.

The ſeeds of this tree were ſent to Mr. Miller from Aleppo, by Conſul Cox, in the year 1732. He raiſed many of the plants in the Cheſſea garden, ſome of which were grown upwards of eight feet high by the year 1740, when moſt of them were deſtroyed by the froſt.

Mr. Miller mentions that he received cones of a Pine Tree, brought from Aleppo by Dr. Ruſſel, from which he raiſed many plants, bearing a near reſemblance to this; but that the cones were more pointed, and the ſcaly protuberances ſharper than thoſe of the Goodwood cones. Mr. Miller therefore ſuſpects them to be different, and imagines the cones brought over by Dr. Ruſſel to belong to Tourneſort's Pinus orientalis foliis curioribus amaris, fructu parvo peracuto. *Coroll.* 41 [5].

6. The leaves of the Stone Pine are not quite ſo long as thoſe of the Pinaſter, and are of a grayiſh or ſea-green colour. The cones are not more than five inches long, but are very thick, roundiſh, and end obtuſely; the ſcales are flat, and the ſeeds are more than twice the ſize of thoſe of the Pinaſter. The kernels are frequently ſerved up in deſerts during the winter ſeaſon in Italy and the South of France; and formerly they were uſed in medicine here; but Piſtachia nuts have been generally ſubſtituted for them. The wood is white, and not being ſo full of reſin as many of the

[1] Lightfoot. [2] Woodville. [3] Hort. Kew. [4] Idem. [5] Mill. Dr.

other ſorts, this tree is not cultivated for timber, but chiefly for the beauty of its leaves, and for the nuts; [the kernels of which are as ſweet as Almonds, but with a ſlight flavour of turpentine.

The Stone Pine will grow to a conſiderable height, with a ſtraight and fair ſtem, but a rough bark. The leaves contribute to diverſify the ſcene in plantations, as they differ in colour from the other ſorts, and are arranged in a different manner. The cones are very large and turbinate, ſtriking the eye by their bold appearance when hanging on the trees; and when cloſely examined, they afford pleaſure from the beautiful arrangement of their ſcales [1].

Native of the South of Europe.] Very common in Italy (particularly about Ravenna:) but Mr. Miller doubts whether this ſpecies is originally of that country, becauſe there are none of the trees growing there, except where they have been planted, or where the ſeeds are ſcattered from planted trees. He has frequently received the ſeeds of a Pine from China ſo like thoſe of this ſort as not to be diſtinguiſhed from them; but having never vegetated, he could not aſcertain the ſpecies.

[Sir George Staunton relates that the kernels of the Stone Pine are much reliſhed by the Chineſe.

It was cultivated here in 1570, as appears from Lobel [m].]

7. This has very long narrow leaves, growing by threes out of each ſheath. The cones are as large as thoſe of the Stone Pine, but they are more pointed, and the ſcales are looſer; they open horizontally and diſcharge the ſeeds. The French in Canada built a ſixty-four gun ſhip entirely with the wood of this tree, which is like that of the Scotch Pine, but has more reſin.

It is a native of North America, whence it was ſent to Mr. Ball of Exeter, and to Compton Biſhop of London, by the name of Frankincenſe Pine.

β. Leaves long, generally three in each ſheath. Cones in cluſters round the branches, as long as thoſe of the Pinaſter, but with rigid ſcales: the ſeeds alſo are nearly as large as thoſe of the Pinaſter. It grows naturally in Virginia, and other parts of North America, where it riſes to a great height. There are many of theſe trees in the noble plantations of his Grace the Duke of Bedford at Woburn, which were twenty feet high, when they were not of many years ſtanding, and kept pace with the other ſorts in the ſame plantation.

[According to the Kew catalogue, *Pinus Tæda* was introduced in 1736, by Peter Collinſon, Eſq.—There are many other varieties ſent over from North America, ſome of which have little or no difference.]

8. This tree grows to the height of twenty-five or thirty feet, on the ſwamps of North America. The leaves are a foot or more in length, growing in tufts at the ends of the branches, and therefore having a ſingular appearance. The wood is of little uſe but for fuel.

[Native of Carolina and Georgia. Cultivated here in 1730 [n].]

9. The Siberian Stone Pine is confounded with that of Switzerland; but the cones of the latter are ſhort and roundiſh, with cloſe ſcales, whereas thoſe of the Siberian Pine are long and the ſcales looſer. The leaves have a near reſemblance; but the plants raiſed from Swiſs ſeeds make much greater progreſs than the others, which can ſcarcely be kept alive in England.

[The Cembra Pine grows higher up the Alps than any other Pine, and is even found at elevations where the Larch will not grow. The ſtones are ſhorter than thoſe of the Stone Pine, but full as thick. The wood is very ſoft, and having ſcarcely any grain, is very fit for the carver. The peaſants of the Tyrol, where this tree abounds, make various ſorts of carved works with this wood, which they diſpoſe of in Switzerland among the common people, who are fond of the reſinous ſmell which it exhales.

Linnæus and other botaniſts make this the ſame with the Siberian Stone Pine, which reſembles it much, but Duhamel and Haller will have them to be diſtinct ſpecies. The Siberian Pine is lofty and ſtraight, puſhing out few ſide branches; whereas the Swiſs Pine is ſmall, knotty and often deformed. The wood of the Siberian has *no* ſmell, and the cones are different. In the Brianconnois the Cembra is called *Alviez*, and in Savoy *Aroles* [o]. But Villars remarks that it has different names in almoſt every village of Dauphiné. The kernels are good to eat, and yield abundance of oil which ſmells a little of turpentine; it is pectoral and diuretic [p].

Mr. Harte deſcribes it under the name of *Aphernonſii* Pine: and at Gleddow near Leeds it is called the *Gleddow* Pine. There are ſeveral of the trees in the plantations belonging to Jeremiah Dixon, Eſq. at that place.

It is likely to thrive in bleak rocky ſituations, or peaty moors: the timber is large; the bark of the trunk is of a whitiſh caſt. Wainſcotting, flooring and other joiner's work made of the planks, are of a finer grain, and more beautifully variegated than Deal, and the ſmell is more agreeable. A white odoriferous reſin is extracted from this wood [q].

Scopoli thus deſcribes the Cembra in his Iter Tyrolenſe—Bark ſmooth. Leaves from three to five in a ſheath, three-cornered, the corners rough when ſtroaked downwards; one of them flat, ſhining and green; the others whiter and not ſhining. Male aments in pairs, half an inch long, red, coming out at the baſe of the new leaves, compoſed of keeled, ovate ſcales, and two-celled, pedicelled anthers. Female cones oval, compoſed of hemiſpherical ſcales terminated by a brown point, wrinkled, of a pale ferruginous colour, two-celled within, and having a brown wedge-ſhaped nut in each cell, furniſhed with two oppoſite angles, and containing an eatable, oily, white kernel, covered with a ruſous ſkin.

Native of Switzerland and Siberia. Cultivated in 1746, by Archibald Duke of Argyle [r].

10. Native of Hiſpaniola. This has been confounded with Pinus Strobus or the Weymouth Pine [s].

11. The Weymouth Pine, or White Pine as it is called in North America, is one of the talleſt ſpecies, often attaining a hundred feet in height in its native country. The bark is very ſmooth and delicate, eſpecially whilſt the tree is young. The leaves are long and ſlender; they are pretty cloſely placed on the branches, and make a fine appearance. The cones are long, ſlender and very looſe, opening with the firſt warmth of the ſpring; ſo that if the ſeeds are not gathered in winter, the ſcales open and let them out. The wood is eſteemed for maſts of ſhips; and there was a law made in the ninth of Queen Anne for the preſervation of theſe trees, and to encourage their growth in America. It is only within forty years paſt that they began to be propagated in England in any plenty [t]; though there were ſome large ones growing in two or three places long before, particularly at Lord Weymouth's, and at Sir Wyndham Knatchbull's in Kent: and it has been chiefly from the ſeeds of the latter, that moſt of the trees now in England have been raiſed, or from thoſe in the plantations of the Duke of Argyle at Whitton. This and the Scotch Pine are the beſt worth cultivating for timber. In England it is called Lord Weymouth's or New-England Pine: [and was cultivated in 1705, by the Dutcheſs of Beaufort [u].

The value of the timber in our iſland, eſpecially in cold ſoils, is perhaps doubtful; nor will it bear the ſeverity of our winters, and the variableneſs of our ſprings, except in particular ſituations and ſoils; as Earl Nugent's plantations at Gosfield and others too plainly teſtify [w].

The ſize to which this beautiful ſpecies will arrive may be ſuppoſed from a tree which was cut down in 1736 on the banks of the river Merimack, that was ſeven feet eight inches in diameter at the butt end [x]. It is very fit for maſts.

12. That noble tree, the Cedar of Lebanon, has a general ſtriking character of growth ſo peculiar to itſelf, that no other tree can poſſibly be miſtaken for it. It is placed by Linneus, along with the Larch, in the ſame genus with the Firs and Pines: it agrees with the former in its foliation, with the latter in being evergreen.

The ſturdy arms, ſays Evelyn, grow in time ſo weighty, as often to bend the very ſtem and main ſhaft; the leaves much reſemble thoſe of the Larch, but are ſomewhat longer and cloſer ſet, erect and perpetually green, which thoſe of the Larch are not; but hanging down, dropping off, and deſerting the tree in winter. The cones are tacked and ranged between the branch-leaves, in ſuch order, as nothing appears more curious and artificial, and at a little diſtance exceedingly beautiful: theſe cones have the baſes rounder, ſhorter, or rather thicker, and with blunter points, the whole circumzoned, as it were, with pretty broad thick ſcales, which adhere together in exact ſeries to the very ſummit, where they are ſomewhat ſmaller; but the entire lorication ſmoother couched than thoſe of the Firs: within theſe repoſitories, under the ſcales, neſtle the ſmall nutting ſeeds, of a pear-ſhape [a].] Theſe cones grow upon the upper part of the branches, and ſtand erect, having a ſtrong, woody, central ſtyle, by which they are firmly annexed to the branch, ſo as with difficulty to be taken off; which central ſtyle remains upon the branch after the cone is fallen to pieces; for it never drops off whole, as thoſe of the Pines do.

Many wonderful properties are aſcribed to the wood of this celebrated tree, ſuch as its reſiſting putrefaction, deſtroying noxious inſects, continuing a thouſand or two thouſand years ſound, yielding an oil famous for preſerving books and writings, [purifying the air by its effluvia, inſpiring worſhippers with a ſolemn awe, when uſed in wainſcotting churches or chapels, &c.

Touching the duſturnity of this material, ſays Mr. Evelyn, 'tis recorded, that in the temple of Apollo Utica, there was found timber of two thouſand years old; and at Saguntì in Spain, a beam in an oratory conſecrated to Diana, which was brought to Zant, two centuries before the deſtruction of Troy: that Seſoſtris built a veſſel of Cedar of 280 cubits: and the ſtatue of the Goddeſs in the famous Epheſine temple, was ſaid to be of this material, as was moſt of the timber-work of that glorious ſtructure. In the relation of the properties aſſigned to this tree there is much vulgar error, and confuſion of the Cedar of Lebanon, with other trees called Cedars; and as to the materials uſed in the heathen temples, it is very uncertain what they were. We have better authority than that of Pliny, that this was the ſpecies of timber employed in building the ſumptuous temple and palace of Solomon at Jeruſalem.—" Now therefore command thou, ſaid " Solomon to Hiram, that they hew me Cedar-trees " out of Lebanon. I will do all thy deſire, replied " Hiram concerning timber of Cedar, and concerning " timber of Fir [b]. And Solomon raiſed a levy of " thirty thouſand men out of all Iſrael; and he ſent " them to Lebanon, ten thouſand a month, by courſes: " and he had threeſcore and ten thouſand that bare " burdens, and fourſcore thouſand hewers in the moun- " tains [c]. And he covered the temple with beams and " boards of Cedar. And he built chambers againſt " it, which reſted on the houſe with timber of Cedar [d]. " And the Cedar of the houſe within was carved with " knops and open flowers: all was Cedar, there was " no ſtone ſeen [e]. And he built the inner court with " three rows of hewed ſtone, and a row of Cedar " beams [f].—Solomon's houſe alſo of the foreſt of " Lebanon was covered with Cedar upon the beams: " and the porch of judgment was covered with Cedar " from one ſide of the floor to the other. And the " great court of his palace was with three rows of " hewed ſtones, and a row of Cedar beams [g]."

Mr. Evelyn remarks, that the Cedar is of ſo dry a nature, that it does not well endure to be faſtened with nails, from which it uſually ſhrinks, and therefore pins of the ſame wood are better [h].

The alluſion of the Pſalmiſt, of ſpreading abroad like a Cedar in Libanus, ſhows that he was well acquainted with this tree, which is remarkable for the wide ſpread of its branches, rather than for its height. Had Milton known it as well, he would not have uſed the expreſſion of the—

" Inſuperable height of loftieſt ſhade:"

in ſpeaking of the Cedar.

It is not only found on mount Lebanon or Libanus, but Belon obſerved it on the mountains Amanus and Taurus.

Solomon's fourſcore thouſand hewers muſt have conſiderably thinned the foreſt of Libanus. Few now remain there.

Rauwolff in 1575 ſaw only twenty-four ſound trees, and two old decayed ones. " We found ourſelves (ſays he) upon the higheſt point of the mountain, and ſaw nothing higher, but only a ſmall hill before us, all covered over with ſnow, at the bottom whereof the high Cedar trees were ſtanding. And though this hill hath in former ages been quite covered over with Cedars, yet they are ſince ſo decreaſed, that I could tell no more but twenty-four that ſtood round about in a circle, and two others, the branches whereof are quite decayed for age. I alſo went about in this place to look out for ſome young ones, but could find none at all. Theſe trees are green all the year long, have ſtrong ſtems that are ſeveral fathoms about, and are as high as our Fir trees [i]."

Maundrell, in 1696, may 9th, could reckon only ſixteen large trees, but many ſmall ones. His account is as follows.—" Having gone for three hours acroſs the plain of Tripoli, I arrived at the foot of Libanus; and from thence continually aſcending, not without great fatigue, came in four hours and a half to a ſmall village called Eden, and in two hours and a half more to the Cedars. Theſe noble trees grow amongſt the ſnow near the higheſt part of Libanus; and are remarkable as well for their own age and largeneſs, as for thoſe frequent alluſions made to them in the word of God. Here are ſome of them very old, and of a prodigious bulk; and others younger, of a ſmaller ſize. Of the former I could reckon up only ſixteen; and the latter are very numerous. I meaſured one of the largeſt, and found it twelve yards ſix inches in girt, and yet ſound, and thirty-ſeven yards in the ſpread of its boughs. At about five or ſix yards from the ground, it was divided into five limbs, each of which was equal to a great tree [k]."] What Maundrell has related, ſays Mr. Miller, was confirmed to me by a worthy gentleman of my acquaintance, who was there in the year 1720, with this difference only, that in meaſuring the branches of the largeſt tree, he found them to be twenty-two yards in diameter. [Suppoſing theſe two gentlemen to have meaſured the ſame tree, and not to be miſtaken in their admeaſurement, this difference can only be reconciled by ſuppoſing that the latter meant the ſpread of the boughs from the trunk, the former the whole ſpread or diameter, which we may conceive to have increaſed in twenty-four years.] The traveller Le Bruyn reckons about thirty-five or thirty-ſix trees remaining on mount Libanus when he was there, and would perſuade us it was not eaſy to reckon their number, as is reported of the ſtones of our Stonehenge on Salisbury plain. He alſo ſays that ſome of the cones grow dependent, which is abundantly confuted by the above-mentioned travellers, and alſo from our own experience.

[The few Cedars ſtill remaining on mount Libanus are preſerved with a religious ſtrictneſs. On the day of the Transfiguration, the Patriarch repairs in proceſſion to theſe trees, and celebrates a feſtival called the feaſt of Cedars [l].

We have now probably more Cedars in England, than are left on mount Libanus.] It is matter of

ſurpriſe

ſurpriſe to me, ſays Mr. Miller, that this tree has not been more cultivated in England formerly, for till within a few years paſt, there were but few here; ſince it would be a great ornament to barren bleak mountains, where few other trees will grow ſo well; it being a native of the coldeſt parts of mount Libanus, where the ſnow continues great part of the year. From the obſervations I have made of the trees now growing in England, I find that ſuch as have been planted in a ſtrong, rich, loamy earth, have made a poor progreſs, in compariſon with thoſe which have grown upon a ſtony meagre ſoil. That theſe trees are of quick growth, is evident from four of them in the botanic garden at Chelſea, which, as I have been credibly informed, were planted there in the year 1683, and at that time were not above three feet high. [Sir Hans Sloane, in a letter to Mr. Ray, dated march 7, 1684-5, ſays—" I was the other day at Chelſea, and find that the artifices uſed by Mr. Watts have been very effectual for the preſervation of his plants, inſomuch that this ſevere enough winter has ſcarce killed any of his fine plants. One thing I much wonder, to ſee that the *Cedrus Montis Libani*, the inhabitant of a very different climate, ſhould thrive here ſo well, as without pot or greenhouſe to be able to propagate itſelf by layers this ſpring. Seeds ſown laſt autumn have as yet thriven very well, and are like to hold out. The main artifice I uſed to them, has been to keep them from the winds, which ſeem to give a great additional force to the cold, in deſtroying tender plants[1]."] Two of theſe trees were in 1766 upwards of twelve feet and a half in girt, at two feet above the ground, and their branches extended more than twenty feet on every ſide their trunks; which branches, though they were produced twelve or fourteen feet above the ſurface, did at every termination hang very near the ground, and thereby afford a goodly ſhade in the hotteſt ſeaſon of the year. [In auguſt, 1793, the girt of the largeſt at three feet from the ground was twelve feet eleven inches and a half, of the ſmaller twelve feet and a quarter of an inch, as meaſured by Sir *Joſ.* Banks.]

The ſoil in which theſe trees were planted, is a lean hungry ſand mixed with gravel, the ſurface of which is ſcarcely two feet deep, before a hard rocky gravel appears. They ſtood at four corners of a pond, bricked up within two feet of their trunks, ſo that their roots having no room to ſpread on one ſide were cramped in their growth; but whether their ſtanding ſo near the water might not have been advantageous to them, I cannot ſay; but ſure I am, if their roots had had full ſcope in the ground, they would have made a greater progreſs. [Probably the roots, finding themſelves ſtopped by the brick wall, tended downwards, and ſpread themſelves in the moiſt earth under the water, which promoted greatly the growth of the trees; for ſome years after the time of which Mr. Miller ſpeaks, this pond having been filled up, theſe noble trees decayed, and were quickly ruined for want of their accuſtomed beverage.]

I have alſo obſerved, that lopping or cutting theſe trees is very injurious to them, more perhaps than to any other of the reſinous trees, in retarding their growth: for two of the four trees abovementioned, having been unadviſedly planted near a green-houſe, when they began to grow large, had their branches lopped, to let the ſun into the houſe, whereby they were ſo much checked, as to be little more than half the ſize of the other two.

All theſe trees produced, for ſeveral years, large quantities of catkins, or male flowers; but only three of them had, in 1766, produced cones; nor was it above thirty-five years before that period, that theſe ripened their cones, ſo as to perfect the ſeeds; but after that, the ſeeds that fell out of the cones on the ground near them produced plants in plenty, which came up naturally without care. Since then we find that the Cedar is ſo far naturalized to our country as to produce ripe ſeeds, we need not fear a ſupply, without depending on the cones from the Levant: but I find they are more apt to produce and ripen their cones in hard winters than in mild ones; which is a plain indication that they will ſucceed, even in the coldeſt parts of Scotland, where, as well as in England, they might be propagated to great advantage.

[The Cedars at Chelſea are ſuppoſed, in the Kew catalogue, to have been the firſt known to be planted in England. Dr. Hunter, in his additions to Evelyn ſays, that we do not know when and by whom the Cedar was firſt introduced here. Dr. Turner, when he treats of the Pine tree, and other trees of that kind, ſays nothing of it. Gerarde mentions it not as growing here; and Parkinſon ſays, the branches, ſome ſay, all grow upright, but others, ſtraight out. It is very certain, from what Mr. Evelyn ſays, that it was not cultivated in England in 1664, but from the warm manner in which he expreſſes himſelf on this head it is probable, that it ſoon after became an object of the planter's attention.—Mr. Evelyn informs us, that he received cones and ſeeds of the few remaining trees on Libanus; and adds, why they ſhould not thrive in old England I know not, ſave for want of induſtry and trial[a].

The old palace or manor houſe at Enfield, was occupied by Robert Uvedale, L.L.D. who kept a flouriſhing ſchool there, about the year 1670. In the gardens, among other curious trees planted by Dr. Uvedale, there is a fine Cedar. The body, excluſive of the boughs, contains about 103 cubical feet. Girt at top three feet ſeven inches, ſecond girt ſeven feet nine inches, third girt four feet, fourth, fourteen feet ſix inches. It is in height forty-five feet nine inches, eight feet having been broken off from its top by the hurricane in 1703; and in 1793, was twelve feet in girt, at three feet from the ground. An account of it was printed in 1788, in four pages ſmall folio[b].

Several other Cedars of conſiderable ſize are or were ſcattered about in different parts of this kingdom: ſome of the fineſt of theſe were planted at Whitton by Archibald Duke of Argyle. One of the moſt remarkable was blown down by the hurricane that happened on the firſt of january 1779. It grew on the north ſide of Hendon place in Middleſex. Its height was ſeventy feet, the diameter of the horizontal extent of the branches was one hundred feet, the circumference of the trunk ſeven feet above the ground ſixteen feet; and at twelve feet above the ground twenty-one feet. At this latter height it began to branch; and its limbs, about ten in number, were from ſix to twelve feet in circumference. This tree is ſuppoſed to have been two hundred years old, and tradition ſays was planted by Queen Elizabeth herſelf[c]. Tradition is ſeldom to be depended on, and Queen Elizabeth is a great favourite with tradition-mongers. But is it probable if ſuch a tree exiſted in 1579, that Gerarde, Parkinſon and Evelyn ſhould know nothing of it? When blown down it was perfectly ſound, and ſeemed as if not grown to maturity; it is probable therefore that it was not two hundred years old, for the Cedars at Chelſea attained ther full ſize and decayed in leſs than a century.

The following are the dimenſions of a fine Cedar growing at Hillington near Uxbridge. The height fifty-three feet; the extent of the branches from eaſt to weſt ninety-ſix, from north to ſouth eighty-nine feet; the circumference of the trunk cloſe to the ground thirteen feet and a half, ſeven feet above the ground twelve and a half, twelve feet above the ground fourteen feet eight inches, at the height of thirteen feet and a half juſt under the branches fifteen feet eight inches. It has two principal branches, one of which is forked eighteen inches above its origin: before it divides it meaſures twelve feet round, after its diviſion one of the forks meaſures eight feet and a half, the other ſeven feet ten inches. The other primary branch, at its origin, meaſures ten feet, and ſoon dividing, throws out two ſecondary ones, each five feet and a half. Its age is ſuppoſed to be 116 years[d].

[c] Hunter's additions to Evelyn. [d] Idem.

The

The only relick of Dr. James Sherard's famous botanic garden at Eltham, ſo elegantly diſplayed by Dillenius, is a Cedar of Lebanon, which girts nine feet at three feet from the ground. It is now in the poſſeſſion of John Dorington, Eſq.[9]

Another of theſe trees is in the fellow's garden at Emanuel College in Cambridge, on a lawn by the ſide of the pond. It was planted in the year 1730 by Profeſſor John Martyn, then a member of that college. The leading ſhoot being killed by the ſevere winter of 1740, its height is not very conſiderable; in form it is pyramidal, like the Spruce Fir, and it branches almoſt from the bottom.

Mortimer, in his Art of Huſbandry, (edit. 2. 1708. p. 370.) affirms, that he had raiſed ſeveral Cedars of cones which he had from Lebanon, and that he then had a walk planted with them.]

13. There is a particular ſort of this tree, brought from North America, and growing in the garden of Mr. Peter Collinſon at Peckham in Surry, which differs from the European ſort in having darker ſhoots. This is not mentioned by botaniſts, nor has it been long known in Europe, though it grows plentifully in ſome of the northern parts of America. It does not promiſe to make ſo large trees as the European, and therefore ſhould be planted with thoſe of lower growth, to make a variety. It will endure the ſevereſt cold of this climate[1].

14. The common or white Larch Tree is of quick growth, and will riſe to the height of fifty feet; the branches are ſlender, and their ends generally hang down. The leaves are long and narrow, in cluſters from one point, ſpreading open above like the hairs of a painter's bruſh, of a light green, and falling off in autumn; in which circumſtance this and the preceding differ from all the other ſpecies of this genus. In the month of april the male flowers appear, diſpoſed in form of ſmall cones; the female flowers are collected into egg-ſhaped obtuſe cones, which in ſome have bright purple tops, but in others they are white: this difference is accidental, for ſeeds taken from either will produce plants of both ſorts: the cones are about an inch long, and the ſcales are ſmooth; under each ſcale two winged ſeeds are generally lodged.

There are two other varieties of this tree, one a native of America, the other of Siberia: the latter requires a colder climate than England, for the trees are apt to die in ſummer here, eſpecially if they are planted on a dry ſoil. The cones of this which have been brought to England, ſeem to be in general larger than thoſe of the common ſort; but there is ſo little difference between the trees in their characteriſtic notes, that they cannot be diſtinguiſhed as different ſpecies, though in the growth of the trees there is a remarkable difference.

Mr. Miller mentions another variety from China, which he diſtinguiſhes as a ſpecies, under the name of *Larix chinenſis*. The cones were ſent to Hugh Duke of Northumberland, and the ſeeds, being ſown, grew both at Stanwick and in the Chelſea garden. The cones were much larger than thoſe of the common ſort, and ended in acute points; the ſcales were prominent like thoſe of the Scotch Pine, and had ſo little reſemblance to thoſe of the Larch, that every one who ſaw them, imagined they belonged to a ſort of Pine, and they were ſent over under the name of Pine good to keep up banks. As the plants made but little progreſs the firſt year, they were weak, and caſting off their leaves in autumn were ſuppoſed to be dead, and thus moſt of them were loſt; but thoſe which eſcaped, afterwards ſhot out their branches horizontally, ſpreading cloſe to the ground, and ſeemed to be ſhrubs, which would never riſe upright. They are ſo hardy, as to thrive in the open air without any protection.

[Pallas thus diſtinguiſhes the European Larch from the American. In the latter the branches are more ſlender, with a bark more inclining to yellow, and the ſcars more ſlender and cluſtered; the leaves are more tender, narrower, more glaucous, and the outer ones in each bundle ſhorter; cones only one-third of the ſize, blunt, with ſcales ſcarcely exceeding twelve in number, thinner, more ſhining, retuſe-emarginate; wings of the ſeeds ſtraight, more oblong, narrower, and together with the ſeed itſelf of a more diluted gray colour.

In the European *Larch* the bark of the branches is of an aſh-coloured gray; the leaves a little wider, bright green, all nearly equal, commonly more than forty in a bundle: the cones an inch long, with above thirty woody, ſtriated, rounded, entire ſcales. Seeds brownish-gray, with ſubtriangular wings ſomewhat bent in. In both, the cones are bent upwards on very ſhort pedicles[2].

No tree is more valuable, or better deſerves our attention in planting than the Larch. It is a native of the South of Europe and of Siberia. It appears from Parkinſon's Paradiſus that it was cultivated here in 1629[3]; and Evelyn ſays, a tree of good ſtature, not long ſince to be ſeen about Chelmsford in Eſſex, ſufficiently reproaches our not cultivating ſo uſeful a material for many purpoſes, where laſting and ſubſtantial timber is required. We read of beams of no leſs than 120 feet in length, made out of this goodly tree. There is abundance of this Larch timber in the buildings at Venice, eſpecially about the palaces in Piazza San Marco, where Scamozzi ſays he uſed much of it, and infinitely commends it. Nor did they only uſe it in houſes, but in naval architecture alſo. It ſeems to excel for beams, doors, windows, and maſts of ſhips: it reſiſts the worm; being driven into the ground it is almoſt petrified, and will ſupport an incredible weight: it bears poliſhing excellently well, and the turners abroad much deſire it: the Larch makes everlaſting ſpouts, pent-houſes and featheredge, which needs neither pitch or painting to preſerve them: excellent pales, poſts, rails, props for vines, &c to theſe add the palats, on which painters ſeparate and blend their colours; and were the tables on which the great Raphael and moſt famous artiſts eternized their ſkill[4].]

In Switzerland, where theſe trees abound, and they have a ſcarcity of other wood, they build moſt of their houſes with it; and great part of their furniture is alſo made of the wood, ſome of which is white, and ſome red, but the latter is moſt eſteemed. The redneſs of the wood is by ſome ſuppoſed to be from the age of the trees, and not from any difference between them, but is rather owing to the quantity of turpentine contained in them. They frequently cut out the boards into ſhingles of a foot ſquare, with which they cover their houſes, inſtead of tiles or other covering: theſe are at firſt very white, but after they have been two or three years expoſed, become as black as charcoal, and all the joints are ſtopped by the reſin, which the ſun draws out from the pores of the wood, which is hardened by the air, and becomes a ſmooth ſhining varniſh, which renders the houſes ſo covered impenetrable to either wind or rain; but as this is very combuſtible, the magiſtrates have made an order of police, that the houſes ſo covered ſhould be built at a diſtance from each other to prevent fire, which has often done great damage in villages.

In moſt countries where this wood is in plenty, it is preferred to all the kinds of Fir for every purpoſe; and in many places there are ſhips built of this wood, which they ſay are durable; therefore this may be a very proper tree for planting upon ſome of the cold barren hills in many parts of England, which at preſent produce nothing to their proprietors, and in one age may be large eſtates to their poſterity, and a national advantage; which might be effected without a great expenſe, where the buſineſs is properly conducted.

[Line of battle ſhips are built with Larch at Archangel, which generally laſt fifteen years. At Venice it is alſo ſometimes employed in ſhip-building, eſpecially in the lighter parts of the upper works, but not where maſſy pieces of timber are required, on account of its weight. It reſiſts the intemperature of the air more

[9] Lyſon's environs of London, 403.

[4] Sylva. p. 153.

than any wood known in that country, and therefore is much uſed for outer gates, pales, &c. In ſome of the old palaces at Venice there are beams of Larch as when firſt placed. In a word, wherever ſtrength and durability are required, this is reckoned there the moſt choice wood they have[s].

Larch wood, ſays Dr. Anderſon, is poſſeſſed of ſo many valuable qualities, that to enumerate the whole would appear extravagant hyperbole. It is known to reſiſt water without rotting almoſt for ever. The piles of this timber on which the houſes of Venice were built many hundred years ago, are ſtill found as freſh as when firſt put in. Stakes of it have been tried in the decoys of Lincolnſhire, which between wind and water, have already worn out two or three ſets of oak ſtakes, and do not yet diſcover any ſymptoms of decay. It is alſo known to poſſeſs the valuable quality of neither ſhrinking nor warping when put into work, nor is it liable to be pierced by worms in our climate.

It is known to be one of the quickeſt growing trees, remarkably hardy, and extremely beautiful. It is much more eaſily reared than the Oak, and could be ſpread over a great extent of mountains, if ſufficiently bare of herbage, at little or no expenſe, by the natural ſhedding of its ſeeds. It would be valuable not only for ſhip-plank; but even crooked timbers might be obtained, by uſing a little art to bend it when young. For flood-gates in navigable canals and wet docks it would exceed every thing that can be obtained in this climate. For barrel ſtaves it would be inimitable; and in building it would anſwer all the purpoſes to which Fir is now applied, being much ſtronger and more durable than that wood. When it is alſo adverted to, that it is next to incombuſtible, it deſerves to be ſtrongly recommended to planters in this country, particularly in the moſt rugged and barren diſtricts; where, at a very trifling charge, eſtates might be brought to a hundred times their preſent value[t].

The ſame valuable author, in the third volume of his Eſſays relating to Agriculture and Rural Affairs, has one entire long chapter, on the value and uſes of the Larch tree; in which he ſays, that it is ſo much more valuable than the Scotch Fir, that it is now univerſally preferred to it, for plantations of large extent, in almoſt every ſituation. That as it has only been of late introduced into Britain, the qualities of the wood are not ſufficiently underſtood: for before the laſt thirty years it was cultivated rather as an ornamental tree, than with a view to profit. But wherever it has been introduced it grows ſo freely; is ſo beautiful when in leaf; ſo highly ornamental when covered with its abundant pink bloſſoms in the ſpring; and is ſo elegant in its form, that it is ſure to become a favourite with the planter.

Dr. Anderſon is ſo full in his collections upon this ſubject, that I ſhall take the liberty of abſtracting ſuch parts of his memoir as have not been already given from their primary ſources.

Among the Romans the Larch was employed, in preference to every other kind of wood, in building, where ſtrength and durability were required; and Vitruvius attributes the ſudden decay of buildings erected in his time, in a great meaſure to the want of Larch in the neighbourhood of Rome; it having been exhauſted before his time, and the expenſe of bringing it from a diſtance being ſo high, as greatly to circumſcribe the uſe of it.

Dr. Pallas, in his ſurvey of the Ruſſian dominions in Aſia, obſerved ſeveral *tumuli* at Kamtſhatka reared at a period ſo remote, that none of the preſent inhabitants had any tradition reſpecting their origin. The platform was covered by Larch wood, over which the mound of earth was raiſed; and the wood was found to be uncorrupted.

I have in my garden, ſays Monſ. le Preſident de la Tour d'Aigues, in the year 1787, ſome rails, part of which are Oak, and part of them Larch wood; they were made in 1743, and only once painted. The Oak has yielded to time, but the Larch is ſtill ſound. They make caſks of it in Provence: the fineneſs of the grain retains the ſpirit of the liquor perfectly, and does not alter its qualities: it has been uſed for that purpoſe for time immemorial in the higher Dauphiné. I have in my caſtle of Tour d'Aigues beams of twenty inches ſquare, which are ſound, though upwards of two hundred years old; but trees of this ſize are now to be found only in places whence they cannot be tranſported. There are in ſome parts of Dauphiné, and in the foreſts of Baye in Provence, Larch trees, which two men could not graſp, and about ſeventy-two feet in height. This account is printed in Memoirs of the Royal Society of Agriculture, Paris 1787.

The Larch muſt ſtand to be of a ſufficient age before the timber acquire its beſt qualities of ſtrength and durability. We have not yet had an opportunity of uſing any of it in perfection in Great Britain; its introduction into this country having been at a period too late to admit of it. The two firſt trees that were planted in Britain, by the beſt accounts I can find, are at Dunkeld in Perthſhire, the ſeat of the Duke of Athole. They were planted in 1741: conſequently Dr. Anderſon ſhould have confined his remark to North Britain, for we have many trees in England prior to theſe: and ſome even in Scotland, belonging to Mr. Drummond were planted in 1734.

It appears from Parkinſon's Paradiſus, that the Larch tree was cultivated here ſo long ſince as 1629: it was then however, as he ſays, "rare, and nurſed up but "with a few, and thoſe only lovers of rarities."

The largeſt of the Larch trees on the Duke of Athole's lawn at Dunkeld was meaſured in the month of march 1796, and the following are its dimenſions:

	F.	In.		F.	In.
At the height of	1	8	from the ground, the circumference is -	11	11
	3	0	———	10	0½
	6	0	———	9	0
	9	0	———	8	6
	12	0	———	8	2
	18	0	———	7	11
	24	0	———	7	7

The whole height was eighty-five feet. There are ſeveral Larches upwards of one hundred feet in height, which are five or ſix years younger, but none of ſo great a girt. The largeſt of Mr. Drummond's was ninety-ſeven feet high, but leſs in circumference.

For a trial, the Duke of Athole has applied Larch to a variety of purpoſes, ſuch as mill-axles, flooring in houſes, window-frames and doors, poſts and rails, and boat-building: for all of which it appeared to anſwer ſo well, that it is the greateſt acquiſition of wood ever introduced into Great Britain, eſpecially as it attains a conſiderable ſize, on high grounds and bleak expoſures, where even Scotch Firs either die or become ſtinted. Fiſhing boats made of Larch under forty years growth, laſt nearly three times as long as thoſe built of Norway Fir.

The late violent winds blew down a Larch in the Duke's lawn of fifty years of age, eighty-ſix feet ſix inches in height, containing eighty-two feet of ſolid wood; for which four pounds ſterling was offered as it lay on the ground.

Dr. Anderſon has adduced a variety of ſatisfactory inſtances and experiments, from which the durability of this wood is eſtabliſhed beyond a doubt, even in the early periods of its growth. Nor is this its only good quality; for, when made into planks, there are inconteſtible proofs of its neither ſhrinking nor warping, and of its not being liable to be attacked by the worm, during the courſe of ſeveral ages.

It is not yet known whether Larch wood is capable of reſiſting the ſea-worm. Dr. Anderſon propoſes to aſcertain this, by ſinking a piece of ſound, well-ripened Larch wood, with another piece of ſound Oak wood in the river Medway at Rocheſter bridge, where it is well known that every other kind of wood is very ſoon perforated by the ſea-worm.

Larch wood is in a manner incombuſtible; that is, though it may be conſumed by fire, yet where the maſſes are large, even if a fire be placed on the bare wood, though it will be ſlowly corroded by it, yet

[s] Tranſact. ſoc. arts, vol. 6. for 1788.

[t] Report, in the preſent ſtate of the Hebrides, p. 238.

unleſs in particular circumſtances it cannot be made to flame, ſo as to communicate it to other bodies. This quality of Larch wood was known in the time of Julius Cæſar, who calls it *lignum igni impenetrabile*: and Mr. Harte obſerves, that there is perhaps no inſtance of the cottages in Carniola being ſet on fire, though they are ſo careleſs as to throw flaming firebrands on their roofs [a]. This ſeems to contradict what was ſaid above with relation to Switzerland; but I apprehend that more of the houſes in that country are built of Fir than of Larch. Duhamel however, in confirmation of Mr. Miller's opinion ſays, that the reſinous ſubſtance in Larch trees is looked upon to be very combuſtible, and therefore there is a public order in the diſtrict near Briançon, that houſes built with it ſhould never join, but ſtand at a certain diſtance [b]. Or rather Mr. Miller copied from Duhamel.

Matthiolus informs us, that unwilling as this wood may be to take fire, yet it is no-ways difficult to burn it in kilns, glaſs-houſes and furnaces belonging to iron-works, when once the inſide of theſe receptacles is rendered intenſely hot. Such is the practice in the iron-works of Stiria and the biſhopric of Trent, where this wood is of ſingular uſe, when there is heat ſufficiently fierce and ſtrong to penetrate it forcibly. On this point, ſays Mr. Harte, experience alone can lead us to adopt the true opinion.—Though I have carefully looked over this learned author's eſſays, yet I cannot find what Dr. Anderſon quotes from them, on the incombuſtibility of the Carniolian cottages.

To the other uſes of Larch wood, Mr. Harte adds, that becauſe it is not liable to be warped or to be attacked by worms, the Italians uſe it for back-boards, to place behind fine drawings, when they frame and glaſs them; as alſo for picture-frames, table-frames, &c. becauſe no other wood gives gilding ſuch force, brightneſs, and as it were a ſort of natural burniſhing; and this is the main ſecret why Italian gilding on wood is ſo greatly preferable to ours, which has often a tarniſhed ſpongy caſt, and looks like gilt gingerbread. The Italians alſo prefer it for making the wheels of poſt-chaiſes and other carriages, as being very durable and unapt to crack. No boards make better wainſcotting, or take paint better. The application of it to ſhingles for covering barns and other outhouſes would be invaluable in theſe kingdoms. The look of it would be far better than thatch; neither rains would rot it, nor winds ruffle it; and if it will not eaſily catch fire, it is a great additional recommendation. Whereas thatch is liable to all theſe accidents, and harbours ſparrows, inſects, cobwebs, duſt and all ſorts of foulneſs, to the great detriment of the grain: and though thatch be cheaper at firſt, it is dearer in the long run than tiling or ſlating. The ſhingles in the Griſons are half an inch thick and a foot ſquare: being of a tough nature and nailed down to the rafters, they are not liable to the inconvenience of being broken by forks, like tiles or ſlates [c].

On account of the valuable qualities of the wood therefore, the Larch deſerves to be cultivated in this country. Another recommendation of it is, its quickneſs of growth. Eight trees being meaſured in the ſpring and autumn of the year 1794, the average of their increaſe in height was nearly three feet nine inches and a quarter; and one of them increaſed three inches in circumference at two feet above the ground. In another plantation, the trees at eight years growth meaſured above twenty feet in height on an average; the trees were from ſix to nine inches high when planted. At twelve years old they meaſured, on an average from thirty-four to thirty-ſix feet in height. This plantation was on a good ſoil and in a favourable ſituation.

Nor is it only while the tree is young that it makes theſe vigorous ſhoots; for it appears by the meaſurement of the trees in Dunkeld, that this in a great meaſure continues even till a period of age beyond that which they have as yet attained: for 120 feet in fifty years gives an average of nearly two feet and a half in height for each year of their growth [d].

According to Mr. Harte, it grows ſlowly the firſt four years; but in twenty years, will exceed a Fir tree both in height and circumference that is double its age. Nor is there any reaſon, he adds, for doubting whether this tree will thrive in England: for ſome Larches about forty years ago came to full ſize and perfection near Chelmsford in Eſſex; and Mr. Miller mentions others of a conſiderable growth at Wimbledon in Surry, which produced a large quantity of cones every year [e]. This was ſaid at leaſt as far back as the year 1770: and Mr. Evelyn ſpeaks of a Larch at Chelmsford.

The Biſhop of Landaff informs us, that from many experiments made by himſelf, and collected from others, he finds the annual increaſe in circumference of the Larch, at ſix feet from the ground, to be one inch and a half on an average of ſeveral years; and that this inference has been drawn from the actual admeaſurement of Larches in different parts of England and Scotland, and of different ages from ten years old to fifty [f].

In making a plantation of Larch, the thinnings may be applied to a variety of uſeful purpoſes, whilſt they are yet of a ſmall ſize. In ſix, eight, or ten years, according to ſoil and circumſtances, the trees will have attained a ſize ſufficient to be made into hay-rakes. They grow ſo ſtraight, and the wood is ſo light, ſtrong and durable, as to be peculiarly calculated for this purpoſe; and from its ſhrinking leſs than any other wood, theſe rakes will remain longer firm than thoſe made from any other. About two feet cut off from the root end will form the rake-head; and five feet above that, with a very little taken off from the thickneſs of the under part, will form the handle. No wood is more proper for the teeth of the rake, than ſome of the red wood of an older tree, becauſe it is not only tough, but little liable either to ſplit or ſhrink. The bow may be made of Aſh, or of the laurel leaved ſweet-ſcented Willow, (*Salix pentandra*) which is ſtill better. Nothing is ſo fit for ſhafts to hoes; for it is nearly as ſtrong, and much more durable than Aſh. Handles for bruſhes, brooms, ſcythes, &c. would occaſion a vaſt conſumption of theſe ſmall ſpars.

Light, neat and ſtrong chairs, for ruſh bottoms, might be made of Larch wood at this age.

Nothing will anſwer better for hop-poles; for one ſet of theſe would outlaſt two or three ſets of Aſh. Hurdles, ſpars and gates, may be made of it, both lighter and more durable than of any other wood: and when the trees are of a ſize ſufficient, they may be ſplit down for cart ſhafts; and in mining countries they might be employed as poſts for ſupporting the roofs of the mines.

The ſmall tops cut off in making theſe various works, would furniſh a neat, elegant, cheap and durable kind of railing, to be put upon the top of low walls, eſpecially for preventing light ſheep from over-leaping them. One end might be let into the coping, whether of ſod clay or lime; and the other end received into a ſlip of ſawn Larch wood, with holes bored through it to receive their points. From the ſtraightneſs of the wood, this kind of rail would be very neat without much expenſe. In the ſame manner hen-coops, crates for packing glaſs, &c. might be made of thoſe materials.

But one of the moſt extenſive and beneficial uſes of this kind of ſmall wood, is for the purpoſe of incloſing. Theſe ſpars, when the root is thick enough, may be ſlit up the middle by a ſaw, and cut into lengths of five or ſix feet; or if ſmaller they may be employed whole. As they are always ſtraight, and nearly of an uniform thickneſs, if driven into the ground for a few inches in a row, at the diſtance of a few inches from each other, with the ſplit ſides all one way, they would make one of the neateſt and moſt complete fences that can be ſeen. The tops of theſe uprights may be received into a piece of ſawed plank, with holes bored in it for that purpoſe; and ſupported at due diſtances by ſloping pieces reaching from the ground to the top.

[f] Agricult. ſurvey of Weſtmoreland, prelim. obſervations.

These are a few of the uses to which the small spires from the first thinnings of the plantations may be applied. As they advance to a larger size, for windows, joists, flooring, panelling, couples, rafters, and every other purpose in building, they would be superior to any other kind of wood hitherto employed for these purposes; and for ship-building, especially planks, it would be superior to Oak itself.

There is not a branch or a twig of the Larch, that may not be put to some useful purpose. The larger branches may be employed in fencing, and the smaller brush for filling drains and for fuel. In drains, it is more durable than any other wood; and though the timber will not burn readily, yet the brush is found to make a fire almost equal to the billets of many other trees[f].

The acknowledged utility of the Larch induced the truly respectable Society for the encouragement of Arts, Manufactures and Commerce, at London, to offer very early both honorary and pecuniary rewards for the propagation of this tree; and so long since as the year 1758 three gold medals, and a premium of thirty pounds had been bestowed by the Society for planting Larch, and giving an account of the utility of the wood.

This attention of the Society, and a conviction of the superior qualities of the Larch impressed upon the minds of gentlemen in various parts of these kingdoms, has induced them to make some considerable plantations; and we are informed by Mr. Drummond, of Blair Drummond in Scotland, son to the late Lord Kaims, that by the great plantations of Larch, yearly made both in England and Scotland, the value of this excellent tree is now well understood; and if these plantations are continued for some years with the same spirit, there can be little doubt, that in half a century, the many thousand pounds annually sent to Norway for timber, will be entirely saved to this country[g].

Some of these plantations are the following.—John Sneyd, Esq. of Belmont in Staffordshire, between the years 1784 and 1786, planted 13000 Larches.

The present Bishop of Landaff has planted on high ground near Ambleside in Westmoreland above an hundred acres with mixed timber trees, among which are 48500 Larches. These were planted in 1787 and 1788.

Joseph Cowlishaw, of Hodsock Park, Esq. planted 27,400.

William Mellish, Esq. of Blyth, 47,500.

Richard Slater Milnes, Esq. of Foyston near Ferrybridge in Yorkshire, 200,000, transplanted from two to four years old, 2000 on an acre.

Mr. George Wright, of Auston, at Gilding-wells in the county of York, 11,573.

Thomas White, Esq. of West Retford, in Nottinghamshire, 13,000.

John Holliday, Esq. of Dillorn in Staffordshire, 7900.

All these were planted chiefly in the year 1789.

In Scotland: George Ross, Esq. of Cromarty, planted 1900.

But the Earl of Fife has been the great planter there. He planted in the county of Moray 181,813 Larches.

The Rev. Thomas Dunham Whitaker, at Holme in Claviger in the county of Lancaster and parish of Whalley, planted 64,135 Larches, between june 1790 and june 1791. They were between two and four years old.

Mr. Thomas Gaitskell, of Little Braithwait in Cumberland planted 43,300 on fifteen acres of high land, between the first of february and the first of april 1791.

Between june 1794 and june 1795, John Sneyd, Esq. above-mentioned planted 11,000 more Larches, at Belmont in Staffordshire[h].

These amount in the whole to 599,621, and doubtless there are many more plantations which have not come to my knowledge.

[f] Anderson's Essays, vol. 3. 407 to 422.
[g] Transact. Arts, vol. 7. for 1789.
[h] Transact. Soc. Arts.

The Duke of Athole, alone, says Dr. Anderson, plants 200,000 Larches every year; and one nurseryman at Edinburgh has raised this year (1796) above five millions.

A valuable produce of the Larch tree is the Venice Turpentine, which issues spontaneously from the bark, but is more commonly obtained by boring a hole with an auger about two feet above the ground, till it reaches near to the heart of the tree, into this hole is inserted a small pipe or cock, through which the turpentine flows into proper vessels placed for its reception. This process is continued from the end of may till the end of september. When the trees will yield no more for that season, the turpentine is pressed through a cloth to purify it. This is usually thinner than any of the other sorts, of a clear whitish or pale-yellowish colour, a hot pungent bitterish disagreeable taste, and a strong smell, without any thing of the aromatic flavour of the Chian or Cyprus Turpentine obtained from *Pistacia Terebinthus*. The common and Strasburgh Turpentine is from the *Pinus Picea*: and the Canada balsam, which may be considered as the purest of the Turpentines, is procured from the Silver and Balm of Gilead Firs.

The turpentine is not to be obtained in considerable quantities from very young trees, and in old ones it gradually dries up, till at last it affords none: it is only after the tree has attained the thickness of ten or twelve inches in diameter, that it is thought worth while to collect the turpentine; and from that time, during forty or fifty years, if it continues so long in vigorous growth, the tree will continue to yield annually from seven to eight pounds of turpentine.

An English acre will contain 682 trees, at the distance of eight feet from each other. Suppose the annual produce to be six pounds a tree on an average, and the price to be no more than two-pence the pound, (the common turpentine that the painters use is now, 1799, six-pence a quart) the value of the produce would be 3l. 4s. 2d. the acre; on supposition that the trees would yield as much turpentine in Britain, as on the borders of the Adriatic gulf. Whether they will do so, remains to be ascertained by experiment.

All the turpentines dissolve totally in rectified spirit: they become miscible with water into a milky liquor, by the mediation of the yolk or white of an egg, and more elegantly by mucilages. Distilled with water they yield a subtile penetrating essential oil, vulgarly called spirit; a yellow or blackish resin remaining in the still, which is the common rosin of the shops. The essential oil, on being distilled in a retort, becomes more subtile, and in this state is called ethereal oil of turpentine.

The turpentines stimulate the first passages, and prove laxative; and we are told by Dr. Cullen, that half an ounce or an ounce of Venice turpentine, triturated with the yolk of an egg, and diffused in water, may be employed in the form of an injection, as the most certain laxative in colics, and other cases of obstinate costiveness. When turpentine is carried into the blood-vessels, it stimulates the whole system; hence its use in chronic rheumatism and paralysis. It readily passes off by urine, which it imbues with a peculiar odour; also by perspiration, and probably by exhalation from the lungs: and to these respective effects are to be ascribed the virtues it may possess in gravelly complaints, scurvy and pulmonic disorders. In all these diseases however, and especially the last, this medicine, as well as some of the gums and balsams of the terebinthinate kind, by acting as stimulants, are often productive of mischief, as was first observed by Boerhaave, and since by Fothergill.

Turpentine has been much used in gleets and fluor albus; its efficacy in the former Dr. Cullen ascribes to its inducing some degree of inflammation in the urethra.

The essential oil, in which the virtues of turpentine reside, is not only preferred for external use, as a rubifacient, &c. but also internally as a diuretic; and by Pitcairne and Cheyne, as a remedy for the sciatica; but few stomachs are able to bear it in the doses they direct.

Turpentine,

Turpentine, ſo much uſed formerly as a digeſtive application, is in modern ſurgery almoſt wholly exploded [1].

Beſides this well known product the Larch yields alſo a Manna and a Gum. The Manna is found in the South of France, and is called there *Manne de Briançon:* it is white, concrete and ſweet, like fine new honey. It is rare, and met with only in little drops, ſo that it would be very difficult to collect a pound of it. The drops are more or leſs hard, and adhere to the leaves.

Monſ. Villars having made ſome enquiries relative to this ſubſtance, with Monſ. Guettard in the year 1773, found it at ſun-riſe almoſt fluid; and picked up drops of it on the turf exactly like thoſe which remained on the trees; but they have not given any analyſis or farther account of it, except that the ſeaſon of 1773 was leſs productive of Manna than uſual [2]. Laſt year (1798) I obſerved a Larch near my houſe covered with a hoary powder, but I neglected to examine whether it had any of the qualities of Manna. In the preſent year there is no appearance of it. The laſt ſeaſon was a hot dry one, and therefore favourable to the production of Manna; and the ſeaſon of 1799 has been a cold wet one.

Pallas informs us that they have this Manna in the Ruſſian empire, but that it is rarely found concrete, being commonly ſoon waſhed off by the rains which are frequent on the Uralian mountains.

He remarks alſo, that the turpentine reſides in the bark and the wood next to it, as is apparent when the trunk of a Larch is ſawed tranſverſely; for then it may be ſeen that the inner wood for more than half the diameter is dry. It cannot therefore be of any uſe to drive the auger almoſt to the centre of the tree, as Dr. Anderſon recommends.

Pallas alſo mentions a Gum that is yielded by the Larch in particular circumſtances. When the woods are on fire, which frequently happens in Ruſſia, the Larches are eaſily burnt on the ſide next the flame to the height of ſeveral feet, on account of the turpentine in which they abound. If the wood happens to be ſcorched to the pith, the inner part exudes a dry, reddiſh gum, rather leſs glutinous than Gum Arabic, having a ſlight taſte of reſin, but wholly ſoluble in water. It is uſed in medicine; and the native mountaineers chew it to faſten their teeth, as an antiſcorbutic, and as a ſubſtance highly nutritive; they alſo uſe it as a glue to faſten their bows, &c.

The Siberian hunters of Ermines, when their ferment or yeaſt which they carry with them to make the acid liquor which they call *Quaſs* with, is ſpoiled by the cold, ſcrape off the albumen or half-formed wood between the bark and the wood, which is very juicy and ſweet, digeſt it with water over the fire during an hour, mix it with their rye meal, bury the dough in the ſnow, and after twelve hours find the ferment ready prepared in the ſubſiding feces [3].

Old Larches produce a Fungus, which is deſcribed very much at large by Jacquin, in the firſt volume of his Miſcellanea, under the name of *Boletus Laricis.* It is alſo called *Agaricus purgans:* and is uſed in the northern countries as an emetic in intermitting fevers. The Tunguſes dye the hair of the rein deer with this Fungus and the roots of Galliſum, of a very deep red colour; whence perhaps it may be of ſome uſe in dyeing. The body of this Fungus is ſaponaceous, and is uſed by the women in ſome parts of Siberia, to waſh themſelves, and even their linen [4]. It was celebrated formerly, but is now deſervedly fallen into total diſuſe, as a medicine.

From the Pines properly ſo called, with the Cedar and Larches their allies, we proceed now to the Firs, which are diſtinguiſhed from them by having the leaves ſingle and diſtinct at the baſe; whereas the former have them two or more, or even in bundles from the ſame ſheath.

15. The Silver Fir is a noble upright tree. The branches are not very numerous, but the bark is ſmooth and delicate. The upper ſurface of the leaves is of a fine ſtrong green, and their under has two white lines running lengthwiſe on each ſide of the midrib, giving the leaves a ſilvery look, from which this Fir takes its name. The cones are large and grow erect; and when warm weather comes on they ſoon ſhed their ſeeds [5]. The ſcales are wide, deltoid, rounded above, below beaked, and appendicled with a membranaceous ſpatulate dorſal ligule, terminated by a recurved dagger-point. Nuts rather large, membranaceous, variouſly angular, dun-coloured. Wing covering the whole nut on one ſide, but half of it only on the other, membranaceous, widening upwards, obliquely truncated at top. Albumen gibbous, opaque. Embryo with five cotyledons, of a yelloviſh colour [6].

Native of Switzerland and Germany, (Dauphiné, Auſtria, Siberia, mount Caucaſus, &c.)

Cultivated in 1739, in Cheſſea garden [7]: but as thirty-ſix fine trees are mentioned by Plot and Ray, as growing near Newport in Shropſhire, it muſt have been here much ſooner [8].

Evelyn alſo mentions two Spaniſh or Silver Firs then growing in Harefield-park, Middleſex, belonging to Mr. Serjeant Newdigate, that were planted there in 1603, at two years growth from the ſeed, the biggeſt of which was eighty-one feet high, and thirteen feet in circumference below; the length, ſo far as it is timber, that is, to ſix inches ſquare, ſeventy-three foot, in the middle ſeventeen inches ſquare, and containing 146 feet of good timber.]

Mr. Miller ſays, it is ſuppoſed, that moſt, if not all all theſe trees in Germany were originally planted there; that Tournefort, in his travels, mentions the Firs of mount Olympus as the moſt beautiful trees in the Levant, and that he has received cones from thence upwards of a foot in length.

[Though Linnæus, and ſeveral other writers on the Materia Medica refer the common Turpentine to the Pinus ſylveſtris, and the Straſburgh Turpentine to this; yet Murray, following Haller and Duhamel aſcribe the common Turpentine to the Silver Fir, which pours it out ſo freely, that it is ſeldom neceſſary to make inciſions through the bark for that purpoſe [9].

It has been obſerved in Ireland, that no tree grows ſpeedily to ſo large a ſize as the Silver Fir. Some at forty years growth, in a wet clay on a rock, meaſuring twelve feet in circumference at the ground, and ſeven feet and a half at five feet high; one containing ſeventy-ſix feet of ſolid timber. It is found to be excellent for boat-building. A gentleman in Hampſhire floored his library with Silver Fir freſh cut down, and the boards did not contract in the leaſt [10].

The Earl of Fife alſo remarks, that no trees make a greater progreſs than this and the Larch.

16. This beautiful tree riſes with an upright ſtem. The leaves are dark green on their upper ſurface, and marked with whitiſh lines underneath. The cones are roundiſh and ſmall. The buds and leaves are remarkably fragrant. From wounds made in this tree a very fine Turpentine is obtained, which is ſometimes ſold for the true Balm of Gilead [11]. Though it grows to a large ſize in America, yet it has not done ſo with us [12].

The Balm of Gilead Fir has very much the habit of the Silver Fir, but the leaves are wider and blunter, diſpoſed on each ſide along the branches like the teeth of a comb, but in a double row, the upper one ſhorter than the under; underneath they are marked with a double glaucous line, and each has eight rows of white dots; they are often cloven at top [13].]

It was formerly growing (1696) in the Biſhop of London's garden at Fulham; and of late years a great number of the trees have been raiſed from ſeeds brought from Virginia, where it is a native. It makes very little progreſs after eight or ten years growth; the only place in which the trees have made any figure is at his Grace the Duke of Bedford's at Woburn Abbey in Bedfordſhire.

17. [The Hemlock Spruce Fir is a beautiful but delicate tree, and muſt have a good ſoil, with a warm

ſituation.

ſituation. It will be improved by tying its leading ſhoot to a ſtake annually as it advances [a].

The cone is of the ſize and ſhape of a ſmall hen's egg, the whole of an aſh-coloured bay. Scales coriaceous, thick, triangular, the outer ſide rounded and ſomewhat crenulate. Nuts a little ſmaller than in the Black Spruce, with a winged membrane on the outer ſide only. Wings ovate-oblong, nearly equilateral, or not ſo gibbous on the outer ſide, as in the Black Spruce. Seed ovate, acuminate downwards. Embryo like that of the Black Spruce in ſituation and ſhape, but with four cotyledons [b].]

It is a native of many parts of North America. It does not thrive well in any part of England, nor in many parts of America; though in ſome particular ſpots I have been informed there are very large high trees now growing.

[It was introduced in 1736, by Peter Collinſon, Eſq.[c]

18. The Black Newfoundland Spruce has ſhorter leaves, whiter on their under ſide than the White; the cones alſo are ſmaller and more compact. There is alſo a Red Spruce; but there ſeems to be no difference between this and the Black, either in the cones which have been brought from Newfoundland, or the young plants which have been raiſed in our gardens.

The appellations of White and Black are given from the colour of the bark, for there is little difference in the colour of the wood, and the leaves of the Black are whiter on their under ſide than thoſe of the White. Both are natives of North America; the White upon the mountains, the Black upon the low grounds, generally in bogs or ſwamps. The firſt is by much the largeſt tree. Few of theſe trees are now remaining near the European ſettlements, but farther up in the country they are in great plenty.

The cones both of the Black and White Spruce were ſent from Virginia to England by Mr. Baniſter, towards the end of the laſt century; and ſeveral of the plants were raiſed in the gardens of Compton Biſhop of London at Fulham, Mr. Reynardſon at Hillendon near Uxbridge, and Mr. Darby at Hoxton; but theſe were ſoon deſtroyed, after the death of their poſſeſſors. About the ſame time cones were brought from Newfoundland to Devonſhire, where there are now (1755) ſome large trees growing, which have produced cones for thirty years paſt; but except theſe, I believe there are few, if any of theſe trees now in England, which are of above twenty years growth. The fineſt in theſe parts are in the curious gardens of his Grace the Duke of Argyle, at Whitton in Middleſex. From both the ſorts exudes a fine clear reſin, of a ſtrong ſcent, much uſed by the native Indians to cure wounds, and in internal diſorders. The branches of both ſorts are alſo uſed indifferently in making Spruce-Beer.

This ſort is eaſily known by its narrow leaves, placed on every ſide of the branches, and its long pendulous cones, which do not fall to pieces on the tree, but drop off entire the following ſummer: the ſcales open and emit the ſeeds on the firſt warmth of the ſpring.

A variety of this tree is cultivated in the gardens near London, called the long-coned Corniſh Fir. The leaves are longer, broader, of a lighter colour, and fuller on the branches; the cones alſo are longer. From the appearance of the old trees they may be taken for diſtinct ſpecies; but ſince both are produced from ſeeds of the ſame cone, they are certainly only ſeminal varieties [b].

According to Gærtner, the cone is ovate, ſmall, being ſcarcely the ſize of the outer joint of the thumb: ſcales imbricate, coriaceous, rounded, dun-coloured, large in proportion to the ſize of the cones. Nut ſmall, bony, one-celled, valveleſs, entirely covered with an epidermis, which widens into a membranaceous wing, longer than the nut, ſtraight on one ſide, gibbous on the other. Receptacle none, except the inner ſurface of the ſcales, to the baſe of which the two nuts are faſtened. Seed ſingle, of the ſame ſhape with the cavity of the nut, pale yellow: cover ſingle, very thin, membranaceous: albumen thick, fleſhy, white: embryo nearly the length of the albumen, roundiſh, erect, milky: cotyledons three, very ſhort, angular, fleſhy: radicle long, roundiſh, inferior.

19. The Norway Spruce Fir is the loftieſt of our European trees, attaining a height from 125 to 150 feet, with a very ſtraight trunk, and throwing out its ſpreading branches ſo as to form an elegant pyramid. Leaves cluſtered, without order, from an oblong cortical ſcale, four-cornered, drawn out into a ſharp point, thickiſh, commonly curved a little; as Linnæus obſerves, compreſſed, ſlightly keeled on both ſides, ſhining on the upper ſurface. Male cones or catkins ovate, ſcattered in the axils of the leaves, purple. The young female cones are alſo purple; when ripe pendulous [c]. They have eight rows of ſcales in a ſpiral, each row having from twenty to twenty-three ſcales, in each of which are two ſeeds, and conſequently about 365 in a cone [d].

The ſcales are obovate-rhomboidal, terminating in a dagger point, not appendiculed. Nuts ſmalliſh, ovate, acuminate downwards, flatted a little, cruſtaceous, blackiſh-brown: wing covering the nut only on the outer ſide, membranaceous, elliptic, thin. Albumen ſubpellucid, of a watery colour. Embryo milky, having nine cotyledons [e].

The vaſt woods of Denmark, Norway, Sweden, &c. are principally compoſed of Pinus ſylveſtris, which we call Scotch Pine, becauſe it abounds in Scotland, and is the only tree of this genus which is indigenous there, and this ſpecies of Spruce Fir, which we commonly call Norway Spruce, becauſe we import the timber of this tree chiefly from Norway. There are two principal varieties of it, the White and the Red, but both afford the white deals. Gærtner ſays that they are called ſo from their paler or deeper colour of the cones, and that they agree in the want of the ligules on the back of the ſcales, by which they are diſtinguiſhed with greater evidence and certainty from Pinus Pinea than by the leaves. Linneus has five varieties in his Flora Suecica, but they are inſignificant.

In the Kew catalogue it is ſaid that the Norway Spruce was cultivated in Cheliea garden in 1739: but we probably had it much earlier; for Mr. Evelyn ſpeaks of Sir Norton Knatchbull's delicious plantation of Pines and Firs, which he beheld with great ſatisfaction, and where a Fir-tree of the Knight's own raiſing ſhot no leſs than ſixty feet in height, in little more than twenty years; of Sir Peter Wentworth's, of Lillingſton-level; Cornbury in Oxfordſhire, and other places; but eſpecially thoſe trees growing now in Hareſield-park in the county of Middleſex [f].

Theſe might poſſibly be North American Firs; but it is ſcarcely credible that the Norway Spruce ſhould not have been introduced here before 1739; though I have not at preſent found any direct evidence for it.

As to the immenſe foreſts of Fir or Pine diſcovered underground in various parts of theſe kingdoms, they were probably the Pinus ſylveſtris or Scotch Pine: for the ſubterraneous cones which I have ſeen evidently belonged to this ſpecies: and hence, after all, Julius Cæſar may be right in affirming that neither the *Fagus* nor the *Abies* were in his time indigenous of Britain, if the Fagus be a ſpecies of Oak, and the Abies the Norway Spruce Fir, which does not now, and probably never did grow wild in this iſland: whereas great quantities of Scotch Pine were cut down by the Romans, to diſencumber the country, and deſtroy the retreats of the ſavage inhabitants [g].

The timber of the Spruce Fir is well known to be inferior to that of the Pinus ſylveſtris; the former affording the white, the latter the red deal. This however, ſays Haller, is what is chiefly uſed in Switzerland for maſts, beams, joiſts, ſpars, and an infinity of utenſils and inſtruments; charcoals, though not the hardeſt, for fuſing metals; reſin collected to the quantity of forty pounds from a tree in one year, pitch, tar, &c. [h]

[a] Boutcher. [b] Mill. fig. p. 1, 2. [c] Gærtner. [d] Hort. kew. [e] Haller. [f] Linn. [g] Gærtner. [h] Silva, p. 141. [i] Idem, 145. [k] Haller. helv. 412.

Fir was anciently uſed, ſays Evelyn, for building ſhips; it is ſtill uſed for the maſts, and ſome other parts, but ſeldom for the entire veſſel, except in ſmall craft. Its great conſumption now among us is for the interior work of our houſes; beams, joiſts, rafters, ſpars, doors, floors, wainſcot; all being made of this wood, almoſt to the excluſion of any other. Scaffold-poles, balks, laths, boxes, and bellies for muſical inſtruments are made of Fir. It is exceeding ſmooth to poliſh on, and therefore does well under gilding work, and takes black equal with the Pear tree. It ſucceeds well in carving, the grain being eaſy to work, and taking the tool every way. No wood takes glue ſo well, or is ſo eaſily wrought. Caſes and barrels for dry goods, ſhingles, hoops, &c. are made of it. It yields pitch, tar, turpentine and reſin; and from the buds and tops ſpruce beer is made, accounted ſo excellent againſt the ſcurvy.

No tree will yield greater profit than the Spruce Fir in cold land, no tree is more beautiful ſtanding ſingle on turf in large plantations, or more uſeful for ſhelter in cold ſoils and ſituations.

An inciſion being made into the bark, a clear tenacious fluid iſſues, which concretes into a reſinous ſubſtance, known by the name of *Reſina Abietis*. This, after being boiled in water, and ſtrained through a linen cloth, is called in the Pharmacopœias *Burgundy Pitch*. But if the boiling of the native reſin is continued till the water is wholly evaporated, and wine vinegar is at this time added, a ſubſtance named *Colophonium* is formed.

Burgundy Pitch, which is chiefly imported from Saxony, is of a ſolid conſiſtence, yet ſomewhat ſoft, of a reddiſh brown colour, and not diſagreeable in ſmell. It is entirely confined to external uſe, and was formerly an ingredient in ſeveral ointments and plaſters. In inveterate coughs, affections of the lungs, and other internal complaints, plaſters of this reſin, by acting as a topical ſtimulus, are frequently found of conſiderable ſervice[1].

Freſh cones boiled in whey; and beer brewed with pine-tops are accounted good in inveterate ſcurvies.

Even the air impregnated with the exhalations of Fir-trees is reckoned very wholeſome, particularly for phthyſicky perſons. Reſin melted with bees-wax, and ſtirred about, or ſmall pellets of pitch thrown into the fire, or on heated plates of iron, are eſteemed uſeful in the aſthma.

20. For the diſtinction between this and the Black Spruce ſee n. 18.

21. This was found by Tournefort in the Levant.

Gærtner remarks a ſingularity in this genus, that the number of cotyledons differs in the different ſpecies. The *ſylveſtris* has five, *Cembra* twelve, *Cedrus* ſix, *Larix* two, *Picea* five, *nigra* three, *canadenſis* four, *Abies* nine. Hence he recommends the cotyledons of the ſeeds, as well as the cones, to be called in for ſpecific differences, when the leaves are not ſufficient[2].

According to Linnæus, *P. Strobus* or Weymouth Pine has from ſix to ten cotyledons; and is the connecting link between *Pinus* and *Abies*, the Pines and the Firs.

Juſſieu, following Tournefort, makes two genera of *Pinus* and *Abies*: the former having from two to five leaves coming out from each ſhort cylindrical ſheath; the aments or male catkins not ſolitary, but compacted into a terminating raceme, according to the obſervations of Duhamel and Lamarck; the ſtrobiles or cones terminating: the latter, with which he joins the *Larix*, though he doubts whether it ought not rather to be ſeparated, having the leaves alternate, linear, acuminate, ſingle or diſtinct, except in the *Larix*, which has them in bundles, and not evergreen, but deciduous; both aments and cones are ſolitary and terminating, except in the *Larix*, which has them ſcattered over the ſtem or axillary, as Duhamel remarks. The genuine *Abietes* are balſamiferous, with a flatted foliation, and ſtraight cones: the *Piceæ* are reſiniferous, with a circular foliation, and inverted cones[3].

[1] Woodville. [2] Vol. 2. p. 61. [3] Genera, 415.

These diſtinctions deſerve to be attended to, but they are not ſufficient to induce us to lacerate a natural genus.]

PROPAGATION AND CULTURE.

All the ſorts of Pines are propagated by ſeeds, which are produced in hard woody cones; the way to get out their ſeeds is to lay the cones before a gentle fire, or in the ſun, which will cauſe the cells to open, and then the ſeeds may be eaſily taken out. If the cones are kept entire, the ſeeds will remain good for ſome years; ſo that the ſureſt way to preſerve them, is to let them remain in the cones until the time forſowing the ſeeds; if the cones are kept in a warm place in ſummer, they will open, and emit the ſeeds; but if they are not expoſed to much heat, they will remain entire ſome years, eſpecially thoſe which are cloſe and compact; and the ſeeds which have been taken out of cones of ſeven years old, have grown very well, ſo that theſe may be tranſported to any diſtance, provided the cones are well ripened and properly put up.

The beſt time for ſowing the ſeeds of Pines is about the end of march, and when the ſeeds are ſown, the place ſhould be covered with nets to keep off birds, otherwiſe, when the plants begin to appear with the huſk of the ſeed on their tops, the birds will pick off the heads of the plants and deſtroy them.

Where the quantity of ſeeds to be ſown is not great, it will be a good way to ſow them either in boxes or pots, filled with light loamy earth, which may be removed from one ſituation to another, according to the ſeaſon of the year; but if there is a large quantity of the ſeeds, ſo as to require a good ſpace to receive them, they ſhould be ſown on an eaſt or north-eaſt border, where they may be ſcreened from the ſun, whoſe heat is very injurious to theſe plants at their firſt appearance above ground. Thoſe ſeeds which are ſown in pots or boxes, ſhould alſo be placed in a ſhady ſituation, but not under trees; and if they are ſcreened from the ſun with mats at the time when the plants firſt come up, it will be a good method to preſerve them.

Moſt of the ſorts will come up in about ſix or ſeven weeks after they are ſown, but the ſeeds of the Stone or cultivated Pine, and two or three of the others, whoſe ſhells are very hard, frequently lie in the ground a whole year; ſo that when the plants do not come up the firſt year, the ground ſhould not be diſturbed, but kept clean from weeds, and the following ſpring the plants will riſe. This frequently happens in dry ſeaſons, and when they are ſown in places a little too much expoſed to the ſun. Therefore the ſureſt method is, to ſoak the ſeeds in water twenty-four hours before they are ſown.

When the plants appear, they muſt be conſtantly kept clean from weeds; and in very dry ſeaſons, if they are now and then gently refreſhed with water, it will forward their growth; but this muſt be done with great care and caution, for if they are haſtily watered, it will waſh the tender plants out of the ground, or lay them down flat, which often rots their ſtalks; and when this is too often repeated, it will have the ſame effect; ſo that unleſs it is judiciouſly performed, it will be the beſt way to give them none, but only ſcreen them from the ſun.

If the plants come up too cloſe, it will be a good method to thin them gently about the beginning of July. The plants which are drawn up may then be planted on other beds which ſhould be prepared ready to receive them, for they ſhould be immediately planted as they are drawn up, becauſe their tender roots are ſoon dried and ſpoiled at this ſeaſon of the year. This work ſhould be done (if poſſible) in cloudy or rainy weather, and then the plants will draw out with better roots, and will ſoon put out new fibres again; but if the weather ſhould prove clear and dry, the plants ſhould be ſhaded every day from the ſun with mats, and now and then gently refreſhed with water. In drawing up the plants, there ſhould be great care taken not to diſturb the roots of the plants left remaining in the ſeed-beds, &c. ſo that if the ground be hard, the beds ſhould be well watered ſome time before the plants are thinned, to ſoften and looſen the earth; and

and if after the plants are drawn out, the beds are again gently watered to ſettle the earth to the roots of the remaining plants, it will be of great ſervice to them, but it muſt be done with great care, ſo as not to waſh out their roots, or lay down the plants. The diſtance which ſhould be allowed theſe plants in the new beds, is four or five inches row from row, and three inches in the rows.

In theſe beds the plants may remain till the ſpring twelve months after, by which time they will be fit to tranſplant where they are to remain for good, for the younger the plants are when planted out the better they will ſucceed; for although ſome ſorts will bear tranſplanting at a much greater age, yet young plants planted at the ſame time, will in a few years overtake the large ones, and ſoon outſtrip them in their growth; and there is an advantage in planting young, by ſaving the expenſe of ſtaking, and much watering, which large plants require. I have often ſeen plantations of ſeveral ſorts of Pines, which were made of plants ſix or ſeven feet high, and at the ſame time others of one foot high planted between them, which in ten years were better trees than the old ones, and much more vigorous in their growth; but if the ground where they are deſigned to remain cannot be prepared by the time before-mentioned, the plants ſhould be planted out of the beds into a nurſery, where they may remain two years, but not longer; for it will be very hazardous to remove theſe trees at a greater age.

The beſt ſeaſon to tranſplant all the ſorts of Pines is about the latter end of march or the beginning of april, juſt before they begin to ſhoot; for although the Scotch Pine, and ſome of the moſt hardy ſorts, may be tranſplanted in winter, eſpecially when they are growing in ſtrong land, where they may be taken with balls of earth to their roots; yet this is what I would not adviſe for common practice, having frequently ſeen it attended with bad conſequences, but thoſe which are removed in the ſpring rarely fail.

Where theſe trees are planted in expoſed ſituations, they ſhould be put pretty cloſe together, that they may ſhelter each other; and when they have grown a few years, part of the plants may be cut down to give room for the others to grow; but this muſt be gradually performed, leſt by too much opening the plantation at once, the air ſhould be let in among the remaining trees with too great violence, which will ſtop their growth.

Although theſe Evergreen-trees are by many perſons deſpiſed on account of their dark green in ſummer, yet a proper mixture of theſe in large clumps make a fine appearance about a ſeat in winter, and in ſummer, by their contraſt with other trees, have no bad effect in diverſifying the ſcene.

Wherever large plantations are deſigned to be made, the beſt method will be to raiſe the plants either upon a part of the ſame land, or as near to the place as poſſible, and alſo upon the ſame ſort of ſoil: a ſmall piece of ground will be ſufficient to raiſe plants enough for many acres, but, as the plants require ſome care in their firſt raiſing, if the neighbouring cottagers, who have many of them ſmall incloſures adjoining to their cottages, or where this is wanting, a ſmall incloſure ſhould be made them for the purpoſe of raiſing the plants, and they are furniſhed with the ſeeds and directions for ſowing them, and managing the young plants till they are fit for tranſplanting, the women and children may be uſefully employed in this work; and the proprietors of land agreeing with them to take their plants when raiſed at a certain price, it would be a great benefit to the poor; and hereby they would be engaged to have a regard for the plantations when made, and prevent their being deſtroyed.

The Scotch Pine, as was before obſerved, being the hardieſt of all the kinds, and the wood of it the moſt uſeful, is the ſort which beſt deſerves care. This will thrive upon the moſt barren lands, where ſcarce any thing elſe except Heath and Furze will grow; and there are many thouſand acres of ſuch land lying convenient for water carriage, which at preſent are of little benefit to any body, that might, by plantations of theſe trees, become good eſtates to their proprietors, and alſo a national benefit; and as the legiſlature has taken this into conſideration, and already paſſed ſome laws for encouraging theſe plantations, as alſo for their preſervation and ſecurity, it may be hoped that this will be undertaken by gentlemen who are poſſeſſed of ſuch lands in all the different parts of the kingdom with proper ſpirit; for although they may not expect to receive much profit from theſe plantations in their own time, yet their ſucceſſors may with large intereſt; and the pleaſure which thoſe growing trees will afford them, by beautifying the preſent dreary parts of the country, will in ſome meaſure recompenſe them for their trouble and expenſe; and by creating employment for the poor, leſſen thoſe rates which are now ſo high in many parts of England as ſcarce to be borne.

The expenſe of making theſe plantations is what moſt people are afraid of; but the greateſt expenſe is that of fencing them from the cattle, &c. for the other is trifling, as there will be no neceſſity for preparing the ground to receive the plants; and the charge of planting an acre of land with theſe plants will not be more than twenty or thirty ſhillings where labour is dear, excluſive of the plants, which may be valued at forty ſhillings more. I have planted many acres of land with theſe trees, which were covered with Heath and Furze, and have only dug holes between to put in the plants, and afterwards laid the Heath or Furze which was cut, upon the ſurface of the ground about their roots, to prevent the ground from drying, and few of the plants have failed. Theſe plants were moſt of them four years old from ſeed, nor was there any care taken to clean the ground afterwards, but the whole left to ſhift, and in five or ſix years the Pines have grown ſo well as to overpower the Heath and Furze, and deſtroy it.

The diſtance which I have generally planted theſe plants in all large open ſituations was about four feet, but always irregular, avoiding planting in rows as much as poſſible; and in the planting, the great care is not to take up the plants faſter than they can be planted, ſo that ſome men have been employed in digging up the plants while others were planting. Thoſe who take up the plants muſt be looked after, to ſee they do not tear off their roots or wound their bark; and as faſt as they are taken up, their roots ſhould be covered to prevent their drying, and put into their new quarters as ſoon as poſſible. In planting them, care ſhould be had to make the holes large enough for the roots, as alſo to looſen and break the clods of earth, and put the fineſt immediately about their roots, then to ſettle the earth gently with the foot to the roots of the plant. If theſe things are duly obſerved, and a proper ſeaſon choſen for performing it, there will be very little hazard of their ſucceeding; but I have ſeen ſome plantations made with plants which were brought from a great diſtance, and had been ſo cloſely packed up as to cauſe a heat, whereby moſt of the plants within had their leaves changed yellow, and few of them have grown, which has diſcouraged others from planting, not knowing the true cauſe of their failure.

After the plantations are made, the only care they require for five or ſix years will be to ſecure the plants from cattle, hares, and rabbits; for if theſe are admitted to them, they will make great deſtruction in a ſhort time: for if the branches are gnawed by hares or rabbits, it will greatly retard the growth of the plants, if not deſtroy them.

In about five or ſix years after planting, the branches of the young trees will have met, and begin to interfere with each other; therefore they will require a little pruning, but this muſt be done with great caution. The lower tier of branches only ſhould be cut off; this ſhould be performed in ſeptember, at which time there will be no danger of the wounds bleeding too much, and the turpentine will harden over the wounds as the ſeaſon grows cold, and prevent the wet from penetrating the wounds. Theſe branches ſhould be cut off cloſe to the ſtem of the plants, and care ſhould be taken in doing this not to break any of the remaining branches of the young trees. This work ſhould be repeated every other year, at each time taking off only the lower tier of branches; for if the plants are much

much trimmed, it will greatly retard their growth, as it does in general that of all trees; but as theſe trees never put out any new ſhoots where they are pruned, they ſuffer more from amputation than thoſe which do.

In thoſe parts of France where they have foreſts of theſe trees, the proprietors always give the faggots to thoſe, who prune their young trees firſt, for their labour, ſo it coſts them no money. At the ſecond pruning the propriet r has one-third of the faggots, and the dreſſers have the other two for their work, and afterwards the faggots are equally divided between the workmen and proprietors, but there muſt be great care taken that they do not cut off more than ſhould be.

In about twelve or fourteen years theſe will require no more pruning, for their upper branches will kill thoſe below where they have not air; but ſoon after this, if the plants have made good progreſs, it may be neceſſary to thin them; but this ſhould be gradually performed, beginning in the middle of the plantation firſt, leaving the outſide cloſe to ſcreen thoſe within from the cold, by degrees coming to them at laſt, whereby thoſe which were firſt thinned will have had time to get ſtrength, and will not be in danger of ſuffering from the admiſſion of cold air. When theſe plantations are thinned, the trees ſhould not be dug up, but their ſtems cut off cloſe to the ground, for their roots never ſhoot again, but decay in the earth, ſo there can no harm ariſe by leaving them, and hereby the roots of the remaining plants are not injured. The trees which are now cut will be fit for many purpoſes; thoſe which are ſtraight will make good putlocks for the bricklayers, and ſerve for ſcaffolding poles, ſo that there may be as much made by the ſale of theſe as will defray the whole expenſe of the planting, and probably intereſt for the money into the bargain.

As the upright growth of theſe trees renders their wood more valuable, they ſhould be left pretty cloſe together, to draw each other up. If they are left eight feet aſunder each way, it will be ſufficient room for their growth; and if at the firſt thinning a fourth part of the trees are taken away, the others may ſtand twelve or fourteen years longer, by which time they will be of a ſize for making ladders and ſcaffold-poles, &c. ſo that from this ſale as much may be made, as not only to pay the remaining part of the expenſe of planting, but rent for the land with intereſt; and the ſtanding trees will be left for the fortunes of younger children.

1. The Scotch Pine grows well upon almoſt every ſoil. I have planted numbers of the trees upon Peat-pits, where they have made great progreſs. I have alſo planted them in clay, where they have ſucceeded far beyond expectation; and upon ſand, gravel or chalk they likewiſe thrive as well. If they do not grow ſo faſt on ſand or gravel as on moiſt ground, the wood is much preferable; for thoſe trees which have been cut down upon moiſt ſoils, where they have made the greateſt progreſs, when they have been ſawn out into boards, have not proved ſo valuable, the wood being white and of a looſe texture; whereas thoſe which have grown upon dry gravelly ground have been nearly equal to the beſt foreign deals: and I doubt not but thoſe plantations, which of late years have been made, will not only turn out greatly to the advantage of their poſſeſſors, but alſo become a national benefit; this therefore is the ſort which I would recommend to be planted on barren lands.

11. The Weymouth Pine alſo is worth propagating, not only for its beauty, but for the ſake of its timber, particularly for maſts.

It grows beſt upon a moiſt light ſoil, not too wet: it will alſo thrive on a loamy ſoil, if it does not approach too near to clay. The ſeeds ſhould be ſown with a little more care than the Scotch Pine, becauſe their ſtems being not ſo ſtrong, they are more apt to go off while young: if therefore they are ſown in the full ground, the bed ſhould be ſcreened with mats from the ſun every day, but expoſed to the dews every night.

If all the plants are removed into beds in july, it will be a ſecure way to preſerve them; but as they grow faſter than the Scotch Pine, they ſhould be planted farther aſunder; their rows ſix inches diſtant, and the plants four inches apart. This will allow them room to grow till the ſpring twelvemonth following; when they may be either tranſplanted where they are to remain, or into a nurſery, where they may ſtand two years to get ſtrength; but the ſooner they are planted where they are to ſtand, the leſs danger there will be of their ſucceeding, and the larger they will grow; for although they will bear tranſplanting at a greater age, yet when they are planted young, they will make much greater progreſs, and grow to a greater ſize.

When the Weymouth Pine has been planted in a ſoft hazel loam, I have frequently meaſured ſhoots of one year, two feet and a half in length; and they have for ſome years continued growing as much. They ſhould have a ſheltered ſituation, for I have obſerved, where the trees have been much expoſed to the ſouth-weſt winds, they have not made near ſo great a progreſs as thoſe which grew in ſhelter; and in large plantations, thoſe on the outſide have not kept pace with thoſe in the middle, nor have their leaves retained their verdure ſo well.

8. The Swamp Pine does well in very few places here; in ſevere froſts the leading ſhoots are often killed; and in dry ground it will not thrive: unleſs the ſoil be favourable, it is to little purpoſe to plant this ſort of Pine.

[6. The ſeeds of the Stone Pine being ſo large, they may be ſet in drills ſix inches aſunder, four inches from each other, and an inch deep. The following ſpring they may be planted out in rows, two feet aſunder, and one foot in the rows; where they muſt continue two years, and then removed to the place they are to remain in [n].

Bradley adviſes Heath land, which is generally ſandy, and in which commonly we find abundance of moraſs ground, to be planted with Fir trees. We have ſome inſtances of this ſort of land cultivated in this manner. At the Earl of Alreſford's, near Guildford in Surry, we have an example of the good thriving of theſe trees upon a hill of common white ſand, in which one could hardly expect the leaſt vegetable quality; and the trees now growing there have not been planted quite thirty years, although they are about forty feet high; but it is to be obſerved that they are hardly ſix feet aſunder, which may be the occaſion of their extraordinary height, and the clearneſs of their ſtems without knots. The experience I have had of theſe trees, eſpecially of the Scotch Pine, teaches me, that they thrive better raiſed from ſeed upon the ſpot where they are deſigned to remain, than if they are tranſplanted.

To make a Seminary of theſe trees gather the cones in ſeptember, even while their rind partakes yet of a green colour; for thoſe which are already cracked and opened produce little or no good ſeed: lay them by in a dry place during the winter, and about february either expoſe them to the ſun till they open, or put them in ſome veſſel into an oven, after the great heat is gone off; by either of theſe ways the ſeed is come at without difficulty, as I have tried with good ſucceſs, though ſome have been apt to ſuſpect that the ſeeds of cones opened by the heat of an oven would be too much dried to vegetate. When the ſeeds are well cleaned, ſow them thin in beds, covering them about half an inch deep with fine earth, and in a month's time they come up. Take care at their firſt appearance to preſerve them from ſnails, which are their greateſt enemies. The ſame ſummer they ſhoot hardly more than an inch, and as their roots lie very near the ſurface, it is adviſable to ſift ſand over the beds near half an inch thick about ſeptember, to keep them ſteady, and prevent the froſts from turning them out of the ground. The ſecond year they will be about four inches high, and if they were to remain a third year they would be near a foot taller; but it is beſt to remove them at two years old, and even then it ſhould be done with care, removing them to the plantation in a barrow of earth, and not taking them out till the very inſtant, if poſſible, that they are to be planted,

[n] Hunter in Evelyn's Silva.

for a little air dries and ſhrinks the roots. Set them not more than ſix feet apart, that they may grow ſtraight and tall, unleſs you would run the hazard of tranſplanting ſome of them a ſecond time, and then the diſtance between them need not be above three feet; they might remain thus ſide or ſix years, and then it would be high time to draw every other tree to make room for the reſt. The method practiſed by James Johnſton, of Twickenham, Eſq. for removing large Firs above twenty feet high, was about mid-ſummer to plant them in a preparation of earth and water, of the conſiſtency of a thin mud, filling up the hole gradually with fine earth, till the roots of the trees were firmly ſettled in it: by which means they made ſhoots above a foot long the following year, before the others which remained in the nurſery began to ſhoot[a].

To raiſe plantations of Scotch Fir, let the cones be gathered in February or march, from thriving young trees: expoſe them to the heat of the ſun, thinly ſpread on coarſe canvas, taking them under cover in the night, and only expoſing them when the ſun ſhines. When any quantity of the ſeed is ſhed, ſeparate it from the cones; otherwiſe the firſt-dropped ſeeds would become too dry. The ſowing muſt be finiſhed the end of april or beginning of may; ſo that if the cones will not yield their contents to the ſun, they muſt be gently kiln-dried. A light loamy ſoil, trenched a foot and a half deep, and laid out in beds five feet broad, anſwers beſt for ſowing. Let the ſeeds be ſown very thick, and covered with a thick ſifting of mould from the alleys. The plants will thus riſe like a bruſh, and a good crop will have above a thouſand in every foot of the beds, that is in five ſquare feet. No manure ſhould be given them, to avoid introducing of weeds, the drawing of which brings up many of the tender plants, and by looſening the ground lets in both froſt and drought. When they have the growth of two ſeaſons, plant them out irregularly from the ſeed-bed, three feet aſunder, upon the grounds where they are to riſe to perfection; planting the drieſt ground in autumn, eighteen months after ſowing, and continuing till froſt ſets in. Begin again in february, or rather as the weather admits, and continue the work, if neceſſary, to the end of april. It is beſt to plant thus from the ſeed-bed, for when they are removed into the nurſery, the roots muſt be pruned conſiderably before they can be planted where they are to continue, which adds greatly to the expenſe; and nurſing cauſes a luxuriant growth in this hardy mountainous tree, which ſpoils its nature, and robs it of longevity. The trees which grow ſpontaneouſly from ſeed, come up very cloſe, and grow very ſlow; for theſe reaſons they are taller, leſs knotty, and of a cloſer harder grain than planted trees, which are uſually ſet in a richer ſoil, and allowed more room. James Farquharſon, Eſq. who has planted ſeveral millions of Scotch Firs, has obſerved in a ſelf-ſown tree of two feet and a half diameter, which is near the ſize of a planted Fir fifty years old, 214 circles, which makes this natural Fir above four times the age of the planted one[a].

Mr. Boutcher directs the cones to be gathered or picked up in march or april, and kept in a dry place till the hotteſt weather, when they ſhould be treated as he has directed for the Larch; and kept in boxes or bags, in a dry room, till the ſeaſon of ſowing: which ſhould be the middle of march or as ſoon after as the land is dry, and the weather favourable, in ſhady borders of generous looſe mould at the rate of a pound of good ſeed to a bed ſixty feet long by three feet and a half broad; covering them a quarter of an inch thick. As the plants begin to appear water them in the morning every four or five days for five or ſix weeks, if the weather be dry without froſt.

From the beginning to the middle of april following tranſplant them from the ſeed-bed in rows fifteen inches aſunder, and ſix or ſeven inches in the row, giving them three or four plentiful waterings if the weather require it. Let them remain two years, and they will be fit to encounter all difficulties, and to ſucceed in the worſt ſoils and coldeſt ſituations.

For the purpoſe of immediate ſhelter they may be removed once more into rows three feet aſunder and eighteen inches in the row, to ſtand two years longer.

In all the removals, have by you a tub of water and earth, mixed to ſuch a conſiſtence as that a conſiderable quantity will adhere to the roots of the plants. As ſoon as they are taken up, let them be plunged in the tub as deep as they ſtood in the ground; and if they continue ſeveral hours in this ſituation, it will be ſo much the better[b].

No Fir tree ſhould ever be pruned, unleſs it be cutting off the branches near the ground: when this tree is in old age, the branches gradually decay from the root to the top. The time for cutting it down is when all the limbs are dead, but the top branches quite healthy. The timber is better when the branches drop from age; and there is no knot or blemiſh in the wood. If a Fir tree in vigour be much pruned, it is reduced to a ſtate of old age.

The improvements that have been made in the northern parts of Scotland by means of large plantations of Scotch Pine, upon the bareſt moors, and in the bleakeſt and moſt inhoſpitable ſituations are well known. The returns of theſe plantations have been ſuch as fully to ſatisfy the owners. But when the collateral advantages are adverted to, the improvements are very great indeed: for in the neighbourhood of ſuch plantations, houſes can be reared at ſo little expenſe, and the roofs are ſo much better than ordinary, as to induce ſettlers to make their dwellings much neater and more commodious than in other places; rails and other dead fences can be ſo eaſily obtained, that poor people are firſt enabled to have good well-fenced gardens, and then commodious incloſures of larger extent; the branches afford fuel to the ſettlers; cutting and manufacturing the wood furniſhes employment to many; population is thereby augmented; hence a deſire for land to produce the neceſſaries of life, and a conſequent increaſe of rent to the proprietor. In this way, Mr. George Dempſter ſees fields rapidly converting into cultivated grounds on his eſtate, and yielding to him ten or twelve ſhillings an acre rent, not only without any expenſe to him, but after having derived a conſiderable profit from the ſale of woods of his own planting, which grew upon land that five and twenty years before was not worth, to him, above two-pence an acre, and which might have remained in that ſtate for ages to come, had it not been planted.

A plantation of Scotch Pine can be made at much leſs expenſe than any other tree in the northern parts of Scotland, becauſe the young plants can be afforded at a ſmaller price. In Aberdeenſhire plants of two years old, and above that age no experienced planter will ever buy them, ſometimes ſell at four-pence the thouſand, conſiſting of 1200; and they ſeldom exceed eight-pence: and there are men who will undertake to complete the whole incloſing, and planting at the diſtance of a yard from each other, and ſupply the deficiences for five years, at the rate of from ten ſhillings to thirty ſhillings the Scotch acre[a], according to the ſize of the incloſure, and the nature of the fence.

It is found by experience, that there is ſcarcely any ſoil ſo bad, or any expoſure ſo bleak, where this tree will not live, if the plantation be of ſufficient extent, and not upon the very ſummit of high peaked hills. They do not indeed bear the ſea air very well; nor is the wood ever of a good quality, or the tree long lived upon clayey ſoils. Several perſons in the South of England have found that the Pinaſter bears the ſea blaſt much better than any of the other Pines. The Spruce Fir will bear a ſtill more expoſed ſituation than the Scotch Pine, and after a few years it ſhoots up with ſtill greater luxuriance. But the cones not being to be had in equal abundance, and the plants being more difficult to rear, they are ſold at a much higher price. Silver Fir, in a good ſoil, proſpers well, and is a beau-

[a] Philoſoph. account of the Works of Nature, 1721. p. 17
[a] Hunter's additions to Evelyn.

[b] Boutcher.
[a] Four Scotch acres are nearly equal to five Engliſh acres.

tiful tree, but the price of the plants is too great to admit of large plantations of them being made.

Where the ſituation is bleak, and much expoſed to ſtrong blaſts of wind, the plantation muſt not only be of conſiderable extent, but the trees muſt be planted very cloſe, ſo as to be not more than from two to three feet aſunder: the more expoſed the ſituation the cloſer they muſt be; for it is obſerved that until the branches intermingle and thus ſerve to give a mutual ſupport to each other, the trees never begin to advance with vigour. Where the plantations are thus thick, there is a neceſſity for beginning to thin them out from the tenth to the fifteenth year after planting. Where the plantations are extenſive, theſe thinnings ſell at a ſmall price, but there are few ſituations in which they will not do more than pay for the expenſe of cutting them out.

The leaves and branches of the Scotch Pine afford a very wholeſome nouriſhment to cattle and ſheep. In mountainous countries, where ſnow ſometimes lies upon the ground for many weeks together, the benefit that may occaſionally be derived from ſuch plantations will be very great: and the larger branches that are left make excellent fire-wood[r].

The ſeeds of Pines are better extracted from the cones, by laying them in the ſun than by the fire. The application of too great a heat will injure or deſtroy vegetation in them; and the practice of laying the cones on the floor of a malt-kiln, which is ſaid to be uſed by ſeedſmen, will account for the badneſs of ſeed purchaſed from wholeſale dealers. It may alſo be too old, for the ſeeds of Pines and Firs ſhould be ſown as ſoon as poſſible after they are taken from the cones.

Mr. Miller has affirmed, that the ſeeds, kept in the cones, will grow at ſeven or even ten or twelve years old. Mr. Hanbury, and Mr. Marſhall from him, call this a very great and dangerous miſtake, at leaſt as applied to the Stone Pine, for the ſeeds of this ſort, whether kept in the cones or taken out, are never good after the firſt year. This may probably be right; but Mr. Miller's affirmation is of Pines in general, not of the Stone Pine in particular; and Mr. Miller himſelf confirms theſe gentlemen's correction in ſome meaſure, by ſaying that he had frequently received the ſeeds of a Pine from China, ſo like thoſe of the Stone Pine, as not to be diſtinguiſhed from them; but that being taken out of the cones, they never grew.]

Firs.

The Firs are propagated by ſeeds, in the ſame manner with the Pines. A gentle heat will ſerve to extract the ſeeds of theſe, becauſe their cones open much eaſier than thoſe of the Pines, eſpecially the Silver and Balm of Gilead Firs, which, if permitted to hang late in the autumn, fall to pieces and ſcatter their ſeeds. It is beſt however to preſerve the ſeeds in the cones till the time of ſowing, which is the end of march or beginning of april; according to the ſeaſon; in a north or north-eaſt border; covering the ſeeds about half an inch deep with the ſame light mould in which they are ſowed; and netting the beds to keep off the birds. In theſe beds the plants ſhould remain until the following ſpring, when there ſhould be a number of beds prepared in the nurſery to receive the ſeedlings. In the beginning of april they ſhould be tranſplanted into the beds, at the diſtance of ſix inches row from row, and in the rows at three inches aſunder, ſetting them in a quincunx order. In removing theſe plants, they ſhould be very carefully raiſed up with a trowel, ſo as not to break off the fibres of the roots; nor ſhould they be kept long out of the ground. During the time they are out, their roots ſhould be covered, to prevent the wind from drying their fibres; and in planting, the earth ſhould be preſſed cloſe to their roots, to prevent the air from penetrating to them.

If the ſeaſon prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; the beds ſhould alſo be covered with mats, to ſcreen the plants from the ſun, and drying winds, until they have taken good root; after which time they will require little farther care, than to keep them clean from weeds. In theſe beds the plants may remain two years, at the end of which they ſhould be tranſplanted into an open ſpot of ground, for their roots will in that time meet quite over the beds. This ground, to which they are to be removed, ſhould be well trenched and cleared from all noxious weeds, and made level. The beginning of april, juſt before the plants begin to ſhoot, will be a good time to remove them. In taking up the plants, great care ſhould be taken not to tear off or injure their roots; nor ſhould too many of the plants be taken up at one time, but rather plant them as faſt as they are taken up, that they may be as little time out of the ground as poſſible. For the drying winds, which uſually happen at this ſeaſon, will greatly injure the roots of theſe plants, if much expoſed thereto.

The diſtance at which they ſhould be placed in the nurſery, ſhould be four feet row from row, and in the rows two feet aſunder. This diſtance may by ſome be thought too great; but let it be conſidered how much their roots ſpread in the ground, as alſo that when they are planted nearer together, it will be very difficult to take up the plants again without cutting and tearing off their roots, eſpecially if they are not all taken up clean at the ſame time: theſe conſiderations muſt have greater weight than that of the loſs of a little ground, with all who have any regard to the future welfare of the plants. In planting them, it will be adviſeable to draw a line croſs the ground, and to dig out a trench of a foot wide, into which the plants may be placed at the diſtance of two feet aſunder. Then fill the earth into the trench, covering the roots of the plants with the fineſt part of it, ſcattering it carefully between the roots; and when the whole trench is filled in, preſs the earth gently down with your feet; but by no means tread it too hard, eſpecially if the ground be ſtrong, or apt to bind too cloſe.

When the plants are thus planted, if the ſeaſon ſhould prove dry, they ought to be watered, in order to ſettle the earth to their roots; and if this be repeated three or four times, (if the ſeaſon ſhould continue dry) it will greatly promote their taking new root, and ſecure them from the injuries of the drying winds. In this nurſery the plants may remain two or three years, according to the progreſs they ſhall have made; and during this time, the ground between the plants ſhould be conſtantly kept clean from weeds, and dug between the rows every ſpring; in doing of which, care muſt be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nurſery. When they are tranſplanted into the places where they are to remain, the neceſſary care to be taken is, in taking them up, not to injure or cut off their roots, and to let them be as little time out of the ground as poſſible; and while they are out, to guard their roots from the drying winds. The fureſt time for removing theſe trees is about the beginning of april; for though they may be, and often are, removed with ſucceſs at Michaelmas, yet the ſpring is the more ſure ſeaſon, eſpecially in moiſt land.

Moſt of the kinds of Firs may be removed at the height of ſix or ſeven feet; but thoſe of two feet high are much better to tranſplant, and will in a few years gain the aſcendant of taller trees: I would not, therefore, adviſe the tranſplanting of theſe trees when they are much above two feet high, eſpecially if they have ſtood in the nurſery unremoved. For then their roots will have extended themſelves to a diſtance, and muſt be cut in taking them out of the ground; and where great amputation is uſed either to the roots or branches of theſe trees, the quantity of turpentine which commonly iſſues from theſe wounds, will greatly weaken the trees. There is another advantage alſo in planting them when ſmall, which is that of not requiring ſtaking to ſecure them from being blown down by ſtrong winds, which in tall trees is a great trouble and expenſe. And whoever will give themſelves the trouble to obſerve, how much trees of two feet high exceed

[r] Anderſon's Eſſays, vol. 3. 358. &c.

exceed in growth thoſe which are removed at a much greater height, will, I am ſure, be convinced of the truth of what is here ſaid.

The common Spruce Fir is what affords the white deals. The trees grow in the deep ſtrong ſoils of Norway and Denmark; but will grow likewiſe in almoſt any ſoil or ſituation in England, provided it be not within the reach of the ſmoke of great cities, which is very injurious to all theſe ſorts of trees; nor do they thrive near ſo well in dunged land, as in freſh uncultivated ſoils. The diſrepute theſe trees have been under for ſome years paſt, has been occaſioned by their being planted too cloſe together, or too near other trees, whereby the air has been excluded from their branches, which has occaſioned moſt of their under branches to decay; ſo that when viewed from the ground under their branches, they have a greater appearance of dead than living trees. But where they have been allowed a good diſtance, and planted in a ſtrong freſh ſoil, they have had their branches quite feathered within ſix or eight feet of the ground, and that too in trees upwards of ſixty feet high; therefore they ſhould not be planted nearer than twelve feet apart, nor ſhould they be ſo near, where the plantation is more than three rows deep. In this caſe, eighteen or twenty feet aſunder will be full near enough, eſpecially where the trees are deſigned to have their branches feathered near the ground, in which one of the beauties of theſe trees conſiſts.

The Silver Fir requires a ſtronger land than the Spruce, for in dry ground they ſeldom make any great progreſs; and many times, even after they have arrived to a conſiderable ſize, are deſtroyed by very dry ſeaſons, where the ſoil is ſhallow, or too dry. But when they are planted in a proper ſoil, they grow to a very large ſize, and are extremely beautiful, having the under ſide of their leaves white, and the upper ſide of a dark green colour.

This ſort of Fir, however, is frequently injured by froſts, when they happen late in the ſpring, eſpecially while the plants are young. For when theſe are planted in a warm ſituation, they are apt to ſhoot pretty early, and if any ſharp froſts happen after they have puſhed, the young ſhoots are killed; ſo that they loſe a year's growth, and are rendered ſo very unſightly, that many times they have been pulled up and thrown away. In cold ſituations, however, where they do not begin to ſhoot ſo early, they are not ſubject to this diſaſter; and, in many ſuch places, theſe trees grow to a large ſize, and have their beauty. I have ſometimes ſeen ſome fine trees of this ſort of Fir, which grew upon natural bogs, where, by extending their roots, they had drained the ground to a conſiderable diſtance round them.

The method of raiſing the other ſort of Firs.

About the latter end of march, or the beginning of april (according to the forwardneſs of the ſeaſon, by which every perſon muſt be guided) prepare a very moderate bed, in length proportional to the quantity of ſeeds to be ſown, and where there are frames which can be ſpared for this purpoſe, theſe may be placed upon the bed; but where theſe are wanting, the bed ſhould be cradled over with hoops, that they may be covered with mats or canvaſs; then plunge the bed full of ſmall pots, ſuch as are commonly ſold about London for four ſhillings and two pence per hundred. Theſe pots ſhould be filled with light undunged earth, and the interſtices between the pots may be filled up with any other earth which is neareſt to the place; then ſow the ſeeds in theſe pots, covering them about half an inch with the ſame light earth. In drying winds the bed ſhould be covered, to prevent the earth from drying too faſt, which would prove hurtful to the ſeeds; nor ſhould the ſeeds have too much wet, which would be equally injurious to them: therefore the earth ſhould be but ſeldom watered, and it muſt never be given in great quantities. When there is any appearance of froſt at night, the bed ſhould alſo be covered. With this management the plants will appear in five or ſix weeks time, when they muſt be carefully guarded from birds as was before directed for the common ſorts, and alſo ſcreened from the ſun in the middle of the day; but they muſt now have freſh air admitted to them at all times when the weather will permit. They may alſo be allowed to receive any gentle ſhowers of rain, but they ſhould not have too great plenty of moiſture, which will frequently rot the young plants, and cauſe them to drop. Upon the judicious care of this, depends the whole ſucceſs; for I have frequently ſeen great numbers of theſe plants deſtroyed in one day, by being either too much expoſed to the ſun, or from having too much wet.

It may, perhaps, ſeem ſtrange to many, that I ſhould direct the ſowing the ſeeds of theſe trees which are ſo very hardy upon a hot-bed; but from many trials I have always found they have ſucceeded much better this way than any other, for the gentle warmth of the bed will not only cauſe the ſeeds to vegetate much ſooner than they would naturally do in the cold ground, but the plants will alſo riſe much ſtronger, and, conſequently, be in leſs danger of rotting in their ſhanks. And as the warmth of the bed is only to bring up the plants, ſo there ſhould be but little dung employed in making it; for after the plants are up, they muſt be inured to the open air, and treated as hardily as the common ſorts.

There may be others, perhaps, who will object to the directions given for ſowing the ſeeds in ſuch ſmall pots, becauſe, where there is any quantity of the ſeeds, it is uſual to ſow them in boxes, or large pots: but I can from many years experience aver, that moſt ſorts of ſeeds ſucceed better when ſown in ſmall pots, than in boxes, or larger ones, and therefore recommend this practice.

As the ſeeds of the Hemlock Fir will frequently remain in the ground four or five months, the pots, in which they are ſown, ſhould not be diſturbed, if the plants come not up ſo ſoon as may be expected; for unleſs upon ſtirring the ground, the ſeeds are found to be decayed, there may be hopes of their growing the ſecond ſpring, for I have ſometimes had the ſeeds remain a whole year in the ground, and afterwards come up very well: this caution, therefore, is given to prevent the pots from being too haſtily turned out.

The plants of theſe ſorts of Fir muſt be afterwards treated in the ſame way as the common ſorts with this difference only, that they ought to be tranſplanted into a more ſhady ſituation and moiſter ſoil. For while the plants are young, they will not thrive if they are much expoſed to the ſun, or in a dry ſoil; but when they have obtained ſtrength, they will bear the open ſun very well, and in a moiſt ſoil will make great progreſs; whereas in dry ground they frequently ſtint, and produce plenty of male flowers and cones, by the time they get to the height of four or five feet. When the branches of theſe trees are cut off to trim them up to have ſtems, it ſhould be done gradually, never cutting more than one tier of branches in one year; for if too many wounds are made at the ſame time on theſe reſinous trees, the turpentine will iſſue out in ſuch quantities as to weaken and check their growth. The beſt time for pruning theſe trees is in ſeptember, at which time they abound not ſo much in turpentine as in the ſpring, and, conſequently, do not bleed much. What flows out at that ſeaſon, is ſeldom more than is neceſſary for covering the wounds, to prevent the wet and cold of the ſucceeding winter from penetrating the wounded parts. Theſe branches ſhould be cut cloſe to the trunk.

[In ſowing all ſorts of Firs, neglect not to clap over the beds with the back of a ſpade. In the autumn after ſowing pick off all moſſy hard particles from the beds, replacing them with ſome good ſoil, and then ſifting over ſome chaff, or rather ſaw-duſt, that has lain ſome time. The ſucceeding ſpring, and during may and june, water them frequently, and in autumn treat the beds as before. At two years old, when the buds begin to ſwell, remove them from the ſeed-bed.

The Balm of Gilead and Hemlock Spruce ſhould have the beds hooped over, to be covered with mats for five or ſix weeks after the plants appear above ground, when the ſun is hot, or the air cold or froſty:

they ſhould be watered every ſecond evening, when it does not rain.

The Balm of Gilead Fir requires a good deep ſoil, and a ſheltered ſituation.

It is in vain to plant the Silver Fir in hot dry or rocky ſituations, where it commonly loſes the top ſhoots, and the under branches ſoon become ragged. The largeſt and moſt flouriſhing trees are ſeen on four heavy obſtinate clay, and though for ten or twelve years they do not advance ſo faſt as ſeveral other Firs and Pines, yet in twenty they will outgrow them all. They ſhould not be too cloſe, but require a free circulation of air*.

According to Mr. Boutcher's opinion though ſpring be the proper ſeaſon for planting ſeedling Firs and Pines, yet the beſt time for tranſplanting all the hardy ſorts, which have arrived to a foot in height or upwards, is the month of auguſt, as ſoon as they have perfected their ſhoots. Mr. Hanbury recommends July.

For plantations of timber, where the land can be got in order for it, the beſt method certainly is to ſow the ſeeds on the ground where they are to continue; but if this cannot be done, the plant ſhould be finally ſet out from the ſeminary at two years old: in rough grounds overrun with heath, &c. ſuch ſmall plants would be loſt; they muſt be removed from the ſeminary into a nurſery, and not finally planted out till they are of a ſize to overtop the heath and graſs.

For ornamental plantations it may be ſometimes deſirable to plant out much larger. For this Mr. Boutcher gives the following directions.

In order to remove Firs or Pines eight or ten feet high with ſucceſs, at four years old tranſplant them to another ſpot of good land, in rows two feet and a half aſunder, and fourteen or ſixteen inches diſtant plant from plant. Water them at planting, and continue it once a week five or ſix times when it does not rain: keep the ground clean, dig it ſpring and autumn, and let the plants remain three years. Then remove them in ſpring, ſhortening their ſtraggling roots moderately, and plant them in rows four feet aſunder, and two feet in the row, to remain three years longer. If required larger, remove them again, at ſix feet aſunder every way, to remain two, or not more than three years; by which time, in good land, the Norway, Black and White American Spruces will be from fourteen to ſixteen, and the Silver Firs from ten to twelve feet high. Thus managed, they will riſe with ſuch large balls of earth, as will prevent their receiving the leaſt injury at removal. Theſe and other large evergreens require more frequent, though gentler waterings, than deciduous trees, and ſhould have no branches taken off at this time.]

Cedar of Lebanon.

The cones of this tree are frequently brought from the Levant, and we have them now of our own growth. If they are preſerved entire, the ſeeds will keep good in them ſeveral years: the time of their ripening is commonly in the ſpring, and thoſe which come from abroad are near one year old before we receive them; for which they are not the worſe, but rather the better; the cones having diſcharged a great part of their reſin by lying, and the ſeeds are much eaſier to get out of them than ſuch as are freſh taken from the tree.

The beſt way to get the ſeeds out is to ſplit the cones, by driving a ſharp piece of iron through the center lengthways, then with your fingers you may pull out the ſeeds, which you will find faſtened to a thin leafy ſubſtance as are thoſe of the Fir-tree: but before the ſeeds are taken out, it will be proper to put the cones in water for twenty-four or thirty hours, which will render them eaſier to ſplit, ſo that the ſeeds may be taken out with greater facility; for there will require care in doing of it, otherwiſe many of the ſeeds will be ſpoiled, as they are very tender, and will bruiſe where there is any force employed to get them out.

[This will be beſt accompliſhed by thruſting a wooden peg down the hole, rather bigger than the iron one, after the cones have been ſoaked. The ſame method may be uſed for extracting the ſeeds out of the Stone Pine.]

Theſe ſeeds ſhould be ſown in boxes or pots of light freſh earth in march, and treated as was directed for the Firs, only theſe require more ſhade in ſummer while young than the Firs, and ſhould be frequently refreſhed with water.

When the plants come up, which will be in ſeven or eight weeks, they muſt be guarded from the birds, otherwiſe they will pick off their tops, as they do of the young Firs where they are not guarded; they muſt alſo be conſtantly kept clean from weeds, and not placed under the drip of trees. The plants may remain in theſe boxes or pots in which they were ſown till the following ſpring, but it will be proper to place them under a frame in winter, or cover them with mats, if the ſeaſon proves very ſevere; for while they are young they are in danger of loſing their tops, if they are pinched by froſt, for the young plants often ſhoot late in the autumn. In april before the plants begin to ſhoot, they ſhould be carefully taken up and tranſplanted into beds at about four inches diſtance, cloſing the earth gently to their roots; theſe beds ſhould be arched over with hoops, and covered with mats in the heat of the day, to ſhade the plants from the ſun till they have taken new root; and if the nights prove froſty, it will be proper to keep the mats over them in the night, but in cloudy or moiſt weather they muſt be always open. After the plants are well rooted, they will require no other care but to keep them clean from weeds, unleſs the ſeaſon ſhould prove very dry, in which caſe it will be proper to give them ſome water once or twice a week; but it muſt be but in ſmall quantities, for too much wet is often very injurious to them; ſo that it will be better to ſcreen them from the ſun in hot weather, to prevent the earth from drying too faſt, or cover the ſurface of the ground with moſs to keep it cool, than to water the plants often.

In theſe beds the plants may ſtand two years, then in the ſpring they ſhould be either tranſplanted to the places where they are deſigned to remain, or to a nurſery where they may grow two years more; but the younger theſe trees are when they are planted out for good, the better the trees will thrive, and the longer they will continue.

When theſe plants begin to ſhoot ſtrong, you will generally find the leading ſhoot incline to one ſide; therefore, if you intend to have them ſtraight, you muſt ſupport them with ſtakes, obſerving to keep the leader always cloſe tied up, until you have got them to the height you deſign them, otherwiſe their branches will extend on every ſide, and prevent their growing tall.

Theſe trees were formerly kept in pyramids, and ſheared as Yews, &c. in which form they loſe their greateſt beauty; for the extenſion of the branches is very ſingular in this tree, their ſhoots for the moſt part are declining, and thereby ſhewing their upper ſurface, which is conſtantly clothed with green leaves in ſo regular a manner, as to appear at ſome diſtance like a green carpet; and theſe waving about with the wind, make a moſt agreeable appearance at a diſtance, eſpecially if planted on a riſing ground.

[During the time they are in the nurſery, and after planting out, many will frequently have a tendency to droop in their leading ſhoot; as ſoon therefore as this is perceived, an upright ſtake muſt be driven into the ground, to which the ſhoots ſhould be tied with baſs matting to keep them in their upright growth. This however will not always effect it, for ſome plants in ſpite of the bandage, will ſhoot downwards. In this caſe, when they firſt diſcover ſigns of ſuch a tendency, it will not be amiſs to lighten the head, by nipping off the extremities of ſome few of the largeſt branches.

When theſe trees are planted out to remain, they ſhould be left to nature, after being properly fenced: not a knife nor a hatchet ſhould come near them: lopping even their loweſt branches is ſo injurious, that

* Boutcher.

it both retards their growth and diminiſhes their beauty[1].]

THE LARCH.

The common Larch is now very plenty in moſt of the nurſeries in England, and of late years there has been great numbers of the trees planted; but thoſe which have been planted in the worſt ſoil and in bad ſituations, have thriven the beſt; for where trees of equal ſize have been planted in good garden earth at the ſame time, the others on the cold ſtiff land, have in twelve years been twice the height of thoſe planted in good ground; which is an encouragement to plant theſe trees, ſince they will thrive in the moſt expoſed ſituations, provided they are planted in clumps near each other, and not ſingle trees; nor ſhould the plants which are planted in very open expoſed places be taken from warm nurſeries, but rather raiſed as near to the ſpot where they are to remain as poſſible; nor ſhould the plants be more than three or four years growth when planted, where they are deſigned to grow large: for though trees of greater ſize will remove very well, and grow ſeveral years as well as if they had not been tranſplanted; yet after twenty or thirty years growth they will frequently fail, where the young planted trees have continued very vigorous.

Theſe trees are raiſed from ſeeds, which moſt years ripen well in England: the cones ſhould be gathered about the end of november, and kept in a dry place till the ſpring, when they ſhould be ſpread on a cloth and expoſed to the ſun, or laid before a fire, which will cauſe the ſcales of the cones to open and emit their ſeeds. Theſe ſeeds ſhould be ſown on a border expoſed to the eaſt, where the morning ſun only comes on it: or if they are ſown on a bed more expoſed to the ſun, they ſhould be ſcreened with mats from the ſun in the middle of the day; for when the plants firſt appear above ground, they are very impatient of heat; and when the bed is much expoſed to the ſun, the ſurface of the ground will dry ſo faſt, as to require to have water very often, which frequently rots the tender ſtems of the plants; which will be prevented by properly ſhading them while young, and afterwards they will be in no danger. Theſe young plants ſhould be conſtantly kept clean from weeds, and if they have made good progreſs, they may be tranſplanted the following autumn, otherwiſe they may remain in the ſeed-bed another year, eſpecially if the plants are not too cloſe together. When they are tranſplanted, it ſhould be performed in the autumn as ſoon as their leaves decay; they may be planted in beds at about ſix inches aſunder each way, which will be diſtance enough for the growth of the plants the two following years, by which time they will be fit to tranſplant where they are to remain.

When the young trees are planted out for good, they need not be more than eight or ten feet diſtant from each other, always planting them cloſer on expoſed ſituations, than where they are more defended; after the trees are planted, they will require no other care but to keep them clean from weeds for three or four years till the trees have obtained ſtrength, when they will over-top the weeds and prevent their growth; but the ground between theſe trees ſhould not be dug, for that I have found has greatly ſtopped their growth.

The Siberian Larch is of ſlow growth in this country, for when the ſpring is mild, the trees will begin to ſhoot in february, or early in march; and there are frequently ſharp froſts after, whereby theſe ſhoots are often killed, and this ſtops the growth of the trees. Likewiſe when they are planted on a warm dry ſoil, they are frequently killed by drought in the ſummer; therefore this is a very improper tree for this country, unleſs for ſome cold, moiſt, peaty land, where they may probably thrive, and in ſuch ſituations few other trees will grow.

The American or Black Larch, thrives pretty well upon moiſt land, but on dry ground will make but little progreſs. A few of theſe trees by way of variety, may be allowed to have place in every collection of trees deſigned for pleaſure; but for profit, the common Larch is to be preferred to any other ſpecies.

This is a very proper tree for planting on cold barren hills, which in their preſent ſtate produce little or nothing to the proprietors, and in one age may be large eſtates to their poſterity, beſides a great national advantage. This might be effected at no great expenſe, if properly conducted.

The beſt method for doing this, would be by making ſmall nurſeries or ſeminaries at or near the place where the plantation is intended to be made. In theſe nurſeries the ſeeds ſhould be ſown; and if there are any poor cottagers, they may be employed in raiſing the plants, keeping them clean, and tranſplanting them. This will aſſiſt the poor, and by employing them in this buſineſs, they may be brought to have a regard for trees of their own planting: and as the ſeaſon for doing this, is at a time when farmers have little employment for their labourers, it is an advantage to all parties; and children may be taught to weed the young plants, and thus rendered uſeful, inſtead of being burdenſome to pariſhes.

[Though the cones of the Larch be of their full ſize in autumn, yet the ſeeds continue ripening all the winter; they ſhould not be gathered therefore till march or april. Spread them in dry covered places till may or june, and then expoſe them to the full ſun for ſeveral weeks, when the cones will open, and many of the beſt ſeeds come out, by ſhaking them in a wire ſieve: to get out the reſt, ſplit the cones, by driving a ſmall piece of ſharp iron through the centre, and then by expoſing them again to the ſun for a few days, the ſeeds will ſhake out, or may eaſily be picked out with the point of a knife. Though the ſeeds in the cone are good for four or five years, yet out of it they loſe their vegetating quality in a few months; therefore as ſoon as they are got out, mix them with fine dry ſand, and keep them in bags till the ſeaſon of ſowing, which is the beginning of march, or as ſoon after as the weather will permit. Sow them very thin, in beds three feet and a half broad, with alleys of eighteen inches; clap them gently in with the back of a ſpade, and ſift over them fine compoſt earth, with one fourth ſea-ſand or pit-ſand. If the weather is dry and not froſty, in a fortnight after ſowing, give them gentle waterings every fourth or fifth day, and in ſix weeks they will begin to appear. Guard them from the birds with nets, and water them every ſecond or third night for three weeks very gently: continue this once in ten or twelve days to the end of auguſt.

The end of march or beginning of april following remove them from the ſeed-bed to the nurſery, in rows fifteen inches diſtant, and ſix or ſeven inches aſunder; watering them at planting, and once a week for five or ſix weeks after.

At the ſame time in the ſucceeding year remove them to another nurſery, in rows three feet diſtant, and fifteen or ſixteen inches in the row: here let them remain two years; by this time they will be five or ſix feet high, and of a proper ſize to tranſplant in expoſed ſituations, on meagre hungry ground*.

Dr. Hunter directs, that juſt before ſowing, the cones ſhould be opened or torn into quarters by a knife, the point of which muſt be thruſt exactly down the centre, that the ſeeds may not be damaged: they ſhould then be threſhed in a room. Three thouſand cones will generally produce a pound of good ſeeds: theſe being winnowed or ſieved will be ready to ſow in april.

Or, the ſcales of the cones being ſo glued together, that they are ſeparated with difficulty without bruiſing the ſeeds; let them be laid in heaps ſix inches thick, in a ſhady but expoſed ſituation, till the beginning of may. Then let beds four feet in breadth be prepared, newly dug; let the mould be raked to the ſides, ſo as to form a kind of ridge, to prevent the cones from falling into the alleys, which ſhould be two feet wide for the convenience of the weeders. Cover theſe beds entirely with the cones, and if the weather comes

[1] Marſhall on planting, edit. 2. vol. 2. 260.

* Boutcher.

warm and dry, they will preſently expand, and ſhed the ſeeds. When a ſufficient quantity is ſhed, remove the cones to a ſecond bed, firſt giving them a ſhake in a coarſe ſieve, which will cauſe a conſiderable quantity of ſeed to fall, eſpecially if it be done in the middle of the day: then ſift fine mould, a quarter of an inch thick, over the whole bed. If the weather ſhould be dry, they muſt be gently watered, and the beds kept clear of weeds. The cones may be removed to a third, and even a fourth bed. The times for laying on the cones depends on the dryneſs and warmth of the weather. The ſeeds ſhould come up thick, or elſe they will be apt to be thrown out of the ground by the froſt.

The following ſpring prick them out in beds three inches aſunder: and the ſecond ſpring plant them in the nurſery in rows three feet aſunder, and eighteen inches in the rows. Hence they may be planted out finally the ſecond or third year after. But as thoſe trees always thrive beſt that are removed ſmall, they ſhould be planted out as ſoon as they are of a ſufficient ſize not to be injured by weeds*.

Dr. Anderſon, who endeavoured five and twenty years ſince to turn the attention of his countrymen in Scotland towards this uſeful tree, is of opinion that it ſhould be planted entirely by itſelf, becauſe ſoon outgrowing moſt other trees, where the Larches are thinly ſcattered, they are expoſed to the wind, and their tender top-ſhoots are apt to be damaged. He recommends therefore that the Larch ſhould be made to ſhelter itſelf, by planting very thick, even ſo near as two feet. In a plantation made at this diſtance, the trees have ſhot up with great rapidity, ſtraight, clean, and healthy.

His theory is this. It has been often remarked, that no wood of the Fir kind, raiſed in artificial plantations, ever equals in quality that which is produced ſpontaneouſly: the natural wood being cloſer in the grain, harder and deeper in colour, with fewer knots in it. The reaſon is, that in natural woods of Larch and other coniferous trees, the ſeeds being ſtrewed very thick upon the ground, the plants ſpring up very cloſe. Being ſtraitened for room, their growth is ſtinted, and they ſtruggle for ſome years which ſhall get the better. By degrees, the weaker plants are over-topped and die; but ſtill others ſtruggle for life, and maintain the conteſt; and thus it goes on till they have attained a conſiderable height, when the boughs of the moſt vigorous trees, ſpreading out above, overtop all thoſe that are near, and thus a ſufficient ſpace is allowed for theſe to flouriſh till they attain their full ſize.

During this long ſtruggle the growth of the trees is ſlow, and conſequently the fibres of the wood very cloſe and hard. The ſide branches too, having no room to ſpread abroad, are kept weak, and are ſoon ſuffocated, by the winds and rubbing of the trees round them, theſe branches are ſoon broken off, and the bark begins to cloſe over the wound. The ſtem thus becomes clear of branches and ſmooth, and all the wood that afterwards grows over it is free from knots.

In artificial plantations we follow an oppoſite courſe. Anxious to admire the progreſs of our trees, no meaſures are adopted to retard their progreſs at an early period, but rather the reverſe: and were we even inclined to follow nature, the very expenſe of planting ſo many trees on an acre would be a deciſive bar to ſuch enterprizes. The young trees are of courſe planted at a conſiderable diſtance, and are encouraged to grow as quickly as poſſible, and thus the wood is coarſe in the grain and ſoft. The branches too, having room to ſpread, advance with great luxuriance, and continue to grow till they attain a large ſize, and of courſe render the wood full of large knots.

Though we cannot afford to make our plantations ſo thick as nature does, we ought to approach as near as prudence will admit; and by planting Larches at two feet diſtance, the benefit to be derived from the practice will do more than repay all expenſes attending it.

At this diſtance, an Engliſh ſtatute acre will contain 10890 plants. Being planted in rows, the younger the better, the ground laid dry, well-fenced, and no graſs or weeds ſuffered to choak them; in this ſtate they may remain ſix, eight, ten or twelve years, according to the ſoil, or the purpoſes for which the thinnings are wanted; when they ſhould be thinned for the firſt time. This however ought not to be too long delayed, leſt the tops, by growing too cloſe, ſhould be ſo much ſmothered as to occaſion a hurtful gap when the thinnings are taken away.

One row ſhould now be wholly taken out, ſo as to leave the plants four feet apart; and allowing three rows to remain entire, take out the fourth, and ſo on. Thus, though the row on each ſide the opening will loſe its ſupport on one ſide, its branches being ſtill intermixed with thoſe on the three other ſides, will give it ſufficient ſupport. It is neceſſary to cut out a row completely, to admit of trailing out the long ſpires, together with their tops, which could not otherwiſe be done.

In conſequence of this open, the branches above will be permitted to grow more freely, and in this ſtate they ſhould remain till they intermingle again above, when they ſhould receive the ſecond thinning, by taking out the middle row that was left at the former thinning, when the plants will ſtand in the rows four feet apart, and two feet from each other in the rows.

When the branches cloſe again, the third thinning may be given by culling out every fourth row croſswiſe. And the fourth thinning may be given, by taking out the croſs row that was left between the two contiguous to it.

Now the trees in a whole plantation are again reduced to ſquares, ſtanding four feet apart: and there will remain 2722 trees on an acre. So that 8168 trees have been taken out in the ſucceſſive thinnings.

After a proper interval, the trees might be thinned, as above deſcribed, till they are gradually reduced to ſquares at eight feet apart, which is perhaps the greateſt diſtance that ſhould be allowed to trees of this kind. At this diſtance an acre will contain 680 trees.

If then thinnings be begun from the ſix to the tenth year from the time of planting, the whole may be completed thus far by the thirtieth or fortieth year of their growth; during which time there will have been ſold 10210 ſpars from fifteen to fifty feet in height, and proportional thickneſs, from each acre. If it be thought adviſable to continue the thinning farther, after this period, no whole rows ought ever to be cut out any where, but only a ſingle tree here and there.

Now if we ſuppoſe that the ſale of the ſpars would be ſufficient to defray the expenſes of making and upholding the plantation; and that each tree at fifty years growth, inſtead of containing 360 feet of wood, as thoſe at Dunkeld are known to do, ſhould at the ſame age meaſure no more than ſeventy feet each, which is leſs than one-fifth of the others: in that caſe the 680 trees on an acre would contain 47600 cubic feet of timber, which, at 1s. a foot, would be 2380l.; from which, if the rent be deducted at 5s. an acre, which for fifty years is 12l. 10s. and intereſt for payments withheld 14l. 10s. more; there will remain 2353l. clear profit: without taking into the account any advantage from turpentine.

An efficient fence is abſolutely neceſſary for a plantation of Larch, becauſe it is extremely impatient of wounds in its bark. No cattle or ſheep therefore ſhould be admitted, even after the trees have attained a conſiderable ſize.

The nature of the fence muſt be determined by circumſtances. A ſtone wall will be the moſt common, as Larch ought chiefly to be planted on mountainous tracts, and it is the moſt effectual, except againſt light-bodied ſheep, which will readily overleap it, unleſs there is ſome defence of buſhes or a rail on the top of it.

A ditch and bank is by no means an effectual fence againſt ſheep, or even againſt cattle after ſome time, unleſs

* Additions to Evelyn. The laſt is the method practiſed in the Duke of Athole's plantations.

unleſs furze be ſown upon the top of the bank; or in three rows, two of which ſhould be on the ſlope of the bank, cutting one of the rows cloſe every year, to keep it from becoming open at bottom.

When this fence decays, as it will in ten or twelve years, the outer line of Larches being left, will make a fence of themſelves, or at leaſt with the aſſiſtance of the Sweet-briar or Bramble planted between the trees and interwoven with their branches, and a rail from tree to tree where it is wanted [a].

Dr. Watſon, the learned Biſhop of Landaff, who is ever ready to ſtep forward when uſeful ſcience or arts can be promoted, remarks, that the higheſt and moſt craggy mountainous tracts in our iſland, two acres of which do not afford ſufficient ſuſtenance for ſix months in the year to one ſheep, might, with a great proſpect of ſucceſs, be planted with Larches; and he ſtates the probable profit which would attend ſuch plantations.

A thouſand acres of ſuch land might be incloſed with a circular wall ſix feet in height, where the ſtones can be eaſily got, for 6s. an acre, or 300l. for the whole: five hundred larches, two feet in height, ſo as to enable them to reſiſt the long graſs, might be planted on each acre for 14s.; hence a plantation of five hundred thouſand Larches might be made for 1000l. Now this ſum improved at compound intereſt, at the rate of 4l. per cent. would in ſixty years, amount to the ſum of 10519l.; this is the accumulated loſs attending the incloſing and planting one thouſand acres of rocky land in ſixty years. The rent of a thouſand acres, at 1d. an acre is 4l. 3s. 4d. a year; in eight years the Larches would be out of all danger from ſheep, ſo that the loſs of rent ought only to be eſtimated for eight years; but 4l. 3s. 4d. a year, though improved after the ſame rate of compound intereſt, would not amount to 40l. in eight years; ſay however that it would amount to 81l. which is allowing more than 2d. an acre rent, then would the whole expenſe in ſixty years be 1060l. If the amount of 81l. for fifty-two years be taken into conſideration, the expenſe will be 11222l. The ſheep are here ſuppoſed to be ſhut out of the plantation for eight years, if it ſhould be found that ſheep will not crop the Larch, and from more than one obſervation, I have reaſon to believe that they will not, they need not be ſhut out at all; nor on diſtricts, where nothing but ſheep are depaſtured, need any fence be made. The advocates for cloſe planting, inſtead of five hundred, would require five thouſand Larches for each acre; I am not convinced of the utility of ſuch cloſe planting, except where it is intended to nurſe up Oaks, or other kinds of wood; but if that mode ſhould be adopted, the thinnings, after twenty years growth, would pay the expenſe of it. At the expiration of ſixty years, ſuppoſe that only 250 Larches remained on each acre, or that one half had periſhed, the probable value of them may be thus eſtimated. From many experiments made by myſelf, and collected from others, I find the annual increaſe in circumference of the Larch at ſix feet from the ground, to be one inch and a half on an average of ſeveral years; and this inference has been drawn from the actual admeaſurement of Larches in different parts of England and Scotland, and of different ages from ten years old to fifty. On this ſuppoſition, the Larches would meaſure, one with another, ninety inches in circumference, at ſix feet from the ground. Such a Larch would meaſure above ſeventy at twenty feet from the ground, ſuppoſing the length of the tree to be forty feet, neglecting the top; then will its ſolid content be eighty-five cubic feet, and its value, at 9d. a foot, above three guineas. But as the trees are ſuppoſed to be planted in an high, bleak, barren ſituation, their annual increaſe may not be ſo great as is here ſuppoſed; inſtead of being worth, at ſixty years after planting, three guineas apiece, admit that they are worth only 10s. then would the whole plantation be worth 125000l. and deducting the whole expenſe, there would remain a profit of 114400l. The preſent value of this, to be received ſixty years hence, is above 100000l.; intereſt of money at 4l. per cent. and will purchaſe an income, at this rate, of 4000l. a year. By planting then, a barren eſtate of a thouſand acres is improved from 4l. 3s. 4d. to 4000l. a year, reckoning the value of a reverſion as a preſent certainty. Sixty years is a great part of the life of a man; but it ought to be conſidered as nothing in the exiſtence of a nation, or even of a family, which is a little nation. All waſte lands that will not pay for converting into arable or paſture, ought to be covered with wood; the high parts, and eſpecially the ſheltered dells, in the high parts, with Larch; and the lower with Oak, Aſh, &c. Their preſent application to the ſummer-maintenance of a few miſerable ſheep, ought not to be perſevered in, if any other uſe can be made of them [b].

May the reſpectable prelate live to inform the public, whether the actual progreſs of the extenſive plantations which he has made, correſponds with theſe calculations!

E. Harries, Eſq. of Hanwood, recommends an attention to two circumſtances in planting Larches, viz. ſituation and diſtance. The ſtrong weſterly winds are very apt to bend the upper part of the trees, eſpecially if they ſtand ſingle, or upon ſloping grounds. To guard againſt this, he adviſes a ſhelter of Scotch Pines to be planted to the weſtward ſome years before the Larch. The other thing to be obſerved is to give the plants ſufficient room. In eight years they may be about twenty feet high, and their lateral ſhoots extend two yards every way from the trunk; and they ſhould not then be ſuffered to continue nearer than five or ſix yards; and what are left may continue to be uſeful building timber. At firſt planting a diſtance of about ſeven feet ſhould be allowed; they will then be furniſhed with ſufficient lower branches, which give the tree a ſteady and tapering trunk. The knife ſhould never be applied to them. There is no tree of quicker growth. I have Larches that are twenty feet high in ſeven years growth, and ſixteen or eighteen inches round. At thirty years growth they meaſure from four to five feet round, at five feet from the earth [c].

The Rev. Charles Hope, of Derby, who has made conſiderable plantations of mixed trees on rough ſtony land in Yorkſhire, ſays, that the Larch, of all, is his favourite. It not only outgrows every other tree, and that in the moſt expoſed ſituations; but he has reaſon to think it a moſt valuable wood, and that it will be taken out, as it grows, without damaging thoſe near it, which it has been the means of training ſtraight.

Some that were planted in 1785, were above twenty feet high in 1793.

Planting from the ſeed-bed is moſt advantageous, from the cheapneſs both in raiſing and planting, as well as from their ſucceeding ſo much better than in any other way [a].

Mr. White, who has made ſuch noble plantations at Butſfield in Durham, ſays that the Larch is not only ſuperior in beauty and hardineſs to the Scotch Pine, but furniſhes more durable and valuable timber; and is likewiſe a more tender and friendly nurſe to more delicate trees, being furniſhed with a great number of ſmall pliant branches well garniſhed with leaves; and which from their flexible quality will yield to the adjacent trees, and are not ſubject to laſh and buffet them; they alſo more readily admit the rains than the Scotch Pine does, and are not liable to receive injury in ſnowy ſeaſons, when the branches of the latter are frequently mutilated, and trees ſometimes totally deſtroyed.

Probably planters may have been often miſled by a miſtaken idea of the ſuperior hardineſs and nurturing quality of the Scotch Pine; or from not being acquainted with any other more proper tree to ſubſtitute in its place, have adopted it: in reſpect to ſhelter, it muſt be allowed to contribute in the winter more than deciduous trees; but as far as relates to the propaga-

tion

tion of the plantations themſelves, internal ſhelter at this dreary ſeaſon, when the powers of vegetation are totally locked up, is of much leſs conſequence, than in the more genial months, when the trees are making their ſhoots, the internal warmth of a plantation muſt then greatly facilitate the operations of nature, and the Larch, being one of the moſt early trees we have in the ſpring, is at that time in full foliage; and it is the moſt promiſing tree to aid thoſe operations.

The Larch alſo will thrive where few other trees will live; and when we conſider the many excellencies of this invaluable and pleaſing tree, it muſt be looked upon as a great misfortune to this country, that its introduction was not of an earlier date. About fifty years ago, I am told, this alpine plant was treated as a tender exotic, and planted out, with the utmoſt care and diligence, in our hot-beds and hot-houſes[4].

In this Mr. White muſt have been miſinformed, for my memory will carry me back half a century, and I never ſaw or heard of the Larch being treated otherwiſe than as a hardy tree; Miller, Evelyn, &c. certainly hint at no ſuch thing; and we have accounts of Larches planted in Scotland near ſeventy years ſince.

Mr. Marſhall informs us, that a ſtriking proof of the ſuperiority of the Larch in waterworks occurred on the eſtate of Athol. A weir or river dam, which, while conſtructed with Oak, required to be renewed every four or five years, was formed with Larch, and in 1792 had ſtood nine or ten years, the timber then remaining in a ſound firm ſtate. In gate-poſts the Larch has been found very durable.

In 1792, the Duke of Athol had a thouſand Larch trees then growing on his eſtates of Dunkeld and Blair only, of not leſs than from two to four tons of timber each; and had at that time a million of Larches, of different ſizes, riſing rapidly on his eſtate: which alone, if properly trained, would ſupply the Britiſh navy with ſhip-timber, for a length of years. The Highlands of Scotland alone, will henceforward be able to furniſh the whole commerce of the iſland with timber for its ſhipping.

Mr. Marſhall adds with great judgment—We have lands in England, and nearer to our ſhip yards, which will probably pay a hundred fold in Larch, compared with any other crop they are capable of producing. The barren heaths which occupy no inconſiderable portion of the kingdom; but more particularly, the ſingularly infertile plats of heath, in the ſouthern counties of Surrey, Suſſex and Hampſhire: lands, which at preſent, lie in a manner uſeleſs to the community; yet on which the Larch riſes with luxuriance.

If theſe waſtes ſhould be planted progreſſively with the Larch, properly trained for ſhip-building, the ſeveral yards of Portſmouth, Deptford, Chatham, &c. could not experience a want of timber for ages to come.

Were other waſtes of a ſimilar nature, lying in different parts of the iſland, particularly the mountain brows of the Engliſh highlands, in Yorkſhire, Weſtmoreland, &c. and alſo the Corniſh and Devonſhire mountains, with the Welſh and Salopian hills, with other barren heights, at preſent merely blank ſurfaces, converted to the ſame valuable purpoſe, a ſupply of foreign timber might, in half a century, become unneceſſary; and this, with little or no abridgment of agricultural produce.

The Larch not only flouriſhes in bleak and barren ſites, but increaſes with a rapidity unknown to every other durable wood. In the grounds of Blair of Athol, a Larch at five feet high girted upwards of eight feet, and contained by eſtimation four tons of timber, which was not, at the time it was meaſured, in 1792, fifty-four years old. At Dunkeld, another little more than fifty years old, girted at the ſame height eight feet ſix inches; its height was near one hundred feet, and its contents were from four to five tons of timber.

On the ſubject of the Larch we may ſafely conclude with Mr. Marſhall: that though we ſhould be very cautious how we are carried away by novel ideas and upſtart practices, however ſpecious; yet in the multitude of evidence here ſtated in favour of this tree, there ſeems ſufficient ground for deciſion; and that no time ought to be loſt in recommending it to the attention of government, and men of property in every diſtrict of the iſland, where barren heathy lands are found[5].

PINUS INDICA. See *Croton*.

PIPA. See *Cratægus Bibas*.

PIPER. (Πεπερι of *Theophraſtus* and *Dioſcorides*. *Derived* απο του πεπτειν, *concoquere*. *But it is probably of Indian origin.*)

Lin. gen. n. 43. *Reich. n.* 47. *Schreb. n.* 59. *Gaertn. t.* 92. *Juſſ.* 405. Saururus. *Plum.* 12.

Claſſ. 2. 3. Diandria Trigynia.

Nat. order of *Piperitæ*. *Urticæ*. Juſſ.

GENERIC CHARACTER.

CAL. *Spathe* none perfect.

Spadix filiform, quite ſimple, covered with florets.

Perianth none.

COR. none.

STAM. *Filaments* none. *Anthers* two, oppoſite, at the root of the germ, roundiſh.

PIST. *Germ* larger, ovate. *Style* none. *Stigma* three-fold, liſtpid.

PER. *Berry* roundiſh, one-celled.

SEED ſingle, globular.

ESSENTIAL CHARACTER.

Cal. none. *Cor.* none. *Berry* one-ſeeded.

SPECIES.

[1. Piper nigrum. *Black Pepper.*

Lin. ſpec. 40. *Juſſ.* 74. *Reich.* 1. 75. *Willd.* 159. *fl. zeyl. n.* 26. *mat. med.* 41. *Woodv. med. bot.* 513. *t.* 187. *Lour. cochinch.* 30. *Mill. illuſtr. Plunck, ic.* 25. *Marſd. Sumatra*, 105.

P. rotundifolium nigrum. *Bauh. pin.* 411. *Pluk. phyt. t.* 437. *f.* 1. *Mor. hiſt.* 3. 602. *f.* 15. *t.* 1. *f.* 1. *Blackw. t.* 348. *Raii hiſt.* 1341.

P. nigrum. *Park. theat.* 1603. *Ger. emac.* 1538.

Molago codi. *Rheed. mal.* 7. 23. *t.* 12.

Leaves ovate commonly ſeven-nerved ſmooth, petioles quite ſimple.

2. Piper Betle. *Betel.*

Lin. ſpec. 40. *Reich.* 1. 75. *Willd.* 159. *fl. zeyl. n.* 27. *Lour. cochinch.* 31. *Burm. zeyl.* 193. *t.* 83. *f.* 2. *Mor. hiſt.* 3. 603.

Amolago. *Rheed. mal.* 7. 31. *t.* 16. *Raii app.* 631.

Leaves ovate ſharpiſh rugged underneath, nerves ſcarce raiſed underneath.

7. Piper diſcolor.

Lin. ſpec. ed. Willd. 160. *Swartz prodr.* 15. *obſer.* 52.

Leaves broad-ovate five-nerved very ſmooth, diſcoloured on the under part, ſpikes more lax, florets more remote.

8. Piper medium.

Lin. ſpec. ed. Willd. 160. *Jacqu. ic. rar. t.* 8. *collect.* 1. 141.

[4] Tranſact. Soc. Arts, vol. 5. for 1787.

[5] Planting, vol. 1. 178 to 181.

Leaves ovate acuminate oblique subcordate at the base five-nerved, spikes axillary nodding.]

9. Piper Amalago. *Rough-leaved Pepper.*
Lin. spec. 41. *Reich.* 1. 76. *Willd.* 160. *Swartz obs.* 19. *Sloan. jam.* 1. 134. *t.* 87. *f.* 1. *Brown. jam.* 121. *n.* 1. *Pluk. phyt. t.* 215. *f.* 2.
Saururus foliis lanceolato-ovatis quinquenerviis rugosis. *Lin. hort. cliff.* 40.
Leaves lanceolate-ovate five-nerved wrinkled.

10. Piper Siriboa.
Lin. spec. 41. *Reich.* 1. 76. *Willd.* 161. *fl. zeyl. n.* 29.
Siriboa. *Rumph. amb.* 5. 340. *t.* 117.
Betela quem Siri-boa vocant. *Bont. jav.* 91. *t.* 91. *Raii hist.* 1913.
Leave cordate commonly seven-nerved veined.

[11. Piper excelsum.
Lin. spec. ed. Willd. 161. *Forst. prodr. n.* 20.
Leaves orbicular-cordate commonly seven-nerved, pedunculs terminating solitary bifid, stem arboreous.

12. Piper longum. *Long Pepper.*
Lin. spec. 41. *Reich.* 1. 76. *Willd.* 161. *fl. zeyl. n.* 30. *mat. med.* 41. *Woodv. med. bot.* 516. *t.* 188. *Plenck, ic. t.* 26. *Blackw. t.* 356. *Rumph. amb.* 5. 335. *t.* 116. *f.* 2. *Pluk. phyt. t.* 104. *f.* 4. *Raii hist.* 1343. *Ger. emac.* 1539. *Park. theat.* 1604.
P. longum orientale. *Bauh. pin.* 412.
Cattu-tirpali. *Rheed. mal.* 7. 27. *t.* 14. *Raii hist.* 3. 640.
Leaves cordate petioled and sessile.

13. Piper methysticum. *Intoxicating Pepper or Ava.*
Lin. spec. ed. Willd. 161. *Forst. prodr. n.* 21. *act. ul.* 76. *n.* 50.
Sirum decumanum. *Rumph. amb.* 5. 45. *t.* 27?
Leaves cordate acuminate many-nerved: spikes axillary solitary very short peduncled spreading very much.

14. Piper latifolium. *Broad-leaved Pepper.*
Lin. spec. ed. Willd. 161. *suppl.* 91. *Forst. prodr. n.* 22.
Leaves orbicular-cordate nine-nerved, spikes axillary aggregate peduncled.

15. Piper decumanum. *Plantain-leaved Pepper.*
Lin. spec. 41. *Reich.* 76. *ed. Willd.* 162.
Piper marginatum. *Jacqu. collect.* 4. 128. *icon. rar.* 2. 215.
Saururus frutescens foliis plantagineis, fructu breviori. *Plum. amer.* 59. *t.* 76. *Raii hist.* 3. 642.
Leaves cordate nine-nerved netted.]

16. Piper reticulatum. *Netted-leaved Pepper.*
Lin. spec. 41. *Reich.* 1. 76. *Willd.* 162. *Swartz obs.* 19.
Saururus botryoides major arborescens, foliis plantagineis. *Plum. amer.* 57. *t.* 76. *Raii hist.* 3. 643. 17.
Jaborandi. *Pis. bras.* 216. *med. bras.* 97.
Leaves cordate seven-nerved netted.

17. Piper aduncum. *Hooked-spiked Pepper.*

S. arborescens fructu adunco. *Plum. amer.* 58. *t.* 77. *Raii hist.* 3. 643. 18.
Leaves oblong-ovate acuminate unequal at the base veined, spikes solitary axillary uncinate.

[18. Piper macrophyllum.
Lin. spec. ed. Willd. 163. *Swartz prodr.* 15. *descr.* 54. *Brown. jam.* 122. *n.* 4.
P. longum arboreum fol. latissimis. *Sloan. jam.* 1. 135. *t.* 33. *Raii hist.* 3. 644. 19.
Leaves elliptic-ovate acuminate smooth unequal at the base veined, petiules appendiculed, spikes axillary solitary.

19. Piper geniculatum. *Jointed Pepper.*
Lin. spec. ed. Willd. 163. *Swartz prodr.* 15. *descr.* 57.
Leaves oblong acuminate oblique many-nerved smooth, stem and branches jointed.

20. Piper verrucosum. *Warted Pepper.*
Lin. spec. ed. Willd. 163. *Swartz prodr.* 15. *descr.* 56.
P. tuberculatum. *Jacqu. ic. rar.* 2. *t.* 211? *collect. suppl.* 7?

P. arboreum. *Aubl. guian.* 1. 23.
P. longum arb. foliis latissimis. *Sloan. jam.* 1. 135. *t.* 88. *f.* 1.
Arborescent, leaves oblong acuminate obliquely many-nerved veined smooth coriaceous, stem and branches swarted.

21. Piper hispidum. *Hairy-leaved Pepper.*
Lin. spec. ed. Willd. 163. *Swartz prodr.* 15.
P. hirsutum. *Swartz descr.* 60.
Leaves ovate acuminate obliquely hirsute wrinkled, nerves alternate veined, spikes erect.

22. Piper nitidum. *Shining-leaved Pepper.*
Lin. spec. ed. Willd. 163. *Swartz prodr.* 15. *descr.* 58.
Leaves lanceolate-ovate oblique at the base smooth shining.]

23. Piper pellucidum. *Pellucid-leaved Pepper.*
Lin. spec. 42. *Reich.* 1. 77. *Willd.* 163. *bort. cliff.* 6. *t.* 4. *Jacqu. obs.* 1. 16. *Kniph. orig. cent.* 10. *n.* 70.
Saururus minor procumbens botryitis, folio crasso cordato. *Plum. amer.* 54. *t.* 72. *Raii hist.* 3. 642. 12.
Leaves cordate petioled, stem herbaceous.

[24. Piper alpinum.
Lin. spec. ed. Willd. 164. *Swartz prodr.* 15. *descr.* 62.
Herbaceous, stem erect nearly simple, leaves ovate-roundish acute veinless underneath, spikes axillary.

25. Piper hispidulum.
Lin. spec. ed. Will. 164. *Swartz prodr.* 15. *icon. t.* 4. *descr.* 63.
Herbaceous, almost upright, leaves roundish petioled very thin rough-haired above.

26. Piper tenellum.
Lin. spec. ed. Willd. 164. *Swartz prodr.* 16. *descr.* 65.
Herbaceous simple decumbent, leaves distich ovate veinless ciliate at the edge, spike ascending.

27. Piper acuminatum.
Lin. spec. 42. *Reich.* 1. 77. *Willd.* 164. *Swartz obs.* 20. *Sloan. jam.* 1. 136.
Saururus alius humilis, folio carnoso & acuminato. *Plum. amer.* 54. *t.* 71. *Raii hist.* 3. 643.
Herbaceous, leaves lanceolate-ovate nerved fleshy, stem almost upright.

28. Piper blanium.
Lin. spec. ed. Will. 164. *Jacqu. collect.* 3. 211. *icon. rar.* 2. 218.
Leaves in threes lanceolate acuminate three-nerved ciliate dotted underneath.

29. Piper amplexicaule.
Lin. spec. ed. Willd. 165. *Swartz prodr.* 16. *descr.* 67.
Subherbaceous, leaves lanceolate-ovate embracing nerved fleshy, stem erect simple.

30. Piper pallidum.
Lin. spec. ed. Willd. 165. *Forst. prodr. n.* 24.
Leaves alternate obovate commonly three-nerved, spikes solitary subterminating.]

31. Piper obtusifolium. *Blunt-leaved Pepper.*
Lin. spec. 42. *Reich.* 1. 77. *Willd.* 165. *Trew. ehret.* 54. *t.* 96.
Saururus humilis folio carnoso subrotundo. *Plum. amer.* 53. *t.* 70. *Raii hist.* 3. 643. 14.
Leaves obovate nerveless.

[32. Piper retusum.
Lin. suppl. 91. *spec. ed. Willd.* 165.
Leaves obovate retuse.

33. Piper glabellum.
Lin. spec. ed. Willd. 165. *Swartz prodr.* 16. *descr.* 68.
Herbaceous, leaves ovate acuminate, stem declined rooting very much branched.

34. Piper serpens.
Lin. spec. ed. Willd. 165. *Swartz prodr.* 16. *descr.* 69.
Herbaceous, leaves roundish-acute flat discoloured, stem creeping.

35. Piper cordifolium.
Lin. spec. ed. Willd. 165. *Swartz prodr.* 16. *descr.* 71.

Herbaceous, leaves obcordate petioled plano-convex fleshy, stem creeping.

36. Piper nummularifolium.
Lin. spec. ed. Willd. 166. *Swartz prodr.* 16. *descr.* 72.
Herbaceous, leaves orbicular concavo-convex, stem filiform creeping rooting.

37. Piper rotundifolium.
Lin. spec. 42. *syst.* 74. *Reich.* 1. 77. *Willd.* 166. *Swartz obs.* 20. *Jacqu. obs.* 1. 17. *Sloan. jam.* 1. 137.
Saururus repens, folio orbiculari nummulariæ facie. *Plum. amer.* 52. *t.* 69. *Raii hist.* 3. 641. 7.
S. minimus rep. fol. orbic. tumentibus. *Brown. jam.* 204. *n.* 6.
Herbaceous, leaves roundish flat fleshy, stem filiform creeping.

38. Piper maculosum.
Lin. spec. 42. *Reich.* 1. 77. *Willd.* 166.
Saururus hederaceus caulibus maculosis major. *Plum. amer.* 50. *t.* 66. *Raii hist.* 3. 642. 8.
Leaves peltate ovate.]

39. Piper peltatum.
Lin. spec. 42. *Reich.* 1. 77. *Willd.* 166.
Saururus arborescens, foliis amplis rotundis & umbilicatis. *Plum. amer.* 56. *t.* 74. *Raii hist.* 3. 643. 16.
S. fol. ampl. orbiculato-cordatis peltatis, petiolis vaginantibus. *Brown. jam.* 203. *n.* 2.
Leaves peltate orbicular-cordate blunt repand, spikes umbelled.

[40. Piper subpeltatum.
Lin. spec. ed. Willd. 166.
Lonuba. *Rumph. amb.* 6. 133. *t.* 59. *f.* 1.
Leaves subpeltate orbicular-cordate acuminate, spikes umbelled.

41. Piper distachyon.
Lin. spec. 42. *Reich.* 1. 78. *Willd.* 167. *Swartz obs.* 21.
Saururus hederaceus caulibus maculosis minor. *Plum. amer.* 51. *t.* 67. *Raii hist.* 3. 642. 9.
Leaves ovate acuminate, spikes conjugate, stem rooting.

42. Piper umbellatum. *Umbelled Pepper* or *Santa Maria leaf.*
Lin. spec. 43. *Reich.* 1. 78. *Willd.* 167. *Swartz obs.* 21. *Jacqu. collect.* 2. 335.
Saururus arborescens, foliis amplis cordatis non umbilicatis. *Plum. amer.* 53. *t.* 73. *Raii hist.* 3. 643. 13.
S. fol. ampl. orbiculato-cordatis, sinu aperto, petiolis vaginantibus. *Brown. jam.* 203. 1.
Leaves orbicular-cordate acuminate veined, spikes umbelled, stem erect grooved pubescent.

43. Piper trifolium. *Three-leaved Pepper.*
Lin. spec. 43. *Reich.* 1. 78. *Willd.* 167.
Saururus hederaceus triphyllus, folio rotundo. *Plum. amer.* 52. *t.* 68. *Raii hist.* 3. 641. 6.
Leaves in threes roundish.

44. Piper peltæfolium.
Lin. spec. ed. Willd. 167. *Jacqu. collect.* 4. 126. *icon. rar.* 2. 219.
Leaves in whorls of three or four elliptic three-nerved smooth, spike terminating solitary, stem spotted.

45. Piper polystachyon. *Many-spiked Pepper.*
Lin. spec. ed. Willd. 167. *Ait. kew.* 1. 49.
P. obtusifolium. *Jacqu. collect.* 1. 141. *icon. rar.* 1. *t.* 9.
Leaves in whorls rhomb-ovate quite entire, petioled three-nerved pubescent.

46. Piper quadrifolium.
Lin. spec. 43. *Reich.* 1. 78. *Willd.* 168. *Swartz obs.* 22. *Plum. amer. t.* 242. *f.* 3.
Leaves in fours wedge-form obovate emarginate subsessile, stem erect.

47. Piper verticillatum. *Whorl-leaved Pepper.*
Lin. spec. 43. *Reich.* 1. 78. *Willd.* 168. *amoen.* 5. 391.
Saururus erectus minor, foliis orbiculatis verticillatis tumentibus, spicis terminalibus. *Brown. jam.* 204. *n.* 8.
Leaves in whorls four together elliptic blunt three-nerved.

48. Piper stellatum. *Starry-leaved Pepper.*
Lin. spec. ed. Willd. 168. *Swartz prodr.* 16. *descr.* 74. *Jacqu. collect.* 2. 212. *icon. rar.*

Leaves in whorls three, four or five together oblong acuminate three-nerved.

49. Piper reflexum. *Reflex-leaved Pepper.*
Lin. spec. ed. Willd. 168. *suppl.* 91. *Swartz obs.* 23.
P. tetraphyllum. *Forst. prodr. n.* 25.
Leaves in fours rhombed fleshy reflex and patulous, stem creeping.

50. Piper pulchellum. *Small-leaved Pepper.*
Lin. spec. ed. Willd. 169. *Ait. kew.* 1. 50.
Leaves in fours subsessile oblong nerveless quite entire, stem round, spikes terminating.

51. Piper filiforme.
Lin. spec. ed. Willd. 169. *Swartz prodr.* 16. *icon. t.* 6. *descr.* 73.
Herbaceous, leaves linear blunt, the uppermost in whorls, stem filiform creeping.

Species from Vahl's Eclogæ.

52. Piper ovatum.
Vahl ecl. 1. 3.
Leaves ovate veined many-nerved equal at the base, berries pedicelled distant, branches even.

53. Piper caudatum.
Vahl ecl. 1. 3.
P. caudatum ſ. Nhandu. *Marigr. bras.* 75. *Raii hist.* 1343.
Nhandi. *Pis. bras.* 96. *hist.* 97.
Leaves cordate-nine-nerved veined smooth attenuated with a deep sinus at the base.

54. Piper rugosum.
Vahl ecl. 1. 4.
Leaves ovate-oblong veined smooth nearly equal at the base netted underneath, branches even, petioles simple.

55. Piper æquale.
Vahl ecl. 1. 4.
Leaves elliptic-lanceolate veined attenuated equal at the base smooth, branches even knee-jointed.

56. Piper præmorium.
Vahl ecl. 1. 4. *Rotboell surin.* 16.
Leaves lanceolate-elliptic attenuated smooth, shorter on one side at the base, spikes recurved at top.

57. Piper obovatum.
Vahl ecl. 1. 5.
Leaves in threes petioled obovate emarginate smooth, stem creeping.

58. Piper microstachyum.
Vahl ecl. 2. 3.
Leaves oblong acuminate equal at the base veined underneath, spikes very short mucronate.

59. Piper grande.
Vahl ecl. 2. 3.
Leaves ovate-oblong acuminate many-nerved, equal at the base and petioles.

60. Piper scabrum.
Swartz descr. 59.
Leaves broad-ovate acuminate oblique wrinkled rugged, spikes erect.

DESCRIPTIONS, &c.

Moſt of the Peppers are perennial. Stems herbaceous or fruteſcent, often ſcandent and dichotomous; the branches as it were jointed. Leaves on an embracing petiole, moſt alternate, others oppoſite, with one of them frequently caducous or abortive. Spikes axillary when the leaves are oppoſite, oppoſite when the leaves are alternate, commonly ſolitary and naked, ſeldom ſeveral in bundles, and accompanied with bractes, as in *Piper peltatum* and *umbellatum**.

Forſter remarks, that in many ſpecies the number of ſtamens is indeterminate: and that the number and forms of the ſtigmas differ in moſt. Loureiro alſo obſerved the difference of the ſtigmas to be variable, but not to recede much from the number three. In thoſe ſorts which have a ſeparate fruit he remarked two ſtamens; but in thoſe which have a concrete fruit, lengthened out into a ſpike like a mouſe's tail, ſuch as are enumerated by Linnæus from Plumier, and by Aublet, he could not number the ſtamens even with a microſcope, and he doubts whether any one ever numbered them. Both he and Juſſieu heſitate to admit

* Juſſieu. gen.

theſe as ſpecies of Piper. The numerous ſpecies of this genus are natives of the Eaſt and Weſt Indies, a few of the iſlands in the South Seas, two or three of the Cape of Good Hope, none of Europe.

1. Stem ſhrubby, very long, round, ſmooth, jointed, ſwelling towards each joint, ſlender, branched, ſcandent or trailing, rooting at the joints. Leaves acuminate, quite entire, equal at the baſe, flattiſh, bent back a little at the top and edges, alternate, of a dark green colour, at the joints of the branches upon ſtrong ſheath-like footſtalks. Flowers ſeſſile, lateral and terminating, in ſimple, longiſh ſpikes, oppoſite to the leaves. Calyx always four-leaved, imbricate: leaflets thick, concave, very blunt, unequal. Filaments two, awl-ſhaped, flat, equal to the calyx, and hid by its leaflets. Anthers ovate, prominent above the calyx. Germ globular, ſuperior. Stigmas ſeſſile, commonly four, ſometimes but ſeldom three or five, oblong, reflex, ſharp. Berry globular, of a red brown colour[f].

Black Pepper grows ſpontaneouſly in the Eaſt Indies and Cochinchina. It is cultivated with ſuch ſucceſs in Malacca, Java, and eſpecially in Sumatra, that it is thence exported to every part of the world, where a regular commerce has been eſtabliſhed. It is exported alſo from Cochinchina.

White Pepper was formerly thought to be a different ſpecies from the Black; but it is nothing more than the ripe berries deprived of their ſkin, by ſteeping them about a fortnight in water; after which they are dried in the ſun. The berries falling to the ground when over-ripe loſe their outer coat, and are ſold as an inferior ſort of White Pepper.

Black Pepper is the hotteſt and ſtrongeſt, and moſt commonly uſed for medicinal as well as culinary purpoſes. It differs from moſt of the other ſpices in this, that its pungency reſides not in the volatile parts or eſſential oil, but in a ſubſtance of a more fixed kind, which does not riſe in the heat of boiling water. This fixed ſubſtance is probably the reſinous part: the aromatic odorous matter ſeems to depend upon the eſſential oil. The diſtilled oil ſmells ſtrongly of the Pepper, but has very little acrimony; the remaining decoction inſpiſſated yields an extract of conſiderable pungency. A tincture made in rectified ſpirit is extremely hot and fiery.

Some have ſuppoſed Pepper to be leſs heating to the ſyſtem than other aromatics. It is generally uſed as an aromatic and ſtimulant, and has been ſucceſsfully employed in ſome caſes of vertigo, in paralytic and arthritic diſorders. Given in large doſes, it has been found a remedy for intermittents; but it is ſaid, in ſome inſtances to have produced fatal conſequences, in this diſorder[g].

Loureiro has a ſpecies, which he calls *Piper ſylveſtre*, growing wild in the woods of Cochinchina, but not applied to any purpoſe. He ſuſpects it to be the ſame with Piper caninum of Rumphius (*l. 7. c. 26. t. 28. f. 2.*)

He has alſo a ſecond ſpecies, with pinnate leaves, conſiſting of three pairs of leaflets; which he therefore names *Piper pinnatum*. The ſtem is erect and prickly. He propoſes this ſpecies with doubt, becauſe he had no opportunity of examining the plant whilſt it was in flower. In China, where it grows naturally, both leaves and fruit are applied to culinary uſes: it is alſo uſed medicinally.

2. Stems ſmooth and even, ſtriated, angular. Leaves acuminate, a little oblique at the baſe; the three middle of the ſeven nerves run to the end of the leaf, the outmoſt are very ſhort. Peduncle longer than the petiole, and oppoſite to it. Spike cylindrical, frequently together with the peduncle pendulous. Petiole channelled at the baſe[h].

Stem ſhrubby, manifold, very long, trailing and rooting at the joints. Leaves unequal at the baſe, curved in, veined, ſhining, alternate, aromatic, hotriſh; the petioles ſeldom two-toothed. Spike ſlender, long, ſolid: peduncle ſolitary, ſimple, oppoſite to the leaf. Stigmas four or five, linear, ſeſſile, ſpreading out. Berries flatted-angular, united, half-concealed, inſeparable[i].

Native of the Eaſt Indies.

It is the leaf of this ſpecies of Pepper plant which is called Betle or Betel, and ſerves to incloſe a few ſlices or bits of the Areca, thence erroneouſly called the Betel-nut, theſe together with a little Chunam or ſhell-lime are what the ſouthern Aſiatics ſo univerſally chew to ſweeten the breath and ſtrengthen the ſtomach: the lower people there uſe it as ours do tobacco in Europe to keep off the calls of hunger. The conſumption of Betel is ſo great in the Eaſt as to occaſion a conſiderable branch of commerce: it is there deemed the height of unpoliteneſs to ſpeak to a ſuperior without ſome of it in the mouth. The women of Canara on the Malabar coaſt ſtain their teeth black with Antimony, and thus preſerve them good to old age; whereas the contrary is the caſe with the men, who ruin theirs by the Betel, and the Chunam or lime, which they take along with it. Ulloa aſſerts that the Coca (or Koka) of Peru is the ſame with the Betel[k].

3. This is a very ſmooth ſhrub, with a jointed flexuoſe ſtem. Leaves moſtly oblong, ſeldom ovate or lanceolate, not tender as in moſt ſpecies of this genus, quite entire, petioled, veined; the veins ſimple, alternate; the margin of the leaf does not run down ſo far on one ſide as on the other. Spikes ſolitary, peduncled, ſhort, on which are thoſe pedicelled berries known in the ſhops and the kitchen by the name of *Cubebs*[l].

The berry is fleſhy, globular, obſcurely umbilicate at top, red or when old of a ſmoky colour, ſmooth, one celled: pulp moderately thick, finally drying up into a coriaceous pellicle. Seed ſingle, ſubglobular, umbilicate at top with a ſmall excavation, ferruginous-brown, a little wrinkled: cover ſingle, membranaceous, faſtened cloſely to the albumen; which is of the ſame ſhape with the ſeed, ſomewhat granular, friable, pale yellow, aromatic, acrid, having a very ſmall excavation near the top: embryo very minute, inverted, milky, placed in the proper cavity of the albumen, which is cloſed only by the integument, as in the Palms: cotyledons two very minute, papillary, diverging: radicle diſcoid with a middle point, ſuperior, faſtened to the cover of the ſeed[m].

Native of the iſland of Java, in woods. Bergius alſo communicated it from Guinea.

4. The whole of this is ſmooth. Stem perennial, thicker than a quill, branched, a foot high, at firſt upright, but afterwards becoming decumbent from the weight of leaves and branches, and throwing out roots from the joints; by which perhaps in its native ſoil it faſtens itſelf to trees. Leaves alternate, quite entire, ſometimes emarginate, thick, ſomewhat fleſhy, obſcurely veined, nerveleſs, very dark green with the edges ſometimes of a dirty blood colour, on very ſhort petioles, channelled at the baſe, with the nerve at the back projecting; they are about four inches in length. Spike round, upright, green, four inches long, about half the thickneſs of a quill; on a peduncle an inch in length, purpliſh, jointed at the baſe, and often rolled back at the top. Anthers oblong, grooved, brown, ſeſſile. Germ green, ending in an acute erect little bracte. Stigmas three, oblong, brown, ſomewhat hiſpid, ſeſſile on the outſide at the baſe of the bracte.—Native of the Weſt Indies[n].

5. This is diſtinguiſhed from the other larger ſpecies of the genus, which it reſembles very much, by having the veins of the leaves villoſe on the lower ſurface.

Found at the Cape of Good Hope by Thunberg[o].

6. Stems round, ſtriated, twining. Leaves thin, green above, ſubcinereous-rugged underneath: they have five nerves, and no more, not at all raiſed above: the petioles are round[p].—Native both of the Eaſt and Weſt Indies.

7. This is a ſhrub, a fathom in height, with alternate, erect, ſubdivided, jointed, round, ſmooth branches.

[f] Loureiro. [g] Woodville. [h] Linn. zeyl. [i] Linn. ſuppl. [k] M. S information from Rev. G. Aſhby. [l] Gærtner. [m] Jacquin. [n] Linn. ſuppl. [o] Linn. zeyl. [p] Linn. zeyl.

Leaves alternate, broad-cordate or ovate, with a blunt point, entire, thickiſh, veined, whitiſh or very pale green underneath, ſhining; two of the five nerves are marginal: joints ſwelling: petioles channelled, ſhort. Spikes pedicelled, ſolitary, oppoſite to the petiole, ſhorter than the leaves, ſlender. Peduncles longer than the petioles, round, ſmooth. There is no calyx, but an oblong ſcale, within which are two very ſhort evaneſcent filaments, and two obovate, whitiſh anthers. Germ oblong, within the ſcale: ſtyle ſhort, thickiſh: ſtigmas three, ſmall, acute. Berry minute, oblongiſh. It is diſtinct from *P. Amalago* in its wide very ſmooth leaves, looſer ſpikes, and more remote flowers.

Native of high mountains in Jamaica; flowering in autumn.

It varies with leaves attenuated at the baſe, and blunt, ovate, oblique [1].

8. This ſpecies is ſufficiently different from *P. decumanum* and *reticulatum*, on account of the five-nerved leaves, and the baſe of the leaves being very ſhortly and not always cordate. It ſeems more allied to the next ſucceeding ſpecies; but differs from that in having the leaves ſubcordate at the baſe, oblique and not ſo roundly ovate [2].

It has ſeveral trunks, eight feet high, two inches in diameter at the baſe, upright, jointed, knobbed, aſh-coloured. Branches numerous, round, ſwelling at the joints. Leaves alternate, three or five-nerved, quite entire, ſmooth, netted underneath with tranſverſe veins, petioled, having a bitteriſh aromatic taſte, and the ſame ſmell when bruiſed. Spikes ſolitary, peduncled, ſlender, oppoſite to a leaf, upright, three or four inches long. Germ angular. Stigma triple, quadruple or quintuple. Anthers from two to five, ſurrounding the germ in no fixed ſituation. It ſeems to be a middle ſpecies between *decumanum* and *reticulatum*, and derives its trivial name from that circumſtance.—The native country is unknown [3].

9. This is a ſhrub from three to ten feet in height. Stem even: branches dichotomous, jointed, ſubdivided, round, browniſh green. Leaves alternate, acuminate, not obſique, nerved and veined, very thin, bright green, ſmooth, paler underneath. Petioles round, ſmooth. Joints ſwelling. Spikes peduncled, oppoſite to the leaves, filiform, looſe, many-flowered. Flowers cluſtered. No calyx, corolla, or filament. Anthers from two to four, at the baſe of the germ, cordate-ovate, ſeſſile, two-celled. Germ ovate: ſtyle none: ſtigmas three, oblong, ſeſſile. Berry ſeſſile, containing a ſingle ſeed, double the ſize of Hemp-ſeed, black when ripe, of a taſte ſlightly pungent [4].

It has ſeveral crooked ſtems, which riſe to the height of twelve or fourteen feet, are jointed, hollow and pithy; they divide into many ſmall branches. Leaves three inches and a half long, and one inch and a half broad, and rough. Spikes at the end of the branches, ſlender, three inches long, having many ſmall ſeſſile flowers, ſucceeded by ſmall berries.

[Browne calls it ſmall-grained Black Pepper, and ſays that it grows very common in moſt of the hilly parts of Jamaica, looking very buſhy, and ſpreading on account of its ſlender flexile branches; it begins to divide very near the root, and riſes in tufts, frequently to the height of ſix or eight feet or more. The berries differ from the Black Pepper of the Eaſt Indies only in ſize, being ſeldom bigger than a large Muſtard ſeed; but the taſte and flavour is in every reſpect the ſame: the leaves and growth of the ſhrub very nearly reſemble that deſcribed in the Hortus Malabaricus, but the plant is neither ſo luxuriant nor ſucculent.

Browne uſed it for many months, and could not perceive any ſenſible difference between it and that of the Eaſt either in cookery or ſeaſoning.

It ſhould be picked when full grown, but before it ripens; for, like the Pimento and other ſpicy grains, it grows ſoft and ſucculent by maturity, and demits the pungent flavour: it may then be dried in the ſun like the Pimento, and left adhering to the ſpikes, which ſeem to have the ſame flavour and pungency with the grain itſelf, and are as eaſily ground in the mill.

The leaves and tender ſhoots are uſed in diſcutient baths and fomentations, and ſometimes are pounded and applied to foul ulcers: the root is warm, and may be ſucceſsfully adminiſtered as a reſolutive, ſudorific or diaphoretic; but it anſwers beſt in infuſions or light decoctions, which may be varied in ſtrength as occaſion requires. There is no deobſtruent of this nature that anſwers better in dropſies, or lighter obſtructions from a lentor or inertion.

Native not only of Jamaica but of Hiſpaniola, Barbadoes, and probably other parts of the Weſt Indies. Cultivated by Mr. Miller in 1759 [5].

10. Stem even, not very hard. Leaves alternate, a ſpan long, petioled, acute; nerves alternate (ſeven or) nine; the three inner ones running to the tip; the outmoſt very ſhort, the reſt gradually longer; all with anaſtomozing veins. Peduncle oppoſite to the petiole. Spike ſlender, narrow. Petioles round, not ſheathing [6].]

Stems hollow, ſhrubby, about four feet high, dividing into many ſmall branches. Leaves about five inches long, and four broad near their baſe, ending in long acute points; they have ſeven veins at the baſe, but the two outer ſoon diverge to the borders of the leaves, and unite with them, the other five are extended almoſt to the length of the leaves, diverging from the midrib towards the ſides, and unite near the top. The ſpikes come out from the ſide of the branches; they are ſlender, and about four inches long, bending in the middle like a bow, and are cloſely ſet with ſmall herbaceous flowers, which are ſucceeded by ſmall berries, incloſing a ſingle ſeed. Mr. Robert Millar ſent it from Panama.

[Native of the Eaſt Indies, and New Caledonia. Cultivated by Mr. Miller in 1759.

11. Native of New Zealand [7].

12. Stems ſhrubby, round, ſmooth, branched, ſlender, climbing, but not to any conſiderable height. Leaves differing much in ſize and form; but commonly heart-ſhaped, pointed, entire, ſmooth, nerved, deep green, alternate. Flowers ſmall, in ſhort denſe terminating ſpikes, which are nearly cylindrical [8].

Linnæus remarks, that this ſpecies has the appearance of *Ariſtolochia Piſtolochia*; that the petioles of the leaves are quite ſimple; that the upper leaves are very oblong, often ſeſſile, blunter and narrower than the lower ones, and ſome embracing; and that the branches are dichotomous [9].

Native of the Eaſt Indies, eſpecially Java, Malabar and Bengal.

The berries are very ſmall, and lodged in a pulpy matter: like thoſe of Black Pepper they are firſt green, and become red when ripe: they are hotteſt to the taſte in the immature ſtate, and are therefore gathered whilſt green, and dried in the ſun; when they change to a blackiſh or dark gray colour.

Dr. Cullen obſerves, that long Pepper has the ſame qualities with the Black, but in a weaker degree. Bergius alſo judges Black Pepper to be hotter than this. The contrary however is aſſerted by Lewis and Murray [10].

13. Stem dichotomous, ſpotted, attaining the height of a fathom. Leaves oblong-cordate, not roundiſh-cordate, as in the next ſpecies. Spikes ſtraight, ſhort, ſolitary, and not aggregate, long, nodding, as in that.

The root of this plant bruiſed, or more frequently chewed in the mouth, and mixed with the ſaliva, yields that naſeous, hot, intoxicating juice, which is ſo acceptable to the natives of the South Sea iſlands, and is ſpoken of with ſo much deteſtation by our voyagers. They pour the liquor of the Cocoa-nut or pure water into it; but the leſs it is diluted, the more this acrid, poiſonous, naſeous beverage is eſteemed among the chiefs, to whom the uſe of it is moſtly confined, becauſe they become intoxicated, and then fall aſleep the ſooner. The conſequences of uſing

[1] Swartz deſcr. [2] Willdenow. [3] Jacquin. [4] Swartz obſ. [5] Hort. kew. [6] Linn. zeyl. [7] Forſter. [8] Woodville. [9] Linn. zeyl. [10] Woodville.

this deteſtable liquor too freely are deſcribed as dreadful. The eyes and the whole body are enflamed, the ſkin becomes parched up, exfoliates in ſcales, and throws out leprous ulcers, till at length decay and conſumption enſue: and yet even thoſe who are accuſtomed to it, cannot take the naufeous draught without making wry faces, and their limbs quaking with horror. In Otaheite it is called *Ava*, in the Friendly and Sandwich iſlands, with a ſtrong aſpiration *Kava*. It is cultivated in all the iſlands of the South Sea, except the New Hebrides and New Caledonia[a].

14. Leaves large, roundiſh, deeply cordate, acute, quite entire, very ſmooth, tender, with from eleven to thirteen nerves. Petioles dilated at the baſe and embracing. Spikes five or more[c].

Native of the Society and Friendly iſlands, the New Hebrides, in ſhort of almoſt all the iſlands of the South Sea, within the Tropics. It has none of that intoxicating quality which P. methyſticum poſſeſſes, nor is it ever put to any uſe by the natives[a].

15. Stems ſeveral, ſhrubby, upright, branched, ſmooth, a little knobbed, the height of a man and more, an inch and upwards in thickneſs at the baſe, when old brown, when young green. Leaves alternate, cordate, acuminate, quite entire, having nine or eleven nerves, ſomewhat villoſe on the veins when examined by a glaſs, in other parts ſmooth, the longer ones a foot in length including the petioles; theſe are winged with a pale channelled membrane, in the longer leaves four inches in length. Spikes oppoſite to a leaf, ſolitary, round, three inches long, upright, ſlender, pale, on a green peduncle an inch in length. Anthers twin, grooved, firſt pale yellow, then brown. Germ roundiſh, with a ciliate ſtigma occupying its upper margin. When adult it throws out roots from the joints. It has an aromatic ſmell, but an unpleaſant taſte[f].

Linnæus remarks, that it is ſo nearly allied to *reticulatum*, as almoſt to ſeem a variety; and that it is a native of both Indies. Jacquin aſcribes it to the Caraccas[g].

16. This is a ſhrub, a fathom in height and more. Stem round, upright, ſmooth. Branches ſomewhat jointed. Leaves alternate, large, conſiate-rounded, acuminate, nine-nerved, ſmooth. Petioles ſmooth, ſtriated, ſheathing. Spikes long, pedunculed, oppoſite to the leaves, round, upright. Peduncles ſhorter than the petioles. Stamens and piſtils inſerted ſpirally into the ſpike. Filaments ſcarcely any. Anthers two, ſubſeſſile, opening tranſverſely at top. Germs under the anthers. Styles three, thickiſh. Stigmas blunt[h].]

Stem about five feet high, ſending out ſeveral ſide branches which have protuberant joints. Leaves ſix inches long and five broad near their baſe: they have five veins ſpringing from the foot-ſtalk, the middle one going in a direct line to the point; the two ſide veins diverge towards the edges of the leaves in the middle, but approach again at the top; the ſurface of the leaves is full of ſmall veins, which form a ſort of net-work. The ſpikes come out from the ſide of the branches oppoſite to the leaves; they are ſlender, and about five inches long, a little bending in the middle, and are cloſely ſet with very ſmall herbaceous flowers.

Native of Jamaica, [Martinico, Hiſpaniola, Braſil. Cultivated by Mr. Miller in 1759.

17. Stems ſeveral, ſhrubby, round, knobbed at the joints, ſmooth, an inch and more in thickneſs, branched, aſh-coloured, upright, eight feet high. Branchlets green, the thickneſs of a quill, ſpreading very much. Leaves alternate, on ſhort petioles, in a double row, a little ſhorter at the inner baſe, deep green above, rugged backwards, rough-haired when examined by a glaſs; underneath pale green, villoſe but not rugged; quite entire, netted with numerous veins, many-nerved if the principal veins be conſidered as nerves; they are about half a foot in length, and have little taſte or ſmell. Stipulæ lanceolate, acute, converging, ſmooth, ſtriated, caducous. Peduncles alternate, oppoſite to a leaf, ſolitary, erect, round, ſomewhat villoſe, half an inch long. Spikes ſolitary, ſlender, yelloviſh, two or three inches in length, towards the origin of the branchlet bowed, ſo cloſely covered with minute fructifications, that it is ſcarcely poſſible to detect their ſtructure even with a microſcope[i].]

Stalks many, hollow, about five feet high, with joints pretty cloſe and protuberant; they divide into ſmaller branches. Leaves ſeven inches long, and three broad in the middle, rough; the veins come out alternately from the midrib, diverging to the ſides, and join the borders of the leaf at the top. The ſpikes of flowers come out from the ſide of the branches, oppoſite to the leaves; they are ſlender, five inches long and incurved, cloſely ſet with flowers their whole length. It is called Spaniſh Elder in Jamaica, of which iſland it is a native, [as alſo of Barbadoes, Dominico, and the Caraccas. Cultivated by Mr. Miller in 1759.

18. This is a large ſhrub, two fathoms in height. Stem round, ſtriated. Branches almoſt erect, ſmooth. Leaves alternate, large, bluntly acuminate, oblique at the baſe, having ten or twelve nerves tranſverſely oblique, veined, quite entire. Petioles ſhort, broadiſh, channelled, membranaceous with a leafy margin, appendicled at the baſe of the leaf. Spikes pedicelled, long, erect, oppoſite to the leaves. Flowers very cloſe, not diſtinct. Filaments four to ſix, very ſhort, or elſe the anthers ſeſſile, twin, round the germ. Styles none. Stigmas three ſeſſile. The ſtem and branches are leſs brittle than in the other ſpecies.

Native of the Weſt Indies, on rocky mountains: Jamaica, Martinico, &c.

19. This ſhrub is alſo two fathoms high and more. Stem ſubdivided towards the top, round, ſmooth. Branches and branchlets long, rod-like, round, ſmooth, very brittle. Joints ſwelling. Leaves alternate, half a foot long and more, attenuated but blunt at the top, rounded and unequal at the baſe, entire. Petioles ſhort, channelled, ſmooth. Spikes ſolitary, oppoſite to the leaves, long, pedicelled. Flowers ſpiral, as in *P. verrucoſum*. Stem, though often thick, yet ſo weak as to require ſupport from other ſhrubs. It is diſtinguiſhed from *P. macrophyllum*, which it reſembles very much, by its jointed habit, brittleneſs, &c.—from *P. verrucoſum*, by its joints, thinner leaves, and even ſtem and branches.—Native of Jamaica, in ſtony woods[k].

20. This is a tree the trunk of which is from fifteen to twenty feet in height, upright, with the bark much warted. Branches ſimple, terminating, leafy, round, with white warts. Leaves ovate, acuminate, blunt, alternate, veined, the margin rolled in; the largeſt from one foot to two feet in length. Petioles ſhort, channelled, with the margins at the baſe of the leaf membranaceous, warted. Spikes pedicelled, half a foot long, oppoſite to the leaf, upright. Flowers in a ſpiral, the males and females in a manner diſtinct. Germs between the upper and lower circuit of ſtamens. Anthers two ovate, placed obliquely. Stigmas three, ſeſſile. It is known by its habit, its warted ſtem and branches, and its large coriaceous leaves.

Native of Jamaica, on calcareous rocks in the interior of the iſland[l]: Guiana, &c.

21. This is a ſhrub: the ſtem is a fathom in height, upright, round, hirſute, hiſpid. Branches patulous, flexuoſe, jointed, round, hirſute: joints hirſute and hiſpid. Leaves alternate, many-nerved, hirſute, hiſpid; nerves alternate, raiſed on the back of the leaf: petioles ſhort, round, not channelled. Spikes pedicelled, oppoſite to the leaves, ſolitary, two inches long, cylindrical, thick, brown. Peduncles thick, round, hiſpid, ſhorter than the petioles. Flowers aggregate. Calyx none: but ſmall, roundiſh, ciliate ſcales; by the ſides of which are two very ſhort filaments. Anthers extremely minute, roundiſh, twin. Germ ovate. Styles none. Stigmas three, reflex, very ſmall. Berry ſeſſile, roundiſh, very ſmall. It differs from *P. ſcabrum* by its remarkable hirſute and hiſpid habit. To avoid being confounded with *P. hiſpidulum*, Swartz changed

[a] Forſter. Cook's laſt voy. 1. 318.
[c] Linn. ſuppl. [f] Forſter. [g] Jacquin. [h] Swartz obſ. [i] Collect. [k] Jacquin. [l] Swartz deſcr. [m] Idem.

the name from *hiſpidum*, which he firſt gave it, to *hirſutum*.

Native of Jamaica, on the cooler mountains; flowering in autumn.

22. This alſo is a ſhrub, the height of a man, very much branched, with a ſmooth round trunk. Branches and branchlets always jointed at the inſertion of the leaves, brittle. Leaves alternate, oblique at the baſe on the outer ſide, veined, dark green, from two to three inches long. Petioles very ſhort, round. Spikes peduncled, ſhortiſh, round, upright, very even, whitiſh. Peduncles oppoſite to the leaves, ſhort. Flowers very much crowded.

Native of Jamaica, in mountain woods; flowering in ſpring *.]

23. This is annual. Stalks ſucculent, ſeven or eight inches high. Leaves an inch and half long, and three quarters of an inch broad. The ſpikes of flowers come out at the end of the ſtalks; they are ſlender, about an inch long and ſtraight; the flowers are very ſmall, and ſeſſile, appear in july, and are ſucceeded by very ſmall berries, each containing a ſmall ſeed like duſt.

[Native of South America and the iſlands, on the gravelly banks of torrents and rivers, being fond of moiſture. In Martinico they eat the leaves as ſalad, with lettuce or alone, with oil and vinegar, and call it Creſſon; but it has too powerful a ſmell and taſte to be agreeable to Europeans *. It was cultivated in 1759 by Mr. Miller; and flowers from april to ſeptember *.

24. This is a herbaceous plant, with filiform, deſcending, ſimple roots. Stem about a foot high, round, ſucculent, ſmooth. Leaves rather large, entire, nerved, ſmooth on both ſides, paler underneath, thickiſh. Petioles longiſh, compreſſed, ſmooth, widening at the baſe. Spikes ſolitary, the length of the leaves, round, thick, with the flowers cloſe. Calyx none, but lanceolate, acute ſcales. Filaments two, very ſhort, at the baſe of the piſtil. Anthers very ſmall, whitiſh. Germ oblong, acuminate. Style ſimple. Stigma acute. It is diſtinct from *P. obtuſifolium*, which has a creeping ſtem.

Native of the higheſt mountains of Jamaica. It flowers in february and march.

25. This alſo is a herbaceous plant, ſmall and bright green. Roots ſmall, capillary, divided, whitiſh. Stem two or three inches high, jointed, diffuſed, round, ſtriated, ſmooth, pellucid, ſucculent, brittle. Branchlets diffuſed, oppoſite to the leaves. Leaves alternate, emarginate at the baſe, entire, veined, green above and ſomewhat hiſpid with pale pellucid briſtles thinly ſcattered over them, dotted, beneath very ſmooth, paler, very tender. Petioles ſhort. Spikes minute, pedicelled, oppoſite to the leaves, ſolitary. Flowers very minute, naked, diſtant. Calyx none, but ſcales ſcarcely viſible at the baſe of the germ. Filaments two by the ſide of the germ at its baſe, very minute, patulous, horizontal, in a manner club-ſhaped. Anthers roundiſh, whitiſh. Germ oblong, hiſpid. Style thick, ſhort. Stigma blunt, brown. Fruit pedicelled, the ſize of a ſmall pin's head, roundiſh, black, ſomewhat hirſute-hiſpid. It is very diſtinct from *P. pellucidum*, in its tenderneſs, leaves, pubeſcence and flowers. The taſte alſo is bitter, not aromatic.

Native of Jamaica, in moiſt woods on the blue mountains. It is an annual plant, and flowers early in the ſpring.

26. This alſo is a herbaceous plant. Root ſmall, annual, ſimple, filamentoſe. Stem three or four inches high, very ſeldom divided, jointed, round, ſcarcely ſtriated, ſomewhat hirſute, having very minute red dots on it, and a ſcattered ſhagginеſs among the petioles, grooved, brittle. Leaves ſmall, on very ſhort petioles, alternate, attenuated towards the top, blunt, entire, veinleſs, nerveleſs, briſtly-ciliate on the upper ſurface towards the edge, ſomewhat ſucculent, ſmooth, pale underneath. Spike terminating, filiform, ſimple. Flowers very minute. Calyx none; but a roundiſh little ſcale covering the germ; by the ſides of which are two filaments, the length of the germ, upright. Anthers roundiſh, twin, white. Germ oblong, attenuated at the baſe. Style none. Stigma villoſe, oblique. Berry on a pedicel three times as long as the germ, containing one ſeed; when ripe it is the ſize of a ſmall pin's head, of a blackiſh colour, and an aromatic flavour.

Native of Jamaica, on the cool mountains, on trunks of trees, eſpecially ſuch as are rotten, hanging down among the moſs, and flowering in ſummer *.

27. Native of South America, in moiſt woods, commonly on the trunks of rotten trees *.

28. Stems ſeveral, a foot and half high, almoſt upright, weak, fleſhy, villoſe, thicker than a quill, round, blood-red, at top flexuoſe and branched; branches alternate, oppoſite or in threes. Leaves petioled, acute, quite entire, thickiſh, flat, villoſe on both ſides and at the edges, dark green above, underneath almoſt veinleſs and very pale green with the edges blood-red; on the middle of the ſtalk the nerves are alſo blood-red; the larger ones are four inches in length; the loweſt are much leſs, and entirely blood-red underneath. Spikes ſmooth, filiform, almoſt upright, green, from one to four inches in length, both ſolitary from the axils, and terminating from two to four, and ſometimes one or two oppoſite to a leaf. Bractes or orbicular pale green ſcales cloſely ſurround the ſpikes, from the upper edge of which come out the ovate germs, bearded at the top, and below the beard is the villoſe brown ſtigma. At the baſe of the germ on each ſide is an antheriferous little bractе.

Native of the Caracas *.

29. This is a ſubherbaceous plant. Stem almoſt ſimple, a foot high, hardiſh, ſlightly flexuoſe, angular, compreſſed, grooved, ſmooth, rigid. Leaves alternate, narrower below, blunt at the tip, quite entire, thickiſh, bright green. Peduncles ſubterminating, axillary, ſolitary, erect; on very long, nearly upright, round ſpikes, ſometimes conjugate. Flowers very minute. It is eaſily diſtinguiſhed by the leaves embracing the ſtem.

Native of Jamaica and other iſlands of the Weſt Indies, on rotten trees, and among the remains of thoſe which have fallen *.

30. Native of the Society iſles *.]

31. This ſends out from the root many ſucculent herbaceous ſtalks almoſt as large as a man's little finger; they are jointed, and divide into many branches, never riſing above a foot high, but generally ſpread near the ground, putting out roots at each joint, propagate very faſt, and ſoon cover a large ſpace of ground. The leaves are very thick and ſucculent; they are about three inches long and two broad, very ſmooth and entire. The pedunele comes out at the end of the branches; this is alſo very ſucculent, and the whole length, including the ſpike, is about ſeven inches. The ſpike is ſtraight, erect, and about the ſize of a gooſe-quill, cloſely covered with ſmall flowers which require a glaſs to be diſtinguiſhed, the whole ſpike much reſembles the tail of a lizard, for which Plumier gave it the name of Saururus.

It is a native of South America, and many of the iſlands in the Weſt Indies: [was cultivated by Mr. Miller in 1739; and flowers from april to ſeptember *.

32. Found at the Cape of Good Hope by Thunberg *.

33. This is a herbaceous plant. Stems very long, crowded, procumbent or declining, rooting, leafy, roundiſh, even. Leaves alternate, quite entire, flat, thickiſh, even. Nerves five, diſtinct at the back of the leaf. Petioles channelled, ſhortiſh, red at the baſe. Spikes filiform, nearly upright, ſometimes hooked, terminating or lateral, oppoſite to the petioles, peduncled, ſolitary or conjugate. The colour of the whole plant is pale green. It is nearly allied to *P. acuminatum*; but differs in having a weak ſtem, very much branched, ſomewhat creeping and rooting; the leaves ovate, acuminate, leſs and not ſo thick; ſpikes ſmaller, ſhorter.

* Swartz deſcr. ᵐ Jacqu. obſ. ⁿ Hort. kew. ᵖ Plumier. ᵠ Jacquin. ʳ Swartz deſcr. ˢ Forſter. ᵗ Hort. kew. ᵘ Linn. ſuppl.

Native of Jamaica and other iſlands of the Weſt Indies; flowering in the ſpring.

Piper ſcandens of the Prodromus is a variety of this.

34. This alſo is herbaceous. Stem puts forth capillary fibres on every ſide; is filiform, ſubdivided, angular, ſmooth, leafy. Leaves alternate, roundiſh, but greater in width than length, retuſe as it were at the baſe, blunt with a very ſhort point, half an inch in breadth, entire, flat, ſomewhat ſucculent, veinleſs, ſmooth on both ſides, paler underneath. Petioles ſhorter than the leaves, ſpreading, round, ſmooth. Spikes peduncled, round, half an inch in length, upright. Peduncles axillary, longer than the leaves, round, ſmooth, ſolitary. Flowers ſo minute as not to be diſtinguiſhed by the naked eye, ſeparated by ovate ſcales. Filaments ſcarcely any. Anthers two by the ſide of the germ. Germ ovate, acute. Style none. Stigmas three. Fruit very minute, ovate, acute, ſeſſile.

It may be diſtinguiſhed from *P. rotundifolium* by the leaves not being orbiculate or ovate; the ſtem not divaricate, but more ſimple and thicker; the leaves underneath pale and thicker; broad-ovate at the baſe, with a very ſhort point.

Native of Jamaica, in rocky woods among moſs.

35. This alſo is herbaceous.[a] Stem filiform, climbing, rooting, divaricate, round, ſucculent. Leaves alternate, entire, ſmooth. Petioles longiſh, reflex. Spikes on the lateral branches pedicelled, oppoſite to the leaves, filiform, an inch long, ſolitary. Peduncles ſhorter than the ſpikes. Flowers very minute, whitiſh. The whole plant has a ſharp taſte. It is very diſtinct from the others in the leaves.

Native of Jamaica, in old woods, on decaying trees.

36. Herbaceous. Stems two or three feet long, ſubdivided, roundiſh, very ſmooth, ſoft. Leaves petioled, alternate, ſmall, ſhining, ſomewhat ſucculent, very minutely hairy on the entire margin. Spikes peduncled, terminating, ſhort. Peduncles ſcarcely longer than the leaves, upright. Flowers hardly diſcernible, whitiſh. It reſembles *P. rotundifolium*, but differs in having a filiform, divaricating ſtem, and orbicular concavo-convex leaves.

Native of the interior of Jamaica on old trees[b].

37. Stems herbaceous, very long, ſubdivided, round, ſucculent, throwing out ſhort capillary fibres on all ſides from the ſtems. Leaves petioled; the lower orbiculate, entire, ſmall, ſmooth, ſomewhat ſucculent, pubeſcent at the edge, with red ſpots below; the upper or terminating ones ſomewhat oblong, ſmooth on both ſides. Spikes terminating, ſhortly peduncled, round, ſolitary, ſmall[c].

Jacquin mentions, that the leaves are greaſy to the touch, bright green, with a peculiar fragrant reviving odour, entitling them to be ranked among the aromatics and cephalics, and which they retain for ſeveral years, when dried; he has ſeen a diſtilled water of them yielding the pleaſant ſcent of the plant.

Native of Jamaica and Martinico, in cloſe moiſt woods, covering the entire moſſy trunks of old trees, and ſtones covered with moſs.

38. Native of Dominica.]

39. This has a pretty thick ſpongy ſtalk fifteen feet high, dividing into many jointed pithy branches. Leaves about a foot in diameter. Spikes ſmall. [This ſpecies is readily diſtinguiſhed by its large, peltate leaves.—Native of Jamaica and Dominica.

40. This holds a middle place between *P. peltatum* and *umbellatum*; but differs from the firſt in its ſubpeltate acuminate leaves; from the ſecond, in its ſubpeltate leaves, and ſmooth ſtem.

Native of Amboina and Baley in woods among the mountains[a].

41. Stem from two to three feet high, climbing, ſubdivided, compreſſed a little, ſmooth, marked with rufous ſpots or dots, ſucculent. Leaves entire, very ſmooth, not fleſhy, three-nerved, paler underneath. Petioles very long, inſerted by little ſheaths into the ſtem. Peduncles terminating or axillary, two-parted. Spikes upright, linear. Stamens and piſtils inſerted ſpirally into the ſpike.

Native of the mountains of Jamaica, Hiſpaniola[b], and Dominica.

42. Root annual. Stem herbaceous, from one to two feet high, round, ſimple, jointed, hoary. Leaves terminating, diſtant, ſpreading, entire, nerved and veined, wrinkled, ſomewhat hirſute underneath, the lobes of the baſe converging forwards; the nerves radiate from the petiole, which is almoſt in the middle of the leaf. Petioles long, round, ſmooth, ſheathing at the baſe, embracing. Spikes axillary, in umbels; umbellets pedate, with from three to ſix ſpikes, on ſhort pedicels, upright, whitiſh. Calyx and corolla none; but roundiſh ciliate ſcales, whence the ſpikes appear ſubtomentoſe to the naked eye. Filaments approximating, two for each ſcale, very ſhort. Anthers roundiſh, white. Germ oblong, longer than the ſcale. Style none. Stigmas three, reflex, thick, black: viſible only with a glaſs[c].

Native of the Weſt Indies. Browne ſays it is very common in the woods of Jamaica, and is ſeldom more than three or four feet high; that the leaves are very large and round, the foot-ſtalks embracing the ſtem at the inſertion; that Piſo affirms the root to be a warm active remedy againſt poiſons, and that a ſyrup is made of it in many parts of our ſugar-colonies, which is much uſed by the inhabitants in colds and catarrhs.

Browne has ten ſpecies of *Saururus*, which he ſeparates from *Piper*; attributing ſix filaments and three piſtils to the former, and two filaments only with three piſtils to the latter.

43. Native of South America.

44. Stems ſubherbaceous, almoſt upright, not rooting, jointed, weak, the thickneſs of a quill, when adult leafleſs, round, a foot high and more, green or dirty purple; the younger ones ſomewhat angular. Leaves on ſhort petioles red above, acute, quite entire, not ſhining, dotted on both ſides, thick, ſomewhat fleſhy, about two inches long. Spikes ſlender, upright, green, about three inches long, on a reddiſh peduncle, an inch in length. Flowers covering the ſpike very cloſely. Below the germ an oblong bracte. It differs from *P. verticillatum* in being much higher, with acute leaves, and a perennial root.—Native of Venezuela.

45. Root perennial, creeping. Stems annual, aſcending at the baſe and then upright, round, panicled, about the thickneſs of a quill, fleſhy, ſmooth, purple, flexible, a foot high. Branches upright. Leaves oppoſite, on the branches three or four, roundiſh or obovate, blunt, thickiſh, underneath very obſcurely three-nerved, there and on the edge ſomewhat villoſe, and pale; but very ſmooth above. Spikes terminating, ſeſſile, from one to four, upright, two inches long, ſlender, round, green. Germ green. Filaments ſhort, brown. Anthers oblong, incumbent, brown or white. The whole plant has an unpleaſant taſte, but ſcarcely any ſmell[d].

Native of the Weſt Indies. Introduced in 1775, by John Fothergill, M. D.[e]

46. Stem half a foot high, herbaceous, ſubdivided, ſtiff, even, thick. Leaves on ſhort petioles, obcordate, a little concave, thickiſh, very ſmooth. Spikes terminating, peduncled, ſolitary, an inch long, round, whitiſh, thickiſh. Peduncles ſhort. Flowers crowded. Calyx and corolla none; only a ſcale. Filaments two, very ſhort. Anthers globular, twin. Germ ovate. Style none. Stigma oblique, villoſe[e].

Native of South America and Jamaica, on very lofty woody mountains.

47. Herb tender, upright, a finger's length. Leaves three, four, or five together, ſucculent, quite entire, petioled. Spikes ſimple, ſeveral times longer than the leaves.—Native of Jamaica[f].

48. This is a herbaceous plant, a foot high and more. Root ſimple, filamentoſe, whitiſh. Stem

[a] Swartz deſcr. [b] Swartz obſ. [c] Willdenow.

[a] Swartz obſ. [b] Idem. [c] Jacquin. [d] Hort. kew. [e] Swartz. [f] Linn. amoen.

round,

round, leafy; pubeſcent, ſometimes ferruginous. Branches oppoſite. Leaves four or five on a petiole, entire, ſmooth, paler underneath, ſcarcely ſuculent: the upper leaves are commonly three, the lower four, ſeldom five. Spikes terminating, long, four or five conjugate, filiform, looſe. Flowers very minute, green. Calyx none; but an ovate, ſmooth ſcale covering the germ; at the baſe of which are two very ſhort filaments. Anthers roundiſh, twin. Germ ovate. Style none. Stigma oblique, villoſe. Berry ſeſſile, oblong.

P. trifolium differs from this in being creeping, with roundiſh leaves. Native of mountain woods in Jamaica[a].

Mr. Dryander believes the *P. ſtellatum* of Swartz to be the ſame with *P. verticillatum*, at leaſt he can ſee no other difference than in the length of the ſpikes, between Browne's ſpecimen of the latter in Linneus's herbarium, and a ſpecimen from Jamaica, in Sir Joſeph Banks's herbarium, which Swartz has marked as his *P. ſtellatum*[b].

Willdenow on the other hand is of opinion, that this differs from the preceding, on account of its acuminate leaves, and the ſpikes being three times as long, and much thicker.

49. Roots long, filiform. Stems filiform, looſe, very long, creeping or pendulous, ſubdivided, angular, channelled, ſmooth, ſpotted. Branches long, four-ſided, jointed. Leaves on very ſhort petioles, ſmaller, obtuſely or obliquely four-ſided, ſpreading horizontally, ſometimes reflex, concavo-convex, veinleſs, thick, ſhining. Spikes pedunculed, terminating, ſolitary, ſhort. Peduncles ſhort. Fructification as in *P. quadrifolium*, *n.* 46.

Native of the Eaſt Indies, on the trunks of old trees. Thunberg found it at the Cape of Good Hope; Solander and Forſter in the South Sea iſlands[c].

50. Native of Jamaica. Found there by Thomas Clark, M. D. Introduced in 1778, by Mr. William Forſyth. It flowers from July to ſeptember[d].

51. Herbaceous. Roots capillary. Stem creeping far and wide, four-cornered, ſmooth, ſtriated and ſpotted. Branches ſhort, aſcending, filiform, looſe, nearly upright, four-ſided, ſpotted, ſmooth. Leaves ſmall, the lower ones oppoſite, deciſſated, in fours at top, linear-oblong, entire, underneath paler and ſpotted with pale red, ſmooth on both ſides. Petioles ſhortiſh. Spikes terminating, pedunculed. Peduncles upright, ſolitary, terminating, the length of the leaves, round, ſmooth. Calyx none; but a roundiſh ſcale. Filaments two, very ſhort, at the ſides of the ſcale. Anthers twin. Germ oblong, covered with the ſcale. Style none. Stigma villoſe. Berry oblong, minute.

Native of Jamaica, among moſs, at the roots of trees, on the high mountains[e].

According to Willdenow, this is very nearly related to the preceding.

52. Branches ſmooth, jointed, rounded below, above a little angular, ſlightly ſtriated. Joints knobbed. Leaves alternate, gradually attenuated towards the outſide, acute, ſmooth, paler underneath. Petiole ſhort, keeled. Spikes oppoſite to the leaves, pedunculed, ſolitary, ſtraight, three inches long. Peduncles the length of the petiole. Berries diſtinct, the ſize of a muſtard-ſeed, ovate, four-cornered, acuminate.

Found in the iſland of Trinidad by Ryan.

53. Stem ſhrubby, round, ſmooth, even. Joints equal. Leaves three or four inches long, exactly cordate, even, with the veins not much branched. Petioles equal. Spikes pedunculed, oppoſite to the leaves, about three inches in length, ſlender. Peduncle ſhorter than the petiole. Flowers very much crowded together. It differs from *P. reticulatum* in having the leaves exactly cordate, with a deep ſinus at the baſe, and the lobes more diſtant. It recedes alſo from Plumier's figure of *P. decumanum*, both in the form of the leaves, and thickneſs of the ſpikes, as alſo in the greater ſlenderneſs of the ſtem and branches.—Native of Braſil.

[a] Swartz deſcr. [b] Linn. tranſ. 2. 215. [c] Swartz obſ. [d] Hort. kew. [e] Swartz deſcr.

54. Branches ſmooth, ſtraight, round at bottom, angular at top, jointed, with the help of a glaſs having a mealy appearance. Joints knobbed. Leaves alternate, five or ſix inches long, ſharp at the tip, ſomewhat wrinkled, eſpecially underneath from the protuberant veins. Petioles ſhort, channelled above, ſharply keeled underneath. Spikes oppoſite to the leaves, pedunculed, ſolitary, half an inch long, probably longer as they advance in age, round, terminated by a ſhort point without flowers. Peduncles the length of the petiole.—Found in Cayenne by von Rohr.

55. Branches round, ſmooth: the joints a little broken, an inch and half long. Joints knobbed. Leaves alternate, with very ſlender veins and many nerves, paler underneath, with the nerves ſtanding a little out, bluntiſh at the baſe and tip. Petiole ſhort, ſimple, channelled above, ſharply keeled underneath. Spikes oppoſite to the leaves, peduncle[f], an inch and half long, round, blunt; when young a little curved, when more advanced ſtraight. Peduncle the length of the petiole.—Found in the iſland of Montſerrat by Ryan.

56. Branches round, ſmooth, knobbed at the joints. Leaves alternate, remote, quite entire, very finely obliquely and remotely many-nerved, ſomewhat veined, a little paler underneath, ſharp, five or ſix inches long. Petiole very ſhort. Spike oppoſite to a leaf, pedunculed, four or five inches long, ſpreading, the ſize of a ſmall packthread, curved back at the tip. Peduncle twice as long as the petiole. Flowers crowded together very cloſe. It ſeems to be allied to *P. nitidum* of Swartz.—Native of Surinam.

57. Stem branched. Branches diffuſed, rooting, ſmooth, the ſize of a ſmall packthread, alternate, except that ſometimes the loweſt are oppoſite, brown. Leaves petioled, ſmall, ſharp at the baſe, obſcurely three-nerved, veinleſs. Spike at the end of the branches, ſolitary, ſtraight, three inches long, the ſame thickneſs with the branches, round, pedunculed. It differs from *P. cordatum* of Swartz, and *P. retuſum* of Linneus, in having three leaves at each joint. It approaches to the figure of *P. trifoliatum* in Plumier; but differs in having emarginate leaves, acute at the baſe. Perhaps it is only a variety?—Found in the iſland of Montſerrat by Ryan.

58. Stem branched. Branches dichotomous, round, ſtriated above, appearing ſlightly pubeſcent towards the top when magnified, often flexuoſe; the internodes two or three inches long; the joints knobbed. Leaves three inches long, ſharp at both ends, even, obſcurely veined above, very finely veined underneath. Petioles very ſhort, equal, ſimple. Peduncles oppoſite to the leaves, a little longer than the petiole. Spikes ſcarcely longer than the peduncle. It approaches to *P. rugoſum*, but the leaves are ſmaller, very ſmooth and even on the upper ſurface, veined indeed underneath, but not wrinkled as in that, ſharp at the baſe, peduncles ſhorter than the petiole.—Found in Cayenne by von Rohr.

59. Branches ſtriated, ſmooth, the thickneſs of a gooſe quill; joints knobbed, internodes three or four inches long. Leaves alternate, the lower ones ſubcordate at the baſe, half a foot long, ſix or ſeven inches wide, tender, even on both ſides; nerves oblique, bowed; the lower ones oppoſite, the reſt alternate, veined, pale green; the uppermoſt a little narrower on one ſide, and running down obliquely towards the baſe. Petiole an inch long, without any appendicle. Peduncle oppoſite to the leaf, ſhorter than the petiole. Spikes longer than the internodes, three or four inches long, the thickneſs of a packthread. Flowers very minute. It differs from *P. macrophyllum* in there being no appendicles to the peduncles.—Gathered by von Rohr at St. Martha[g].

60. This is a ſhrub five or ſix feet high. Stem upright, round, ſomewhat rugged. Branches ſpreading, round, jointed, rugged. Leaves alternate, many-nerved, veined: nerves rigid, on the lower ſurface more raiſed. Petioles ſhort, round. Peduncles oppoſite

[f] Vahl eclogæ.

poſite to the leaves, ſhorter than the petioles, thick, round, rugged, ſolitary. Spikes two inches long, cylindrical. Flowers crowded. Calyx none; but a minute, roundiſh ſcale, at the ſides of which are two very ſhort filaments. Anthers very minute, roundiſh, twin. Germ ovate. Styles none. Stigmas three, recurved, permanent. It differs from *P. adunctum*, which it reſembles very much, in having wider leaves, browniſh-green not paler; and upright not hooked ſpikes.

Native of Jamaica, in the mountains of the more temperate part*.

Mr. Miller has thirteen ſpecies, all American, except *P. Siriboa*, which is a native of the Eaſt Indies. His ſpecies are chiefly the *Saururi* of Plumier, with three found by Houſtoun. He has not mentioned the common Eaſt-Indian Peppers, having probably never cultivated them.

He has the following ſpecies not mentioned above.]

1. Piper humile.
   Mill. dict. n. 4.
   P. longum humilius, fructu e ſummitate caulis prodeunte. *Sloan. cat.* 45.
   Saururus. *Brown. jam.* 204. 4.
   Leaves lanceolate nerved rigid ſeſſile.
2. Piper laurifolium.
   Mill. dict. n. 6.
   Saururus fruteſcens, lauroceraſi folio, fructu breviore & craſſiore. *Houſt. MSS.*
   Leaves lanceolate-ovate nerved, ſpikes ſhort.
3. Piper tomentoſum.
   Mill. dict. n. 7.
   Saururus arboreſcens latifolia villoſa, fructu gracili. *Houſt. MSS.*
   Leaves ovate-lanceolate tomentoſe, ſtem arboreſcent.
4. Piper decumanum.
   Mill. dict. n. 9.
   Saururus fruteſcens plantaginis folio ampliore, fructu breviore & graciliore adunco. *Houſt. MSS.*
   Leaves cordate-ovate nerved acuminate, ſpikes reflex.
5. Piper glabrum.
   Mill. dict. n. 12.
   Saururus racemoſus, ſ. botryoitis minor. *Plum. cat.* 51.
   Leaves ovate-lanceolate acuminate ſmooth three-nerved.
6. Piper racemoſum.
   Mill. dict. n. 13.
   Saururus racemoſus, ſ. botryoites major. *Plum. cat.* 51.
   Leaves lanceolate-ovate wrinkled, nerves alternate.

DESCRIPTIONS, &c.

1. Stalks ſlender, frequently trailing, and putting out roots from the joints. Leaves five inches long, and two broad in the middle, drawing to a point at each end; they have one ſtrong midrib, with ſeveral veins on the under ſurface, running from the midrib to the ſides. Spike very ſlender, five inches long.—Native of Jamaica.

2. Stalks ſhrubby, jointed, nine or ten feet high, dividing into ſmaller branches. Leaves ſeven inches long and three broad, ending in acute points; they are veined and rough, of the ſame conſiſtence with Laurel leaves. Spikes from the ſides of the branches at the joints, oppoſite to the leaves, not more than an inch and half long, the thickneſs of a ſmall quill, cloſely ſet with flowers.—Native of Vera Cruz in America.

3. This has hollow pithy ſtalks, twelve or fourteen feet high, dividing into many crooked branches, having ſwelling joints. Leaves five inches long and three broad, having many veins, and covered with a woolly down. Spikes from the ſides of the branches oppoſite to the leaves, ſlender, and about three inches long, turning downwards.—Diſcovered by Dr. Houſtoun at Vera Cruz.

4. This riſes with ſeveral ſhrubby ſtalks fifteen feet high, dividing into many ſlender branches, with protuberant joints. Leaves five inches long and three broad, ſmooth, and at their baſe have five veins, but the two outer join the borders of the leaves ſoon; the other three run to the top, the middle one in a right line; the two ſide ones diverge, and join at the top: they are of a dark green on their upper ſide, but pale on their under. Spikes from the ſides of the branches; extremely ſlender, an inch and half long.—Sent from Carthagena by Dr. William Houſtoun.

5. This has many ſhrubby ſtalks ten feet high, dividing into many crooked branches towards the top, having ſwelling joints. Leaves near four inches long, and two and a half broad, of a lucid green, with three large veins or nerves, the middle one ſtraight, the two outer diverging towards the ſides in the middle of the leaf, but drawn together again at the point. Spikes from the ſides of the ſtalks oppoſite to the leaves, pretty long, ſlender, and a little incurved.—Sent from Campeachy by Dr. Houſtoun.

6. Stalk ſhrubby, ten or twelve feet high, dividing towards the top into a great number of ſmall branches, which are hollow, and having protuberant joints. Leaves five inches long, two inches and a half broad, ſome having long, others very ſhort foot-ſtalks; they are of a deep green on their upper ſide, but pale on their under, ending in acute points. Spikes from the ſide of the ſtalks oppoſite to the leaves, long and ſlender, cloſely ſet with very ſmall flowers.—Native of Campeachy.

PROPAGATION AND CULTURE.

All theſe plants require a warm ſtove to preſerve them in England. They may be propagated by ſeeds, if they can be procured freſh from the countries where the plants grow naturally; theſe ſhould be ſown upon a good hot-bed in the ſpring, and when the plants come up and are fit to tranſplant, they ſhould be each put into a ſeparate ſmall pot filled with light freſh earth, and plunged into a hot-bed of tanner's bark, ſhading them every day from the ſun till they have taken freſh root; then they muſt be treated in the ſame way as other tender exotic plants, admitting freſh air to them daily in proportion to the warmth of the ſeaſon, to prevent their drawing up weak; and when the nights are cold, the glaſſes of the hot-bed ſhould be covered with mats to keep them warm. As the ſtalks of moſt of theſe plants are tender when young, they ſhould not have much wet, which would rot them; and when water is given to them it muſt be with caution, not to beat down the plants; for when that is done, they ſeldom riſe again.

In autumn the plants muſt be plunged into the tan-bed of the bark-ſtove, and during the winter they muſt be ſparingly watered; they require the ſame warmth as the Coffee-tree. In the ſummer they require a large ſhare of freſh air in hot weather, but they muſt be conſtantly kept in the ſtove, for they are too tender to bear the inclemency of our weather in ſummer.

[1. *Black Pepper.*

From Dalrymple's Orient. Repert. I.

The introduction of this valuable plant into cultivation in the Circars, was effected by Dr. William Roxburgh in 1787. He found that the Black Pepper grew wild in the hills fifty miles to the N. of Samul Cotah, about 17° N. Lat. and 82° E. Long. from Greenwich*. (See Marſden's Sumatra.)

For prop-trees he uſed Erythrina Corallodendron, called Moochy Wood-tree, or Muricu.

In 1788 he had completed three plantations containing 4750 prop-trees, with two Pepper-vines to each; and had beſides about 10,000 plants in the nurſeries. The trees were ſet in quincunx order, at ſix, eight and ten feet aſunder. One thouſand plants will yield from 500lb. to 1000lb.

In 1789 his plantations contained between forty and fifty thouſand Pepper-vines, occupying about fifty acres of land. The ſoil they thrive beſt on, is a mixture of red clay and ſand.

Method of planting and cultivating the Pepper Vines at Tellicherry, on the Malabar coaſt.

The Pepper-vine ſhould be planted in a low firm ground. In the beginning of June, when the rain falls inceſſantly, at the foot of a Jack, Mango, Cajou,

* Swartz deſcr.

* About thirty miles among the hills, at a place called Rumphah. It grows wild not only there, but in almoſt every valley among theſe hills.

Muricu, or any other tree, whoſe bark is rough or prickly, dig a hole one foot deep, the breadth and length ſix inches; into this hole put a piece taken from the extremity of one of the branches of a Pepper-vine; then fill it up with earth, taking care no water is therein, and that none may remain after planting; in the month of july the roots will extend themſelves in the ground, and the ſprouts will appear on the ſurface, when they are to be tied to a tree, and a circular bank of earth thrown up round them, that they may enjoy the moiſtneſs of the water which remains on the ground, and thereby kept from being inflamed by the heats, which ſubſiſt from the month of july till october; when the rains are over, cover the root of the vine with freſh leaves, it matters not from what tree, ſo they have the quality of cooling: if the ground is too dry, water the ſame, morning and evening; but if it is entirely cool, twice in eight days is ſufficient: then plant five or ſix ſprigs at the foot of the ſame tree, taking particular care they no ways touch one another.

Ten days after the rains are ſet in, remove the leaves that cover the root of the vine, pull up the grais that may have grown near them, and demoliſh the circular bank of earth, made to contain the water, that none may remain at the foot of the tree; in the month of auguſt repeat the ſame. The vines are to be cherifhed in this manner for three years.

It muſt be obſerved, that the foot of the vines ſhould be covered every year, in the manner before mentioned.

If the vine is once ſmothered by the heat, it will begin to languiſh and produce no fruit, ſo it is neceſſary to follow the above inſtructions.

The leaves ought likewiſe to be removed in the month of june, to prevent the white ant from eating the root of the vine, thoſe vermin being much given to eat the leaves, which the rain draws into the ground, and thereby come to the roots of the vine, which they prey upon likewiſe.

Obſerve alſo, that the vine is not too much affected by the heat of the ſun, on account of the proximity of the water.

Theſe Pepper-vines ought not to be planted at the foot of trees whoſe bark is ſmooth, as they will in conſequence fall to the ground: therefore always make choice of thoſe that are rough and prickly.

The manner of planting the Pepper-vine in the month of february, where the ground is low and firm.

Having made a hole ten inches from the tree, the depth thereof being fifteen inches, the length and breadth twelve inches each, take ſeven branches from the extremity of the vine, cut them thirty inches long, and put them into the hole; then fill it three-fourths with earth, and the remainder with freſh leaves, obſerving to put water thereon, morning and evening, till the commencement of the rains, when fill the hole with earth, and throw up the bank as before directed. The time for planting thoſe vines, in the rainy ſeaſon, is in the month of june, and the month of february in the dry ſeaſon: if they are planted at any other time they will bear no fruit; the reaſon is, that they will extend their roots in the ground at theſe times, and no other, and therefore particular care ought to be taken of them, as before directed.

Trees, planted for the ſupport of Pepper-vines, ought to be fifteen or ſixteen feet aſunder; if cloſer, the branches will ſhade the vines from the ſun, as they ought to receive a moderate heat.

Manner of planting the Pepper-vine in higher ſituation and firm ground.

Make a ſquare hole of fifteen inches, the ſame diſtance from the tree; take ten branches from the extremity of the vine, of ſeven inches length each, put them into the hole at a certain diſtance, filling it with earth, and treating them as before directed. In a high place, the trees planted for the ſupport of Pepper-vines, ought not to be more than thirteen feet diſtant on account of the heat. Two years after they are planted, it is neceſſary to throw up a ſquare bank of earth round every five plants, that the rain-water may ſoak in, and nouriſh the roots; if this is omitted during the rains, the vine will not ſubſiſt during the dry ſeaſon, on account of the heat.

This ſquare is to be repaired every three years, by which means the vines will live a long time, and produce plenty of Pepper: it ought to be done during the rains, in the month of july, for, at that time, ſhould the ſpade happen to touch the root, it will be of no inconvenience, but ſhould it do ſo at any other time, the vine will certainly die.

The manner of planting Pepper-vines in very high grounds.

Make a ſquare hole two feet and a half deep, at the ſame diſtance from the tree, take twelve ſlips from the extremity of one of the vines, two feet nine inches long, put them into the hole at a certain diſtance, and cover them as before directed, throwing up the ſquare bank. It is neceſſary to plant thoſe vines at the time before mentioned. The reaſon for making the hole deeper, is on account of the great heats which prevail in high places, to prevent the vine from dying.

Vines, planted in ſtony ſoil, will not produce any fruit, becauſe the roots cannot extend themſelves with facility.

A ſandy ſoil is equally prejudicial to them, becauſe it is naturally hot, and the heat of the ſun penetrates with more facility than in any other ground, conſequently the vines are not able to reſiſt, though watered three or four times a day.

You may plant vines in a place where freſh water communicates itſelf in the ſame manner as in ground entirely low and firm, but I doubt very much if they will produce Pepper; if they really yield any, I am certain the grapes will be of no great account, becauſe of the continual moiſture the plant will receive. I have already remarked, it is abſolutely neceſſary that thoſe vines enjoy an equal degree of heat and moiſture, if you think of gathering a good crop.

Manner of planting the Pepper grain.

Take ripe Pepper and put it into water for three days, at the end of which take off the ſkin, and after you have mixed good red earth, with cow-dung and water, put the Pepper into it, expoſing the ſame to the ſun for three days, only early in the morning and evening; it is neceſſary this mixture be neither too thick or thin. After this, plant the ſame in an earthen pot, every grain at a certain diſtance, taking care to water them every day, with a water-pot, until the ſtalk has four leaves; then dig a hole at the foot of a tree, two feet deep and nine inches long and broad, take cow-dung and aſhes of all ſorts of fire-wood, put it in the hole, and mix the ſame with ground dug out of it, taking care to fill it in ſuch a manner that there only remains five inches of elevation; fifteen days after, plant four Pepper-vines in every hole, cover them with earth two inches deep; during the ſummer water them every day, morning and evening, and cover them during the rains; likewiſe take care no water remains at their feet, by covering them with earth, as they ought to be; as ſoon as the rains are over, throw up a circular bank of earth round them, to contain the water they are watered with; in this manner they muſt be nouriſhed for three years, in the fourth year they will begin to give fruit.

Theſe inſtructions are to be followed every year; theſe Pepper plants are planted either in high or low ground, but it is neceſſary it be very firm.

Manner of planting Pepper-vines where ſalt water is.

After having made a hole thirteen inches ſquare, at the foot of a tree, fill the ſame half up with good red earth, without mixing it in the leaſt with ſalt water, then plant therein ten ſlips of thoſe vines, at a certain diſtance, and cover the ſame with good red earth; when the rains are over, throw again red earth at their feet, and make a circular bank round them, to form a conſervatory for watering them every other day, taking particular care to cover the feet of the branches with freſh leaves: in the beginning of the rains till the

conſervatory,

conſervatory, and take away the leaves, obſerving to pull up the graſs that ſprouts at their feet, covering them with red earth, at the ſame time ſpreading ſome round about; they are to be notriſhed every year, as is pointed out at the beginning of thoſe inſtructions.

Signed M. Firth.

Dr. Anderſon adds that the vines generally bear fruit every fourth year, but often in the third, if ſoils and ſeaſons are favourable. The flowers appear in june, and the berry is ripe in ſeptember. It is cut down when the berry is blood-red, dried in the ſun five or ſix days, winnowed and ſorted. White Pepper is prepared by bruiſing the berry with the feet, ſo as to take off the outer ſkin, waſhed with water, and afterwards dried in the ſun.

According to Mr. Marſden, in his hiſtory of Sumatra, (p. 107.) the ground choſen there for a Pepper-garden, is marked out into regular ſquares of ſix feet, the intended diſtance of the plants, of which there are uſually a thouſand in each garden. The next buſineſs is to plant the chinkareens, which ſerve as props to the Pepper-vines, and are cuttings of a tree of that name, which is of quick growth. When the chinkareen has been ſome months planted, the moſt promiſing upright ſhoot is reſerved for growth, and the others lopped off; this ſhoot having acquired two fathoms in height, is deemed ſufficiently high, and its top is cut off. Two Pepper-vines are uſually planted to one chinkareen, round which the vines twiſt for ſupport, and after being ſuffered to grow three years, by which time they are eight or twelve feet high, they are cut off about three feet from the ground, and being looſened from the prop are bent into the earth in ſuch a manner that the upper end is returned to the root. This operation gives freſh vigour to the plants, and they bear fruit plentifully the enſuing ſeaſon. The fruit is four or five months in coming to maturity: the berries are at firſt green, turn to a bright red when ripe, and ſoon fall off if not gathered in proper time. As the whole cluſter does not ripen at the ſame time, part of the berries would be loſt in waiting for the latter ones; the Sumatrans therefore pluck the bunches as ſoon as any of the berries ripen, and ſpread them to dry upon mats, or upon the ground. By drying they become black, and more or leſs ſhrivelled, according to their degree of maturity.

13. No plant is cultivated with ſo much care and aſſiduity in the South Sea iſlands as the intoxicating Pepper or Ava. The ground is dug over ſeveral times and well cleared from weeds, and then it is manured with ſhell or coral lime *.]

23. If the ſeeds are permitted to ſcatter, the plants will come up without trouble; or if the ſeeds are ſaved, and ſown upon a hot-bed in the ſpring, the plants will riſe eaſily. Tranſplant theſe into ſeparate pots, and plunge them into a hot-bed of tanner's bark; treating them as other tender plants; but they ſhould not have much wet.

31. Seeds of this are rarely produced in England; but it increaſes very faſt by the ſtalks, which put out roots; as do many other ſpecies. It ſhould have little wet, eſpecially in winter. If the plants are plunged into the tan-bed in the ſtove, the ſtalks will ſtrike new roots into the tan, and may be cut off to make new plants.

[This will alſo apply to ſeveral other ſorts. Moſt of them will alſo grow by cuttings, laid a few days in the ſhade to dry, being of a ſucculent nature.

DESCRIPTIONS, *&c.*

1. This riſes with a ſtem to the height of twenty-five feet or more, almoſt as large as a man's body, covered with a light-coloured ſmooth bark, and ſending out ſeveral branches at the top without order. Leaves pinnate, with ſeven leaflets for the moſt part, two inches long, and one inch and a half broad, commonly oppoſite. Flowers of a dirty white colour, ſucceeded by oblong pods, which have four longitudinal wings, and are jointed between the cells.

[Swartz deſcribes it as a middle-ſized tree, with an unarmed trunk, and ſpreading branches. Leaflets quite entire, pubeſcent, deciduous. Racemes thyrſoid, terminating, many-flowered, with decuſſated branchlets. Flowers peduncled, numerous, rather large. Calyx goblet-ſhaped, five-cleft, unequal, of a duſky-purpliſh colour, hoary; the two upper ſegments ſcarcely divided, the three lower ovate, the middle one acute. Banner of the corolla roundiſh, compreſſed, covering the wings and keel, keeled at the back: wings ovate, clawed, oblique, white with blood-red veins: keel curved in, gibbous, bifid, blood-red at the tip. Germ ſtriated, pubeſcent: ſtyle curved in, awl-ſhaped. Legume membranaceous, compreſſed; the wings not lateral, but marginal in pairs. Seeds roundiſh.

This tree is a native of Jamaica, and grows chiefly in the low lands (by way ſides, *Jacqu.* on dry calcareous hills, *Swartz*) where it generally riſes to the height of twenty or thirty feet; ſometimes more. It flowers about may or june (march and april, *Swartz*) and throws out all its bloſſoms before the appearance of the foliage; (or ſometimes with it, *Jacqu.*) but the leaves ſucceed pretty ſoon. The bark of the root (leaves and twigs, *Jacq.*) is uſed for the ſame purpoſes, and with the ſame effects, as the leaves and branches of Surinam poiſon; (Cytiſus 2. 296.) it is pounded, and mixed with the water, in ſome deep and convenient part of a river or creek, whence it may ſpread itſelf; in a few minutes the fiſh, that lie hid under the rocks or banks, riſe to the ſurface, where they float as

if they were dead; moſt of the large ones recover after a time, but the ſmaller fry are deſtroyed. The eel is not intoxicated with common doſes, though it is affected very ſenſibly; for the moment the particles ſpread where it lies, it moves off with great agility. Jacquin obſerves, that this quality of intoxicating fiſh is found in many other American plants.

This is generally conſidered as one of the beſt timber-trees in the iſland. The wood is very hard and reſinous; and laſts almoſt equally in or out of water. It is of a light brown colour, coarſe, croſs-grained and heavy [9].

It makes excellent piles for wharfs. The ſtakes ſoon form a good live fence. The bark of the trunk is very reſtringent; a decoction of it ſtops the immoderate diſcharge of ulcers, eſpecially when it is combined with the Mangrove bark; it cures the mange in dogs; and would probably anſwer well for tanning leather [9].

It was cultivated in 1690, in the Royal Garden at Hampton Court [1].]

2. This differs from the firſt in the ſhape and conſiſtence of the leaves, which are more oblong and of a firmer texture; in other reſpects they are very ſimilar.

Native of the Weſt Indies. [Jacquin found it on the coaſt in woods, near Carthagena.

He remarks that it has the habit of the preceding, but that it is double the ſize in all its parts. The leaflets are obovate and very blunt, ſometimes with a point and ſometimes without. It ſeems never to have flowered in Europe. Plumier's ſynonym, which Linnæus attaches to the firſt, Jacquin gives to the ſecond ſpecies.]

PROPAGATION AND CULTURE.

Both ſorts are equally propagated by ſeeds, when they can be obtained freſh from the countries where they naturally grow, for in Europe theſe plants do rarely flower; there are plants now in the Chelſea Garden which are more than twenty years old, and if they had not been two or three times ſhortened, would have been more than twenty-five feet high, yet have not attempted to flower though they are in perfect health.

The ſeeds muſt be ſown upon a good hot-bed in the ſpring, and when the plants come up and are fit to tranſplant, they ſhould be each planted in a ſmall pot filled with light earth, and plunged into a hot-bed of tanner's bark, and afterward treated in the ſame way as hath been directed for the ERYTHRINA.

DESCRIPTIONS, *&c.*

1. The male plants of the prickly Piſonia differ ſo much in appearance from the female, that thoſe who have not ſeen them riſe from the ſame ſeeds, would ſuppoſe they were different ſpecies, I ſhall therefore give ſhort deſcriptions of each.

The male plants have ſtalks as thick as a man's arm, which riſe ten or twelve feet high; the bark is of a dark brown colour, and ſmooth; theſe ſend out many branches by pairs oppoſite, which are much ſtronger than thoſe of the female, and do not hang about ſo looſe. They are garniſhed with obovate ſtiff leaves, an inch and a half long, and an inch and a quarter broad, ſtanding oppoſite on ſhort foot-ſtalks. From the ſide of the branches come out ſhort ſpurs, like thoſe of the Pear-tree, having each two pairs of ſmall leaves at bottom, and from the top comes out the peduncle, which is ſlender, about half an inch long, dividing at the top into three; each of theſe ſuſtain a ſmall corymb of herbaceous yellow flowers, each having five ſtamina ſtanding out beyond the petal, terminated by obtuſe anthers.

The ſtalks of the female plants not being ſo ſtrong as thoſe of the male, require ſupport. Theſe riſe eighteen or twenty feet high, ſending out ſlender weak branches oppoſite, which are armed with ſhort, ſtrong, hooked ſpines, and have ſmall oval leaves, about an inch and three quarters broad; theſe ſtand oppoſite on the larger branches, but on the ſmaller they are alternate, and have ſhort foot-ſtalks. The flowers are produced in ſmall bunches at the end of the branches, ſitting upon the germ; they are ſhaped like thoſe of the male, but have no ſtamina; in the center is ſituated a cylindrical ſtyle, crowned with five ſpreading ſtigmas. The germs afterwards turn to a channelled, five-cornered, glutinous capſule, armed with ſmall crooked ſpines, each containing one oblong, oval, ſmooth ſeed.

[Jacquin deſcribes it as an inelegant tree, with round, reclining branches, wanting ſupport. Spines awl-ſhaped, acuminate, axillary, oppoſite, perpendicular to the branch, ſtrong, recurved at the points. Leaves oval, acute, quite entire, ſmooth, petioled, oppoſite. Racemes corymbed, branched, axillary and terminating, not reaching beyond the leaves, but when in fruit very much elongated. Flowers ſmall, numerous, yellowiſh green, ſupported by three awl-ſhaped bractes, if the flower terminates the branchlet of the raceme, but with two only, if it is placed at the ſide of it, the raceme itſelf then ſerving for the third.

Jacquin obſerved many plants of this ſpecies about Kingſton in Jamaica, where they are abundant, and always

[9] Browne. [1] Long. 824. [2] Hort. kew.

always traced the hermaphrodite and female flowers to different individuals.

Browne affirms that the flowers are very various; being ſometimes hermaphrodite on every branch, ſometimes male in one branch and female in another, and ſometimes male, female and hermaphrodite on the different parts of the ſame plant; but moſt commonly they are all of one kind. It is a ſtrong withey climber, the main trunk being ſometimes no leſs than five or ſix inches in diameter; but this is generally in the woods, where it thrives beſt, and is commonly ſupported by the help of ſome of the neighbouring trees. It is frequently cut for hoops, when there is a ſcarcity of other wood.

Gærtner deſcribes the fruit as a ſuperior capſule, oblong, blunt, five-cornered, coriaceous, muricate with little barbed glutinous prickles, in a double row at the angles; it is of a very dark brown colour, one-celled and valveleſs. Seed oblong, roundiſh, ſlightly attenuated downwards, ſtriated, having a depreſſed longitudinal groove on one ſide, of a very dark colour. A briſtle-ſhaped cord connects the top of the ſeed and of the capſule. Skin of the ſeed ſingle, membranaceous, dry, thin. Albumen central, cylindrical, marked with a deep groove, farinaceous, very white. Embryo the ſize of the ſeed, yellowiſh: lobes leafy, rolled longitudinally into a cylinder about the albumen, and incloſing it entirely: radicle conical, ſhort, inferior.—The capſule is certainly valveleſs, though Linneus deſcribed it otherwiſe, being miſled by Plumier's figure. Jacquin remarked only a ſingle row of barbed prickles, in the plants from Domingo.

In Jamaica it is called Cock's-ſpur or Fingrigo. Mr. Miller cultivated it here in 1739. It flowers in march and april.]

This plant is very common in the ſavannas, and other low places in the iſland of Jamaica, as alſo in ſeveral other iſlands in the Weſt Indies, where it is very troubleſome to whoever paſſes through the places of their growth, faſtening itſelf by the ſtrong crooked thorns to the clothes; and the ſeeds being glutinous and burry, alſo faſten themſelves to whatever touches them: ſo that the wings of the ground-doves and other birds, are often ſo loaded with the ſeeds, as to prevent their flying, by which means they become an eaſy prey.

[2. Native of Antigua.

3. Swartz refers the *P. inermis* of Jacquin to this ſpecies. Jacquin deſcribes it as a ſmall tree without thorns, upright, twelve and ſometimes twenty feet in height, with a trunk five inches in diameter: when it grows in thick coppices it acquires an inelegant habit, not much unlike the firſt ſpecies. Leaves oblong-lanceolate, acuminate. Racemes like thoſe of the prickly ſort, but not elongated when in fruit; continuing after the fruit is fallen, and then becoming red. Bractes the ſame. Flowers ſmall, greeniſh yellow, having a ſlight odour. Berry black, ſoft, containing a whitiſh pulp, which is often wanting, being probably eaten by inſects, for it is always found in the unripe fruit. This tree does not at all agree with that which is figured in the *Hortus Malabaricus*, under the name of *Katu-kara-walli*; for it is prickly. *P. inermis* of Jacquin is common in the woods and coppices about Carthagena in New Spain. Swartz found his *P. nigricans* in Jamaica.

4. Native of Hiſpaniola.

5. This ſpecies reſts on the authority of Ammann. The figure in *Hortus Malabaricus* cannot be this ſpecies, being thorny. Swartz refers the *P. inermis* of Jacquin to his *P. nigricans*, *n.* 3. which ſee.

According to Linneus, it is a native of the Eaſt Indies. Forſter aſcribes it to the Society iſlands.]

PROPAGATION AND CULTURE.

In Europe this plant is preſerved in the gardens of ſome curious perſons for variety; it is propagated by ſeeds, which ſhould be ſown in pots filled with light rich earth, and plunged into a hot-bed of tanner's bark; and when the plants come up, they ſhould be tranſplanted into ſeparate pots, and plunged into the hot-bed again, where they may remain till Michaelmas, when they ſhould be removed into the ſtove, and plunged into the bark-bed, and treated in the ſame manner as has been directed for ſeveral tender plants of the ſame country; obſerving in hot weather to give them plenty of water, but in winter they ſhould have it more ſparingly. They are too tender to thrive in the open air of this country at any ſeaſon of the year, wherefore they ſhould be conſtantly kept in the ſtove. They retain their leaves moſt part of the year in England.

Common Maſtick Tree.

β. Piſtacia maſſilienſis *Mill. dict. n.* 6.

Terebinthus anguſtifolia maſſilienſis. *Tourn. H. R. par.*

Narrow-leaved Maſtick Tree.

Leaves abruptly pinnate, leaflets lanceolate.

DESCRIPTIONS, *&c.*

1. In the Levant, where the Piſtacia is a native, this tree grows to the height of twenty-five or thirty feet; the bark of the ſtem and old branches is of a dark ruſſet colour, but that of the young branches is of a light brown. The leaves in the *vera* of Linneus (n. 3.) are compoſed of two or three pairs of leaflets, terminated by an odd one; they approach towards an ovate ſhape, and their edges turn back: in the *trifolia* of Linneus, the leaves, for the moſt part have three, but ſometimes four ovate leaflets, of a dark green colour: and the *narbonenſis* has three or five roundiſh leaflets, of a light green colour. The leaves in all theſe, which ſeem not to be diſtinct ſpecies, emit an odour like that of the nut, when they are bruiſed. Some of the trees produce male flowers, others female; and ſome, when they are old, have both on the ſame tree. The male flowers come out from the ſide of the branches in looſe bunches, and are of an herbaceous colour. The female flowers come out in the ſame manner in cluſters.

[Mr. Swinburn obſerves, that the male tree of the Piſtacia (trifolia. *Lin.*) has ſmall oblong blunt leaves, of a duſky green; the flowers thick and in bunches; the female bloſſoms are more ſcattered, the leaves larger, harder, rounder, and of a lighter colour. The male puts forth its flowers firſt, and ſome gardeners pluck them whilſt yet ſhut, dry them, and afterwards ſprinkle the pollen over the female tree: but the method uſually followed in Sicily, when the trees are far aſunder, is to wait till the female buds are open, and then to gather bunches of male bloſſoms ready to blow; theſe are ſtuck into a pot of moiſt mould, and hung upon the female tree, till they are quite dry and empty. This operation is called *tuchiarare*, and never fails to produce fructification; ſometimes the gardeners ingraft the male bud upon the female tree. The male tree is called in the Sicilian language *Scornabecce*, and the fruit *Faſtuge*[a]. Our old writers call it *Piſticke nut.*

Though one variety of the Piſtacia tree has the appelative of *narbonenſis*, and P. trifolia is ſaid to be a native of Sicily, yet there is no doubt of its having originally been brought into Europe, with moſt of our valuable fruits, from the eaſtern countries. Pliny relates, that the Emperor Vitellius introduced it into Italy from Syria, when he was Legate in that province.

Gouan thus diſtinguiſhes the three ſpecies or rather varieties of the Piſtacia tree.

[a] Travels in the Two Sicilies, vol. 2. p. 255.

1. *P. trifolia* has two or three flowering buds from the ends of the branches, below the branching bud. Theſe have no leaves. Racemes compound, naked or leafleſs. The branching bud puts forth pubeſcent, almoſt ſilky leaves, the firſt ternate, the next quinate and ſimple, or in an inverted order, the primary ones quite ſimple: all the leaflets are orbiculate, fleſhy, very ſmooth, rugged and netted with veins, acuminate, but not unfrequently blunt and emarginate, two inches wide and a little more in length; the odd leaflet largeſt, at the baſe acuminate, and as it were running down into the petiole; which is flat, thick and almoſt winged: the lateral leaflets ſeſſile, alternate and oppoſite. Racemes in both ſexes ſimilar. According to Linneus it is a native of Sicily.

2. *P. narbonenſis* agrees with the preceding in the manner of flowering, and the ſituation of the buds: but the racemes are larger. Leaflets ovate-oblong, acuminate, narrower, on ſhort petioles but not ſeſſile, with a longitudinal nerve ſometimes making one ſide of the leaf narrower. Foliation as in *P. Terebinthus*. Fruit twice as large as thoſe of *Terebinthus*, ſubovate, reddiſh, the ſkin netted and wrinkled, on one ſide gibbous downwards, or ſometimes from the middle only.

According to Linneus it grows about Montpelier, as well as in Perſia, Meſopotamia and Armenia, where it was found by Rauwolf.]—Mr. Miller ſays it grows in Italy and the South of France, but is ſuppoſed to have been tranſplanted from ſome other country.

3. [*P. vera* has the appearance of the preceding. The flowering and branching buds are in the ſame reſpective ſituation. Racemes leſs compound, and almoſt as in *P. trifolia*, one to four, alternate. The ſcalelets ſeparating the florets are concave, larger and deciduous. Leaflets five at moſt, very ſharp-pointed, not unfrequently obliquely ovate-lanceolate, or wider downwards on one ſide.

According to Linneus, this is a native of Perſia, Arabia, Syria and India. It is frequent about Aleppo, and Rauwolf ſays that there are whole woods of it near Sermin and Baſilo.] Mr. Miller affirms that it grows naturally in Barbary, Spain, Italy and the Levant. [But he confounds the Piſtacia and Turpentine tree. His *Piſtacia Terebinthus* is the former, and his *P. vera* is the latter.—Deſfontaines ſays it is cultivated in the kingdom of Tunis; and that Linneus's *P. trifolia* ſeems to be nothing more than a variety of it.

The Piſtacia tree was cultivated in England in 1570, by Mr. Gray, as appears from Lobel; it flowers here in april and may[b].

4. The ſituation of the buds is ſimilar to that in the three preceding ſpecies. Leaflets ſeven, the middle ones for the moſt part larger, or the odd leaflet and the two inmoſt ſmaller than the four others; each ovate-oblong, by no means acuminate but yet ſtyled, moſt of them alſo are wider on one ſide. Fruit like that of *P. narbonenſis*, but only half or a third of the ſize, not at all wrinkled, and towards the top gibbous on one ſide, (but not downwards, as in *P. narbonenſis*) with the ſtyle, and having ſometimes a concave circle near the baſe[c].

Monſ. Villars deſcribes it as a low ſhrub, but very thick. The wood is odorous and balſamic. The leaves have two pairs of leaflets, terminated by an odd one which is larger; they are firm, and ſhining on the upper ſurface. The flowers form branching catkins at the axils of the leaves, and are reddiſh.

Native of Barbary and the South of Europe. Cultivated in England in 1730. It flowers here in june and july[d].

Cyprus or Chian Turpentine, which this tree furniſhes, is procured by wounding the bark of the trunk in ſeveral places, during the month of july, leaving a ſpace of about three inches between the wounds; from theſe the Turpentine is received on ſtones, upon which it becomes ſo much condenſed by the coldneſs of the night, as to admit of being ſcraped off with a knife, which is always done before ſun-riſe: in order to free

[b] Hort. kew. [c] Gouan illuſtr. [d] Hort. kew.

it from all extraneous admixture, it is again liquified by the ſun's heat, and paſſed through a ſtrainer; it is then fit for uſe. The quantity produced is very inconſiderable; four large trees, ſixty years old, only yielding two pounds nine ounces and ſix drams; but in the eaſtern part of Cyprus and Chio the trees afford ſomewhat more, though ſtill ſo little as to render it very coſtly, and on this account it is commonly adulterated, eſpecially with other turpentines. The beſt Chio Turpentine is generally about the conſiſtence of thick honey, very tenacious, clear and almoſt tranſparent, white inclining to yellow and of a fragrant ſmell, moderately warm to the taſte, but free from acrimony and bitterneſs. For the medicinal qualities of Turpentine, ſee *Pinus Larix*[r].

5. This is a large tree, with a thick wide roundiſh head. Bark on the ſmall branches gray. Leaflets ſeven or nine, very ſmooth, quite entire, waved and ſubrepand on the edge, bluntiſh. Petiole compreſſed above, ſurrounded here and there with a very ſhort wing. Male flowers terminating, in thyrſoid racemes; with a ſmall, ovate, deciduous, ſilky ſcale, excavated above, at the baſe of each branchlet. Calyx three or five-parted; the ſegments awl-ſhaped and pubeſcent. Stamens five, but ſometimes though ſeldom ſeven; filaments very ſhort; anthers oblong, two-lobed, blunt, deep red, with the pollen yellow. Females in looſe panicled racemes. Scales narrower than in the males. Calyx three or five-parted, with acute ſegments. Styles purple, often unequal. Germ very ſmall, ovoid. Drupe ſomewhat fleſhy, roundiſh, nearly the ſize of a pea, when ripe blueiſh; containing a roundiſh nucleus. In younger trees the leaves are ſometimes elliptic.

Native of Barbary: very common in ſandy uncultivated fields near Coſſa, where many being in rows, it is plain, that this tree was once cultivated there. At the foot of the mountains near Mayane, Tlemſen, &c.

From the bark of the trunk and branches flows at different ſeaſons of the year, but eſpecially in ſummer, a reſinous juice, hardening in the air, of a pale yellow colour, of an aromatic ſmell and taſte that is not unpleaſant, ſcarcely to be diſtinguiſhed from oriental Maſtick, and known by the ſame name *Houle* among the Moors. It is inſpiſſated into lamellæ round the branchlets, or into irregular globules, differing in thickneſs and ſhape, frequently as big as the end of the finger or thumb, ſome of which drop from the tree and are found ſcattered on the ground. The Arabs collect this ſubſtance in autumn and winter, and make the ſame uſe of it as of the Maſtick from Scio; chewing it to give a pleaſant ſmell to the mouth, and brightneſs to the teeth.

At the foot of mount Atlas this tree is larger than any other which grows there, but the reſinous juice is ſofter, and of a much leſs pleaſant ſmell and taſte, than that which flows from the trees of the deſert, which is probably occaſioned by the climate being cooler, and the ſoil more moiſt and fertile. The leaves have frequently thick round red galls on them, reſembling berries. The Moors eat the drupes; and bruiſe them to mix with their dates[s].]

6. The Lentiſcus or common Maſtick tree riſes to the height of eighteen or twenty feet, the trunk being covered with a gray bark. It ſends out many branches, which have a reddiſh-brown bark. The leaves have three or four pairs of ſmall leaflets, of a lucid green on their upper, but pale on their under ſide: the midrib has two narrow borders or wings running from one leaflet to another. The male flowers come out in looſe cluſters from the ſides of the branches, are of an herbaceous colour, appear in may, and ſoon fall off: they are generally on different plants from the fruits, which alſo grow in cluſters, and are ſmall berries, of a black colour when ripe.

[Fabricius remarks, that the male plant in time produces hermaphrodite flowers with three ſtamens and five ſtyles, which are followed by fruit.

It is obſerved by Gouan that the buds are different from thoſe of the other ſorts; the branch-bearing buds being terminating; the flowering-buds in both ſexes axillary and in pairs: hence the aments are alſo in pairs, cloſe, almoſt united at the baſe, and equal: the female aments are longer and narrower, the males thicker and ſhorter. The leaves have five leaflets on each ſide, which are nearly equal but variable; ſome being lanceolate, or oblique, ſo that one ſide is gibbous downwards, the other upwards, ſome emarginate, and moſt frequently alternate. The petioles are ſo much winged, that the leaves may be called articulately pinnate. There is frequently a thread between the outer leaflets.

Deſfontaines deſcribes the trunk as covered with a wrinkled and tubercled bark; the branches as numerous, twiſted, and forming a roundiſh head: the leaves as perennial; the petiole channelled and compreſſed above; the leaflets ſmooth, oppoſite or alternate, even, rigid, paler underneath, attenuated at the baſe, quite entire, obtuſe or acute, mucronate. Male flowers ſmall, crowded, ſeſſile, racemed, axillary. Filaments longer than the calyx; anthers purple, two-lobed, two-celled. Female flowers axillary, racemed; racemelets a little longer and looſer. Berry roundiſh, at firſt red, but when ripe browniſh.

Lentiſcus or Maſtick tree is a native of the South of Europe, and the Levant. Deſfontaines informs us that it is very common in Barbary both wild on the hills and cultivated in gardens; but that it is little if at all reſinous, though the branches and bark of the trunk were wounded at different ſeaſons of the year; that the wood however yields an aromatic ſmell in burning; and that the berries yield an oil fit both for the lamp and the table.

In the iſland of Chio the officinal Maſtick is obtained moſt abundantly, by making tranſverſe inciſions in the bark of the tree, whence the Maſtick exudes in drops, which are ſuffered to run down to the ground, and after they are concreted they are collected for uſe. Theſe inciſions are made at the beginning of auguſt, when the weather is very dry, and are continued till the end of ſeptember.

Maſtick is a reſinous ſubſtance, brought to us in ſmall yelloviſh tranſparent brittle grains or tears: it has a light agreeable ſmell, eſpecially when rubbed or heated: on being chewed, it firſt crumbles, ſoon after ſticks together, and becomes ſoft and white, like wax, without impreſſing any conſiderable taſte. It totally diſſolves, except the earthy impurities, which are commonly in no great quantity, in rectified ſpirit of wine, and then diſcovers a degree of warmth and bitterneſs, and a ſtronger ſmell than that of the reſin in ſubſtance. Boiled in water, it impregnates the liquor with its ſmell, but gives out little or nothing of its ſubſtance; diſtilled with water, it yields a ſmall quantity of a limpid eſſential oil, in ſmell very fragrant, in taſte moderately pungent. Rectified ſpirit brings over alſo in diſtillation the more volatile odorous matter of the Maſtick.

It is a common practice with the Turkiſh women to chew this reſin, eſpecially in the morning, not only to render their breath more agreeable, but to whiten the teeth, and ſtrengthen the gums; they alſo mix it with their fragrant waters, and burn it with other odoriferous ſubſtances in the way of fumigation. It is uſed in Europe by japanners, in ſome of their varniſhes.

As a medicine, Maſtick is conſidered to be a mild corroborant and aſtringent; and as poſſeſſing a balſamic power, it has been recommended in hæmoptyſis, proceeding from ulceration, fluor albus, debility of the ſtomach, and in diarrhœas and internal ulcers. Chewing this drug has likewiſe been ſaid to be of uſe in pains of the teeth and gums, and in ſome catarrhal complaints; it is now however ſeldom uſed either externally or internally.

The wood of this tree is received into the *Materia Medica* in ſome foreign Pharmacopœias, and is highly extolled in dyſpeptic, gouty, hæmorrhagic, and dyſenteric affections[t].

It was cultivated here in 1664; as appears in Evelyn's kalendar; and flowers in may[u]. The only

[r] Woodville. [s] Deſfontaines. [t] Woodville. [u] Hort. kew.

tree

tree which Dr. Woodville obſerved to flower in England, was a male plant in the Apothecaries Garden at Cheliſea.]

β. This riſes to the ſame height as the preceding; but differs from it in having a pair or two of leaflets more to each leaf, much narrower and of a paler colour. [Gouan ſays it differs from the common Maſtick only in having the leaflets ſmaller by half, five or ſeven on each ſide, ſharper, more alternate, and the petioles more concave above.]

Native of the country about Marſeilles and ſome other places in the South of France.

PROPAGATION AND CULTURE.

The Piſtacia-nut tree is propaged by the nuts, obtained from abroad, planted in pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed: when the plants appear, admit a large ſhare of air to them, to prevent their drawing up weak; and by degrees harden them to bear the open air, to which expoſe them the beginning of June till autumn, when they ſhould be placed under a hot-bed frame to ſcreen them from the froſt in winter; for while they are young, they are too tender to live through the winter in England without protection, but they ſhould always be expoſed to the air in mild weather; theſe plants ſhed their leaves in autumn, and therefore ſhould not have much wet in winter; and in the ſpring, before the plants begin to ſhoot, they muſt be tranſplanted each into a ſeparate ſmall pot; and if they are plunged into a very moderate hot-bed, it will forward their putting out new roots; but as ſoon as they begin to ſhoot, they muſt be gradually hardened, and placed abroad again; theſe plants may be kept in pots three or four years till they have got ſtrength, during which time they ſhould be ſheltered in winter; and afterwards they may be turned out of the pots, and planted in the full ground, ſome againſt high walls to a warm aſpect, and others in a ſheltered ſituation, where they will bear the cold of our ordinary winters very well, but in ſevere froſts they are often deſtroyed. The trees flower and produce fruit in England, but the ſummers are not warm enough to ripen the nuts.

4. The Turpentine tree may be treated in the ſame manner, and is as hardy. There was a tree of this ſort growing in the garden of the Biſhop of London at Fulham, againſt a wall, which was planted there in Biſhop Compton's time, and endured the winters without cover: and ſome trees of this ſort which were planted in the open air in the garden of his Grace the Duke of Richmond, at Goodwood in Suſſex, ſurvived ſeveral winters without any protection.

6. The plants of this ſort are generally propagated by laying down their young branches, which, if properly managed, will put out roots in one year, and may then be cut off from the old plants, and each tranſplanted into ſeparate ſmall pots. Theſe muſt be ſheltered in winter, and in ſummer placed abroad in a ſheltered ſituation, and treated in the ſame way as other hardy kinds of green-houſe plants. It may alſo be propagated by ſeeds in the ſame way as the others; but if the ſeeds are not taken from trees growing in the neighbourhood of the male, they will not grow; and if they are kept out of the ground till ſpring, the plants rarely appear till the ſpring following. When theſe plants have obtained ſtrength, ſome of them may be turned out of the pots, and planted againſt warm walls; where, if their branches are trained againſt the walls, they will endure the ordinary winters very well, and with a little ſhelter in ſevere winters they may be preſerved.

DESCRIPTION, *&c.*

This is a ſtemleſs, floating, elegant plant. Roots many, a foot and half long, put forth ſimple fibres from their circumference, an inch and half in length, numerous, not ill repreſenting the leaves of Ranunculus aquaticus. Other capillary fibres, ſhorter and in cluſters, come out at the baſe of the leaves and the origin of the principal roots. Leaves various in number and ſize according to the age of the plant, whilſt the plant is in vigour about twenty, ſpread out in a circle or like a roſe, a foot in diameter. They are obovate, attenuated at the baſe, for the moſt part quite entire, ſometimes emarginate, ſeſſile, patulous, lanuginoſe at the baſe, between the nerves and on the upper ſurface villoſe, thick, ſpongy, a little ſucculent, and therefore well adapted for floating; but on the back, from a thicker very large and ſubovate area they puſh forth aſcending, very thick, and extremely prominent nerves. According to Swartz, the leaves are ſubſeſſile, wedge-ſhaped at the baſe, elliptic, radiate-veined, glaucous-velvety on the upper ſurface: the central leaves are ſmaller than the outer ones; the inmoſt erect, convoluted, tomentoſe. Runners are produced from the root under the leaves; they are long, and terminated by other ſmaller plants. The corolla of Jacquin is called by him a ſpathe.—Flowers whitiſh, inodorous, axillary, ſolitary and erect, on a ſhort pedunclc. The corolla ſhrivels up more or leſs, and burſts as the germ increaſes.

Adanſon in his hiſtory of Senegal affirms, that the primary root is fixed ſtrongly into the bank. Jacquin did not attend to this circumſtance, but remarks, that in taking the plants out of the water, he never found

any

any reſiſtance: he ſuggeſts however that the young plants may be fixed at firſt, and afterwards break looſe*.

Native of Aſia, Africa, South America, and the Weſt Indian iſlands, in ſtagnant waters and quiet ſtreams; flowering in april.]

DESCRIPTIONS, *&c.*

1. [Root annual, ſlender, fibrous. Stems hollow whilſt young, brittle, branched, ſmooth, weak, climbing by terminating tendrils. Leaves abruptly pinnate, compoſed uſually of two pairs of leaflets, which are oval and ſmooth. Stipules large, ſurrounding the ſtem or branch. Flowers lateral, two or three together on long peduncles. Corolla white, greeniſh white, purple or variegated. Legumes commonly in pairs, about two inches long, of an oblong form, ſmooth, ſwelling at the ſtraight future, where the ſeeds are faſtened, flatted next the other future, which arches eſpecially towards the end. Seeds from five or ſix to eight or nine, commonly globular, but in ſome varieties irregular or approaching to a cubic form, ſmooth, white, yellow, blue, gray, brown or greeniſh, with a ſmall oblong umbilicus. The colour of the whole plant is glaucous, or hoary green, from a white meal which covers it. Linneus remarks that the leaflets are conduplicate or doubled together.

It is ſaid to be a native of the South of Europe. Loureiro informs us that it is found in China and Cochinchina, but that it is not frequent, and perhaps not indigenous. According to Thunberg, it is cultivated in moſt provinces of Japan.

Like other favoured plants, this has many varieties. The principal ones are given above.

Ray has ſixteen.

* Jacquin.

The varieties enumerated by Parkinſon, in his *Paradiſus*, 1629, are

1. The Rouncivall.
2. The green Haſting.
3. The Sugar Peaſe.
4. The Spotted Peaſe.
5. The Gray Peaſe.
6. The white Haſting.
7. The Peaſe without Skins.
8. The Scottiſh or Tufted Peaſe, which ſome call the Roſe Peaſe.
9. The Early or French Peaſe, which ſome call Fulham Peaſe, becauſe the grounds thereabouts bring them ſooneſt forward for any quantity, although ſometimes they miſcarry by their haſte and earlineſs.]

Out of the great variety of Garden Peas cultivated in England, Mr. Miller mentions only thoſe which are commonly known, placing them according to the time in which they are gathered for the table:

1. The Golden Hotſpur.	10. Sugar Dwarf.
2. The Charlton.	11. Sickle Pea.
3. The Reading Hotſpur.	12. Marrowfat.
4. Maſters's Hotſpur.	13. Dwarf Marrowfat.
5. Eſſex Hotſpur.	14. Roſe, or Crown Pea.
6. The Dwarf Pea.	15. Rouncival Pea.
7. The Sugar Pea.	16. Gray Pea.
8. Spaniſh Morotto.	17. Pig Pea.
9. Nonpareil.	

[The *Hotſpurs* and *Haſtings* have their names from their coming to bear early in the ſeaſon. The ſix firſt varieties are of this nature, and being low growers, require ſticks of three or four feet only in height; and the Dwarf Pea not ſo much. New varieties of theſe are raiſed almoſt every year, which becauſe they differ in ſome ſlight particular, are ſold at an advanced price, and have frequently the names of the perſons who raiſed them, or the place where they firſt grew. Theſe varieties are not permanent, and without the greateſt care will ſoon degenerate. Beſides the above, we have the *early* Charlton Hotſpur, the *early* Golden Hotſpur, *Nicholas's earlieſt* Hotſpur, &c. &c.

Of the larger Peas (7 to 13 and 15) there are alſo ſeveral varieties; as the large and Dwarf Marrowfat; the large and Dwarf Sugar Pea; the Green, and White Rouncival Pea, &c. They all grow tall, and require ſticks from five or ſix to ſeven or eight feet in height.

Beſides the common Roſe or Crown Pea, there is a variegated one—the Egg Pea—the Cluſter Pea—the large Gray Pea—the crooked Gray Pea, and innumerable others of thoſe which are uſed in Field culture.

Dr. Plott enumerated ſome of theſe in 1683. Henley Gray. Blue. Sandwich. Hampſhire Kids. Horn Gray. Early White. Latter White. Blue and Green. Bowdies. Red-ſhanks, Cotſwould. Partridge. Black-eyed Whites. Small Rath-ripe. Roſe. Horn. Large Huſcods.—Theſe have had their day, and others have ſucceeded, to yield again to others.]

Mr. Miller has a perennial Pea, which he calls *Piſum americanum* or *Cape Horn Pea*, from its having been brought by Lord Anſon's cook, when he paſſed that Cape, where this Pea was a great relief to the ſailors; but it is not ſo good for eating as the worſt ſort cultivated in England. It is a low trailing plant; there are two leaflets on each foot-ſtalk, thoſe below ſpear-ſhaped and ſharply indented on their edges; but the upper ones ſmall and arrow-pointed. The flowers are blue, each peduncle ſuſtaining four or five of them. Legumes taper, near three inches long. Seeds round, about the ſize of Tares.

2. [Sea Pea has a perennial root, running far and deep among the ſtones or into the ſand in every direction. Stems procumbent, quadrangular, a little compreſſed, ſtriated, ſmooth, leafy, many-flowered, glaucous, often reddiſh. Leaves alternate, alternately and abruptly pinnate, ſpreading. Leaflets ſeſſile, oval, obtuſe with a little point, entire, ſmooth, many-veined, glaucous: common footſtalk flattiſh, ſtriated, ending in a branched thread-ſhaped ſmooth tendril. Stipules two together, equal, acute, toothed at the baſe, of the texture and colour of the leaflets, but ſmaller. Cluſters of flowers axillary, ſolitary, as long as the leaves, erect, many-flowered. Common peduncle round, ſtriated, ſmooth; pedicels alternate, ſhort, ſingle-flowered. Flowers rather large, a little drooping: corolla beautifully variegated with red and purple: ſtandard obovate, notched, purple, with a red ridge and veins; wings and keel paler, blueiſh. Germ nearly cylindrical: ſtyle bluntiſh, uniform and not broader in the upper part: ſtigma reaching from its middle to the top on the fore part. Pod oblong, compreſſed, ſmooth, ſtraight on the upper ſide, keeled below, terminated by the permanent ſtyle. Seeds ſeveral[4].

According to Mr. Woodward, the ſtems are ſlightly pubeſcent and ſhort. Leaves numerous: leaf-ſtalks angular, pubeſcent: leaflets alternate, on the lower leaves five or ſeven, upwards nine or eleven; there being always one more on the lower than on the upper ſide of the leaf-ſtalk, which is terminated by a tendril, ſometimes ſimple, but often[er] bifid at the extremity. Stipules oval-lanceolate, broad, arrow-ſhaped at the baſe. Flowers crowded on the ſummit of the naked peduncle. Pods long and narrow. Linnæus (fl. ſuec.) obſerves that the exterior leaflets are ſmalleſt: this does not ſeem to be by any means conſtant, though it is ſometimes ſo. The figure in Flora Danica is bad. Muntingius's is very good. Moriſon's is moderate[5].

It is well remarked by Dr. Smith, that this ſpecies is almoſt as nearly allied to Lathyrus as to Piſum, both in habit and generic character; and that Piſum ſativum is not more different in external appearance from the genus of Lathyrus, than Vicia Faba or the Bean is from the other Viciæ. Theſe however, he adds, are matters of opinion; and in ſo natural a claſs, it is very difficult to find out certain and obvious marks of diſtinction[6].

Sea Pea is a native of the ſea ſhore, among ſtones or in ſand in different parts of Europe, as Sweden, Denmark, England; in great plenty on the ſtony beach, between Orford and Aldborough in Suffolk; near Haſtings, Rye, and Pevenſey in Suſſex; near Lyd in Kent; Guildford over againſt the Comber, and Ingolne mills in Lincolnſhire; on the ſharp ridge running from Portland iſland to Bridport, to the right of the ferry, among looſe pebbles, fifteen or twenty feet above high water mark, but the cows eat it down ſo that it is difficult to procure a ſpecimen in flower. It is found in Canada, quite ſmooth, and of double the ſize. Thunberg alſo ſays it grows in Japan, in the iſland of Nipon, by way ſides, flowering in march, april and may. With us it flowers in july and auguſt.

We learn from the epiſtles of the learned Caius that the Sea Pea was firſt obſerved in the year 1555, when in a great ſcarcity, the poor people on the coaſt of Suffolk about Orford and Aldborough ſupported themſelves with it for ſome time. This ſtory is retailed by Stow and Camden; with the addition, that they were ſuppoſed to ſpring up opportunely in that year of dearth, from a ſhipwrecked veſſel loaded with Peas; whereas the Sea Pea differs from all the varieties of the garden or field Pea, in the length and continuance of its roots, the ſmallneſs and bitterneſs of its ſeed, and in the whole habit and appearance of the plant. It had probably grown a long time on Orford beach unobſerved, till extreme want called it into public notice: the ſeed is ſo bitter, that it would not be eaten, except in a want of better food, and it is certainly not uſed at preſent, though it might be gathered in ſufficient quantity; nay it is neglected by the very birds[7]. The legend of the miraculous arrival of theſe Peas in a time of extreme ſcarcity, is ſtill believed among the country people.]

3. Root annual. Stalk angular, near three feet high. Leaves on winged foot-ſtalks, each ſuſtaining two oblong leaflets. Flowers pale yellow, ſmall. Pods two inches long; containing five or ſix roundiſh ſeeds, a little compreſſed on their ſides; theſe may be eaten green, but unleſs they are gathered very young

they

they are coarſe, and at beſt not ſo good as the common Pea.

[Native of the South of Europe and the Levant. Ray obſerved it among the corn near Leghorn in Italy.—Johnſon the editor of Gerarde's herball (1633) ſays, it is found with us only in gardens. It flowers in june and july.]

PROPAGATION AND CULTURE.

Culture in Hotbeds.

It is a common practice with the gardeners near London, to raiſe Peas upon hot-beds, to have them very early in the ſpring; in order to which, they ſow their Peas upon warm borders under walls or hedges, about the middle of October; and when the plants come up, they draw the earth up gently to their ſtems with a hoe, the better to protect them from froſt. In theſe places they let them remain till the latter end of january, or the beginning of february, if they are preſerved from froſts, obſerving to earth them up from time to time as the plants advance in height, as alſo to cover them in very hard froſt with Peas-haulm, ſtraw, or ſome other light covering, to preſerve them from being deſtroyed; then, at the time before-mentioned, they make a hot-bed (in proportion to the quantity of Peas intended) which muſt be made of good hot dung, well prepared and properly mixed together, that the heat may not be too great. The dung ſhould be laid about three feet thick, or ſomewhat more, according as the beds are made earlier or later in the ſeaſon; when the dung is equally levelled, then the earth (which ſhould be light and freſh, but not over rich) muſt be laid on about ſix or eight inches thick, laying it equally all over the bed. This being done, the frames (which ſhould be two or two and a half feet high on the back ſide, and about eighteen inches in front) muſt be put on, and covered with glaſſes: after which it ſhould remain three or four days, to let the ſteam of the bed paſs off, before you put the plants therein, obſerving every day to raiſe the glaſſes to give vent for the riſing ſteam to paſs off; then when you find the bed of a moderate temperature for heat, you ſhould, with a trowel, or ſome other inſtrument, take up the plants as carefully as poſſible, to preſerve the earth to the roots, and plant them into the hot-bed in rows about two feet aſunder; and the plants ſhould be ſet about an inch diſtant from each other in the rows, obſerving to water and ſhade them until they have taken root; after which you muſt be careful to give them air at all times when the ſeaſon is favourable, otherwiſe they will draw up very weak, and be ſubject to grow mouldy and decay. You ſhould alſo draw the earth up to the ſhanks of the plants as they advance in height, and keep them always clear from weeds. The water they ſhould have muſt be given them ſparingly, for if they are too much watered it will cauſe them to grow too rank, and ſometimes rot off the plants at their ſhanks juſt above ground. When the ſun ſhines hot, cover the glaſſes with mats, otherwiſe their leaves will flag, and their bloſſoms fall off without producing pods; as will alſo keeping the glaſſes too cloſe at that ſeaſon. But when the plants begin to fruit, they ſhould be watered oftener, and in greater plenty than before; for by that time the plants will have nearly done growing, and the often refreſhing them will occaſion their producing a greater plenty of fruit.

The ſort of Pea which is generally uſed for this purpoſe is the Dwarf, for all the other ſorts ramble too much to be kept in frames; the reaſon for ſowing them in the common ground, and afterwards tranſplanting them on a hot-bed, is alſo to check their growth, and cauſe them to bear in leſs compaſs; for if the ſeeds were ſown upon a hot-bed, and the plants continued thereon, they would produce ſuch luxuriant plants as are not to be contained in the frames, and would bear but little fruit.

Culture of Peas in the open air.

The next ſort of Pea which is ſown to ſucceed thoſe on the hot-bed is the Hotſpur, of which there are reckoned three or four ſorts; as the Golden Hotſpur, the Charlton Hotſpur, the Maſters's Hotſpur, the Reading Hotſpur, and ſome others, which are very little differing from each other, except in their early bearing, for which the Golden and Charlton Hotſpurs are chiefly preferred; though if either of theſe ſorts are cultivated in the ſame place for three or four years, they are apt to degenerate and be later in ſpring-fruiting, for which reaſon moſt curious perſons procure their ſeeds annually from ſome diſtant place; and in the choice of theſe ſeeds, if they could be obtained from a colder ſituation and a poorer ſoil, than that in which they are to be ſown, it will be much better than on the contrary, and they will come earlier in the ſpring. Theſe muſt alſo be ſown on warm borders, towards the latter end of october; and when the plants are come up, you ſhould draw the earth up to their ſhanks in the manner before directed; which ſhould be repeated as the plants advance in height (always obſerving to do it when the ground is dry) which will greatly protect the ſtems of the plants againſt froſt; and if the winter ſhould prove very ſevere, it will be of great ſervice to the plants to cover them with Peas-haulm, or ſome other light covering; which ſhould be conſtantly taken off in mild weather, and only ſuffered to remain on during the continuance of the froſt; for if they are kept too cloſe, they will be drawn very weak and tender, and thereby be liable to be deſtroyed with the leaſt inclemency of the ſeaſon.

In the ſpring you muſt carefully clear them from weeds, and draw ſome freſh earth up to their ſtems; but do not raiſe it too high to the plants, leſt by burying their leaves you ſhould rot their ſtems, as is ſometimes the caſe, eſpecially in wet ſeaſons. You ſhould alſo obſerve to keep them clear from vermin, which, if permitted to remain amongſt the plants, will increaſe ſo plentifully as to devour the greateſt part of them. The chief of the vermin which infeſt Peas are the ſlugs, which lie all the day in the ſmall hollows of the earth, near the ſtems of the plants, and in the night time come out, and make terrible deſtruction of the Peas; and theſe chiefly abound in wet ſoils, or where a garden is neglected, and over-run with weeds; therefore you ſhould make the ground clear every way round the Peas to deſtroy their harbours, and afterwards in a fine mild morning very early, when theſe vermin are got abroad from their holes, you ſhould ſlack a quantity of lime, which ſhould be ſown hot over the ground pretty thick, which will deſtroy the vermin wherever it happens to fall upon them, but will do very little injury to the Peas, provided it be not ſcattered too thick upon them. This is the beſt method I could ever find to deſtroy theſe troubleſome vermin.

If this crop of Peas ſucceeds, it will immediately follow thoſe on the hot-bed; but for fear this ſhould miſcarry, it will be proper to ſow two more crops at about a fortnight's diſtance from each other, ſo that there may be the more chances to ſucceed. This will be ſufficient until the ſpring of the year, when you may ſow three more crops of theſe Peas; one toward the beginning of january, the other a fortnight after, and the third at the end of january. Theſe two late ſowings will be ſufficient to continue the early ſort of Peas through the firſt ſeaſon, and after this it will be proper to have ſome of the large ſort of Peas to ſucceed them for the uſe of the family; in order to which, you ſhould ſow ſome of the Spaniſh Morotto, which is a great bearer, and a hardy ſort of Pea, about the middle of february, upon a clear open ſpot of ground. Theſe muſt be ſown in rows about three feet aſunder, and the Peas ſhould be dropped in the drills about an inch diſtance, covering them about two inches deep with earth, being very careful that none of them lie uncovered, which will draw the mice, pigeons, or rooks, to attack the whole ſpot; and it often happens by this neglect, that a whole plantation is devoured by theſe creatures; whereas, when there are none of the Peas left in ſight, they do not ſo eaſily find them out.

About a fortnight after this you ſhould ſow another ſpot, either of this ſort, or any other large ſort of Pea, to ſucceed thoſe, and then continue to repeat

ſowing

ſowing once a fortnight, till the middle or latter end of may, ſome of theſe kinds, only obſerving to allow the Marrowfats, and other very large ſorts of Peas, at leaſt three feet and a half, or four feet between row and row; and the Roſe Pea ſhould be allowed at leaſt eight or ten inches diſtance from plant to plant in the rows, for theſe grow very large; and if they have not room allowed them, they will ſpoil each other by drawing up very tall, and will produce no fruit.

When theſe plants come up, the earth ſhould be drawn up to their ſhanks (as was before directed) and the ground kept entirely clear from weeds; and when the plants are grown eight or ten inches high, you ſhould ſtick ſome rough boughs, or bruſhwood, into the ground cloſe to the Peas, for them to ramp upon, which will ſupport them from trailing upon the ground, which is very apt to rot the large-growing ſorts of Peas, eſpecially in wet ſeaſons; beſides, by thus ſupporting them, the air can freely paſs between them, which will preſerve the bloſſoms from falling off before their time, and occaſion them to bear much better than if permitted to lie upon the ground, and there will be room to paſs between the rows to gather the Peas when they are ripe.

The dwarf ſorts of Peas may be ſown much cloſer together than thoſe before-mentioned, for theſe ſeldom riſe above a foot high, and rarely ſpread above half a foot in width, ſo that theſe need not have more room than two feet row from row, and not above an inch aſunder in the rows. Theſe produce a good quantity of Peas, provided the ſeaſon is not over dry, but they ſeldom continue long in bearing, ſo that they are not ſo proper to ſow for the main crop, when a quantity of Peas is expected for the table, their chief excellency being for hot-beds, where they will produce a greater quantity of Peas, provided they are well managed, than if expoſed to the open air, where the heat of the ſun ſoon dries them up.

The Sickle Pea is much more common in Holland than in England, it being the ſort moſtly cultivated in that country; but in England they are only propagated by curious gentlemen for their own table, and are rarely brought into the markets. This ſort the birds are very fond of, and if they are not prevented, many times deſtroy the whole crop. This ſhould be planted in rows about two feet and a half aſunder, and ſhould be managed as has been directed for the other ſorts. Although I have directed the ſowing of the large ſorts of Peas for the great crop, yet theſe are not ſo ſweet as the early Hotſpur Peas; therefore it will alſo be proper to continue a ſucceſſion of thoſe ſorts through the ſeaſon, in ſmall quantities, to ſupply the beſt table, which may be done by ſowing ſome every week or ten days; but all thoſe which are ſown late in the ſeaſon, ſhould have a ſtrong moiſt ſoil, for in hot light land they will burn up and come to nothing.

The large-growing ſorts may be cultivated for the common uſe of the family, becauſe theſe will produce in greater quantities than the other, and will endure the drought better, but the early kinds are by far the ſweeter taſted Peas.

The beſt of all the large kinds is the Marrowfat, which if gathered young, is a well-taſted Pea, and this will continue good through the month of auguſt if planted on a ſtrong ſoil.

The Field Culture.

The Gray and other large winter Peas are ſeldom cultivated in gardens, becauſe they require a great deal of room, but are uſually ſown in fields in moſt parts of England. The beſt time for ſowing theſe is about the beginning of march, when the weather is pretty dry, for if they are put into the ground in a very wet ſeaſon, they are apt to rot, eſpecially if the ground be cold; theſe ſhould be allowed at leaſt three or four feet diſtance row from row, and muſt be ſown very thin in the rows; for if they are ſown too thick, the haulm will ſpread ſo as to fill the ground, and ramble over each other, which will cauſe the plants to rot, and prevent their bearing.

The common White Pea will do beſt on light ſandy land, or on a rich looſe ſoil. The uſual method of ſowing theſe Peas is with a broad-caſt, and ſo harrow them in; but it is a much better way to ſow them in drills about three feet aſunder; for leſs than half the quantity of ſeed will do for an acre, and the ground may be hoed, both to deſtroy the weeds, and earth up the Peas. The uſual time for ſowing theſe Peas is the middle of march or the beginning of april, on warm land; but on cold ground they ſhould be ſown a fortnight or three weeks later. In the common way of ſowing they allow three buſhels or more to an acre; but if they are drilled, one buſhel and a half will be full enough.

The Green and Maple Rouncivals require a ſtronger ſoil than the white, and ſhould be ſown a little later in the ſpring; the drills alſo ſhould be at a greater diſtance, as two feet and a half or three feet, for this ſort is apt to grow rank, eſpecially in a wet ſeaſon. The ground between the rows ſhould be hoed two or three times.

The Gray Peas thrive beſt on a ſtrong clayey land: theſe are commonly ſown under furrow; but by this method they are always too thick, and do not come up regularly, they therefore ſhould alſo be ſown in drills. Being much hardier than the former ſorts, theſe may be ſown towards the end of february.

The beſt method to ſow theſe Peas is to draw a drill with a hoe by a line two inches deep, and having ſcattered the ſeeds in it, to draw the earth over them with a rake. This is a quick method for gardens; but where they are ſown in fields, they commonly make a ſhallow furrow with the plough, and harrow in the ſeeds. Where labour is dear, it is a great expenſe to weed and earth up the plants by hand-hoeing; but it may be eaſily effected by a horſe-hoe, which will not only kill the weeds, but by ſtirring the ſoil render it mellow, greatly promote the growth of the plants, and render the ground fitter to receive another crop the following ſeaſon.

Saving Seed.

When any ſorts are intended for ſeed, there ſhould be as many rows left ungathered, as may be thought neceſſary to furniſh a ſufficient quantity; and when the Peas are in flower, they ſhould be carefully looked over, to draw out all the plants which are not of the right ſort; for there will always be ſome roguiſh plants, as the gardeners term them, which, if left, will cauſe the others to degenerate. The reſt muſt remain until their pods are changed brown and begin to ſplit; when the plants ſhould be pulled up, and ſtacked till winter, or elſe threſhed out as ſoon as they are dry, and put up in ſacks. Let them not remain too long abroad after they are ripe, for wet will rot them; and heat after rain will cauſe the pods to burſt and throw out the ſeeds.

By diligently drawing out bad plants, and marking thoſe which come earlieſt to flower, the gardeners have greatly improved their Peas of late years, and are conſtantly endeavouring to get forwarder varieties.

As it is ſcarcely an object with gentlemen to ſave their own ſeed, except in the caſe of having a particular ſort which they cannot purchaſe; ſo it is not adviſable to continue ſowing the ſame ſeed longer than two years on the ſame ground.

[Peas on Hotbeds.

Sow under a ſouth wall about the 24th of ſeptember; put them very near the wall, and when they peep out of the ground, cover them with earth as they advance, about an inch thick: in froſt protect them with peas-haulm, wheat-ſtraw, or dry fern. About the end of january, if the winter has been mild, the Peas will be ſome inches above ground: then make a hot-bed in the manner directed for Cucumbers, except that the dung may be only two feet thick.

Make the hot-bed four feet broad, level the dung well, and cover it with ten inches of light virgin earth. The frames ſhould be two feet high in the back, ſloping to fifteen inches in front. Having put theſe on the hot-bed, in the day time tilt up the glaſſes, that the ſteam may paſs off. When the bed is become of a moderate temperature, take up the Peas with a ball of earth to their roots, and plant them

fourteen inches row from row, and four inches plant from plant. Water them moderately at planting, but afterwards ſparingly, for much water makes them grow to ſtraw, and produce little fruit. Shade the beds from eleven until the ſun is near off, and at the ſame time give them air in mild weather. Cover the dung which ſurrounds the frames with earth, that when the glaſſes are tilted up to give air, the Peas may not be blighted with the rancid ſteam of the dung.

Dwarf Peas, and ſome of the early Hotſpurs may alſo be ſown in pots in ſeptember, ſinking the pots in the common earth; and when froſt ſets ſtrong in, the pots may be ſet under cover, in a green-houſe or glaſs-caſe. Make a border in front of the green-houſe of good freſh earth; and about the beginning of december take the Peas out of the pots, and plant them in the border in rows at three feet diſtance, and ten inches aſunder in the rows, watering them gently. Give them air, and draw the earth up to their roots. When they are in bloom give them a good portion of water, which has ſtood in the houſe twenty-four hours. A crop of Peas may be thus obtained about the middle of march.

Peas in the open ground.

It is better to ſow two rows of Peas cloſe together, that is, within ten inches or a foot of each other, leaving between each pair of thoſe cloſe rows an interſtice of two feet for the dwarf Peas, of three feet for the early climbers, and three feet and a half or four feet for the larger ſorts. The reaſon of this is, that the ſtakes or buſhes being placed between two cloſe rows will ſupport both, whereas in the common way of ſowing Peas, every row muſt have a row of buſhes. Gardeners who vie with one another for the earlieſt Peas, never ſtake them, alledging that it gives them liberty to grow too much to haulm, and that the early fruit will thereby be prevented from ripening ſo ſoon. This may be the caſe in ſandy ſoils; but in ſtronger lands, if the Peas, eſpecially the larger ſorts, are not ſupported, they will infallibly rot, before they can be fit for the table[b].

Field Culture of Peas.

Peas are cultivated by the farmer either alone or with Beans. In ſtrong lands the Bean is the predominant crop, in lighter lands the Pea. In ſuch lands the Pea is more frequently ſowed alone. The ſorts commonly ſowed in fields are the Gray, the Blue, and the White. Of theſe there are innumerable tranſient varities in our different counties. In Suſſolk, where the culture of the Pea is well underſtood, they reckon 1. The common White. 2. The Forty-day. 3. The Charlton. 4. The Blue. 5. The large Gray. 6. The ſmall Gray. 7. The Speckled. 8. The large Dutch. 9. The Dun.

Time of ſowing.

The Gray Peas will bear being ſown in autumn, and it is a common practice in Hertfordſhire to begin Pea-ſowing as ſoon as the Wheat-ſeed is over. The Peas which are ſown in autumn or before Chriſtmas are late ſorts, and therefore are not proper where the crop is to be harveſted time enough for Turneps.

The Forty-day, or the Charlton Pea, ſhould be ſown early in march, and if Turneps are intended, not later than that month: late ſown crops are ſubject to the green fly or dolphin; and to avoid that it is recommended to ſow in february. If Peas are not intended as a preparation for Turneps, many ſow before Chriſtmas; but this muſt be on dry land, and in a dry time; for if they are ſown after rain or ſnow, the crop will ſuffer.

Tillage.

A common method in Suffolk is to put in Peas on a lay with only one ploughing; the ſeed to be pricked in with iron dibbles. This method ſucceeds greatly: but it ſhould be practiced only on loams and good ſand: very poor ſand will not do for Peas; and on clay Beans anſwer far better.

When the crop is put on a ſtubble, the land ſhould be ploughed in autumn, and, if the ſeaſon requires it, twice in the ſpring; but one ploughing, judiciouſly timed, may do better than two. The ſeed may be either ploughed or harrowed in; if the former, it muſt not be above three inches deep: but harrowing in is ſafer, if the harrows let them in two inches; in this caſe they muſt be watched againſt rooks and pigeons.

Quantity of Seed.

Leſs than three buſhels an acre ought not to be ſown broadcaſt. One great object, perhaps the greateſt in this crop, is to procure a thick cover over the ſoil, to deſtroy weeds, and breed a moiſt fermentation on the ſurface; which can never be effected with a thin crop. If the produce only be regarded, and the hoes are deſigned to be perpetually at work, two buſhels and even leſs are enough.

Two buſhels is the common allowance. Some ſow four buſhels, but that is clearly too much.

Drilling and Dibbling.

When Peas are planted by hand, on a turf ploughed once, it is called dibbling. A man walking backwards, that he may not tread on the holes, ſtrikes a dibble, that makes two holes, ſometimes three, on a nine inch furrow, and is followed by boys, who drop a Pea in every hole. Both theſe operations are in Suffolk done for eight ſhillings an acre. They are covered by a buſh-harrow. The Peas come up about four inches every way; and being ſo cloſe neither want nor admit of hoeing. Seven pecks or two buſhels of ſeed do an acre.

Drilling is uſed on land in tilth. The rows ſhould be double at eighteen inches aſunder, and then an interval of two feet: in the hoeing attention ſhould be given to make the two rows clalp together.

Hoeing and Weeding.

Drilled Peas ſhould be hand-hoed well whilſt the crop is young, and afterwards in the intervals, taking care not to tread on the plants. If weeds get up afterwards, they ought not to be meddled with; for the crop will be pulled about and ſpoiled in getting them out. Even horſe-hoeing ſhould not be ventured after the plants are near maturity. Some hand-hoe once, and horſe-hoe twice or thrice afterwards, as there may be occaſion.

If broadcaſt Peas be hoed, it muſt be whilſt they are very young: when they cling together, more miſchief is done by going among them, than good by the hoe. If the land was in good order, and the ſeed ſown thick enough, they will ſtand in no need of hoeing.

Harveſting.

Peas, when near ripe, are very apt to be devoured by rooks, pigeons, &c. they ſhould therefore be well watched. They are generally cut with a tool called a *peas-make*, which is half an old ſcythe fixed in a handle, with which they are rolled as they are cut into ſmall bundles called *wads*, in other places *wiſps*. Theſe ſhould be ſmall to dry well, and ſhould lie out ſome days to wither. In ſome counties they are reaped with a hook. They are ſometimes mown, but it is a very bad practice.

Preparation for Turnept.

By ſowing the Charlton, or Forty-day Pea early in march, the crop will be cleared in june, or the firſt week in july, which is a good ſeaſon for Turneps, and on all dry ſoils, ought never to be neglected. If the harveſt happens to be later, the wads ſhould be laid in rows, and the ploughs ſent in, by which a week or perhaps ten days may be gained. The advantages of this practice muſt be obvious, when it is conſidered that a thick ſmothering crop of Peas not only chokes weeds, but improves the ſoil, particularly in leaving the ſurface looſe and friable, from the putrefactive fermentation carried on under the crop; by retaining moiſture, and excluding the ſun; and if the land be ploughed directly, which is a great point, though much neglected, proves a fine preparation for Turneps. The Peas are not the only gain, but the ſaving in tillage; for by this means the latter crop is put in upon one ploughing only, which can be effected no other way.

Produce.

Of all crops this is the moſt uncertain, and it is rarely conſiderable, two quarters and a half an acre are about the average produce: now and then four,

[b] Juſtice's Brit. Gard. p. 102 and 195.

four and a half, and five quarters are gained, but probably not one year in ten.

The greateſt burdens of Straw, in crops that perfectly cover the ground, do not yield a very large produce. If a man ſhades his land well, and gets two and a half or three quarters on an acre, he has reaſon to be ſatisfied with the produce.

Application.

The principal application of Peas is for fattening hogs. No other grain agrees better with them, eſpecially when they are harveſted dry and ground into meal.

Bread made of this meal was formerly much in uſe in ſome parts of Scotland, but of late it is ſaid to have been almoſt wholly given up. It is reported to be mixed with wheat flour by the millers, when Peas are reaſonable.

The Straw, if well harveſted, is a very conſiderable object for fodder; it is little inferior to ordinary Hay, and all ſorts of cattle thrive well on it; but it is apt to gripe ſome horſes, if given too ſoon. It ſhould not be uſed before january; and if it is found to have this effect, a few Turneps, Cabbages, Carrots or Potatoes, will correct it[1].

Culture in Kent.

The following varieties are commonly cultivated by Kentiſh farmers, viz. The Reading and Leadman's Dwarfs, for breaking Peas and fattening hogs; the Gray Polt; Nutmeg Gray; Early Dun, in Eaſt Kent called Sutton's Gray; and Shepherd's Gray: all which are for fattening hogs. Beſides theſe, many others are cultivated for ſupplying the London ſeedſmen.

All are drilled in rows, about eighteen inches apart, from the middle of february to the end of march, and ſometimes later. They are hand and horſe-hoed, and are harveſted from the middle of july till the end of ſeptember. They are reaped with a hook, called a podware hook. The produce is from one and a half to five quarters on an acre. Leadman's Dwarf, and the Early Gray are thought to be the moſt prolific. The Early Charlton is frequently off the ground in time to get a good crop of Turneps[2].

Culture in Middleſex.

About three thouſand acres are annually cropped with Peas in this county; they are much on the increaſe, and are cultivated in the moſt clean and garden-like manner.

Preparation, &c.

On upwards of two thouſand acres they ſucceed a clean crop of Beans; in which caſe the Bean ſtubble is ploughed up with a thin furrow about january, and during every dry time till march, and ſoon afterwards re-ploughed a full depth. The water-furrows are kept open, and the land remains in this ſtate till ſeed time.

Peas ſown with an intention of being ſent to market green, ſucceed Clover, Corn or any other crop. In Eſſex they frequently follow Potatoes. As long as the land is cleared and properly prepared, which will generally be accompliſhed by the middle of november, White Hotſpur Peas are planted for podding for the London market.

The land is generally a dry loamy ſand, and manure is conſtantly ploughed in during january and february; after which it is harrowed, and is then fit for the reception of the ſeed, which is put into drills fifteen inches apart, moſtly made acroſs, but occaſionally along the ridges; and the ſeed is covered in with the hoe. Some perſons buſh-harrow the whole. The quantity of ſeed ſown is generally about three buſhels an acre. Such as are intended for podding, are put into the ground every week or fortnight, during the months of january, february and march, for a regular ſucceſſion of crops to ſupply the market daily. Gray Peas are ſown during the whole of march.

Culture.

The intervals between the rows are twice hand-hoed, once when the plants are about three inches high, and again a ſhort time before they are in bloſſom. The rows are laid down and well earthed up by the laſt hoeing, and they are carefully weeded by hand.

Harveſting.

Againſt the podding ſeaſon poor people from every part of London apply to the farmers who have early Peas. Many of the richer ſort ſell their Peas by the acre to perſons who employ the podders, and who gather by the ſack of four buſhels. About forty podders are ſet to ten acres. Carts are loaded and ſent off ſo as to be delivered to the ſaleſmen at market from three to five o'clock in the morning.

In Eſſex they are uſually ſold in the field at 5l. an acre, reſerving the haulm for fodder.

The Peas are uſually picked twice over, after which, if from a ſcarcity of hands any be left for ſeed, it is eſteemed a loſs. When hands are in plenty, the crop is picked clean, the haulm is cut up with hooks, removed on to every fifth ridge, or into a graſs field to dry: it is then put into ſtacks for horſe-feed, and the land is prepared as ſpeedily as poſſible for Turneps. The podders are paid for the Marrowfats and other larger Peas about 1s. and for the ſmaller 16d. or 18d. per ſack. They are ſold in the market at from 5s. to 17s. per ſack: ſo that this crop may be expected to return from leſs than 5l. to upwards of 20l. per acre.

The Gray and other late Peas ſtand to ripen their ſeed; they are then cut up with hooks, rolled into wads, turned once or twice, and then ſtacked up.

Application.

About one-third of the ſeed is eaten by men, and the reſt by hogs. The haulm cut green, and dried quickly whilſt in the full vigour of its ſap is nearly as good as hay for cattle and horſes[1].

2. Sea Pea may be propagated by ſeeds or by the roots. Though a native of the ſea coaſt, it is eaſily cultivated in gardens.]

3. Yellow-flowered Pea may be managed in the ſame way with the Common Pea.

DESCRIPTIONS, &c.

1. This is a tree with proliferous branches, three or four to each whorl, round, with an aſh-coloured bark, from very ſhort ovate imbricate buds. Leaves under each whorl three or four, two inches long, oblong, moſtly obovate, quite blunt and entire, even, pale green, ending at the baſe in a petiole an inch in length. Peduncle from a diſtinct bud, ſolitary, an inch in length, tomentoſe, many-flowered. Flowers on umbelled pedicels, the length of the peduncle, tomentoſe, five, the two middle ones two or five-flowered; the lateral one-flowered. Calyx tomentoſe, five-cleft: ſegments oblong, blunt. Corolla ſmooth, twice as long as the calyx. Petals linear, blunt.
Native of the Canary iſlands[q]. Introduced in 1787, by James Webſter, Eſq. It flowers in may[r].
2. Capſule ſubglobular, dagger-pointed at the top, obſcurely three-cornered, three-celled, three-valved, on the outſide ſomewhat wrinkled, ſmoky; within bay-coloured, and having a yelloviſh reſinous juice. Seeds three or four in each cell, variouſly angular, but commonly like the ſtones of the grape, marked on the back with a ſhallow groove, black, ſhining, anointed with turpentine.
3. Capſule ſubglobular, with two ſwellings, the tranſverſe diameter longeſt, dagger-pointed at top, having a groove on both ſides, and a ridge at both edges, from the prominent ſuture, ſhagreened all over, two-celled, two-valved: cells reſinous. Seeds four in each cell, very irregular, wrinkled, black, ſhining[s].

Stem branched ſhrubby, leaves lanceolate toothed, heads leafleſs.

38. Plantago parviflora. *Small-flowered Plantain.*
Deſfont. atlant. 141.
Leaves oppoſite linear ciliate, peduncles ſhorter than the leaf, heads round, bractes preſſed cloſe equalling the calyx.

DESCRIPTIONS, *&c.*

1. The root of the *Great Plantain* or *Waybread*, when old, is the thickneſs of the thumb, præmorſe or ſtumped, laying ſtrong hold of the earth by its fibres, which ſtrike deeply, and are whitiſh. Leaves petioled, ſeven-ribbed or ſometimes nine-ribbed, ſmooth, but ſomewhat hairy when young, about a hand in length, often remotely toothed about the edge. Petioles long, convex on the under ſide, concave above, each forming a kind of ſheath at its baſe. Scapes upright, pubeſcent, longer than the leaves. Spikes cylindrical, very long, linear, compoſed of many cloſely imbricate flowers, under each of which is a lanceolate concave bracte. Diviſions of the calyx ovate, concave, blunt, ſmooth, nearly equal. Anthers purple, two celled, each cell terminating at bottom in a point. Style villoſe [a].
Capſule ſuperior, covered with the ſhrivelled corolla, papery: partition membranaceous, looſe when ripe: receptacle fleſhy, excavated, faſtened to the partition on each ſide. Seeds few, about nine in each cell, (according to Leers ſix; but Mr. Curtis ſays, he has commonly found about twenty ſmall ones, whereas *P. lanceolata* has only two large ſeeds); they are ſubovate, ſlightly convex on one ſide, angular on the other, with a ventral navel in the middle, of a paliſh brown colour [a].
Native of moſt parts of Europe and Japan, in meadows, gardens, and particularly by way ſides, whence its name of *Way-bread*. It is a perennial plant, and flowers during the whole ſummer.
The ſeeds afford food to many of the ſmall birds. Mr. Curtis ſays that cattle in general appear very readily to eat the leaves. According to the Swediſh experiments, ſheep, goats and ſwine eat it; cows and horſes refuſe it.
The leaves have a weak herbaceous ſmell, and an auſtere, bitteriſh, ſubſaline taſte; their qualities are ſaid to be refrigerant, attenuating, ſubſtyptic and diuretic.
Plantain was formerly reckoned among the moſt efficacious vulnerary herbs; and the common people now apply the leaves to freſh wounds and cutaneous ſores. Inwardly they have been uſed in phthiſical complaints, ſpitting of blood, and in various fluxes, both alvine and hæmorrhagic. The ſeeds however ſeem better adapted to relieve pulmonary diſeaſes than the leaves, being extremely mucilaginous. The roots have alſo been recommended for the cure of tertian intermittents, and from the experience of Bergius, not undeſervedly. An ounce or two of the expreſſed juice, or the like quantity of a ſtrong infuſion, may be given for a doſe; in agues the doſe ſhould be double this quantity, and taken at the commencement of the fit.
Plantain is ſaid to be a cure for the bite of the Rattle-ſnake; but probably with little foundation, although it is one of the principal ingredients in the remedy of the Negro Cæſar, for the diſcovery of which he received a conſiderable reward from the Aſſembly of South Carolina [a].
I have followed the late Dr. Withering in the varieties.
β. Is much ſmaller than the common ſort. Leaves three-nerved. Stalk not more than an inch and half high. Spike ſhorter and having fewer flowers in proportion. About Shirehampton, and King's Weſton, near Briſtol.
γ. Leaves with large teeth towards the baſe. A variety ſcarcely worth notice.
δ. Spike leafy. Flower leaves diſpoſed in a pyramidal form.
ε. The ſpike is abortive or compoſed of leaves, as in the preceding, which differs not from this, except in having the ſpike-leaves imbricate in a pyramid; whereas in the roſe Plantain they are expanded like a roſe; both ſorts of ſpike often ſpring from the ſame root. Roſe Plantain is often cultivated in gardens.

[a] Curtis. [a] Gærtner. [a] Woodville.

ζ. Spike

ζ. Spike abortive leafy, branching into a panicle [p]. Bedingham, near Bungay, in Suffolk.

2. Jacquin, who describes this plant in the Supplement to his Collection, says he is unacquainted with its native country. It is a ſtiff and roughiſh plant, pretty much divided or many headed. It bears the open air in ſummer, but muſt be taken into the greenhouſe in winter. The root is perennial, conſiſting of a heap of thick, branchy, white fibres: the radical leaves are numerous, thick, erect, and either of an ovate or lanceolate form from a channelled foot-ſtalk; obtuſe, more or leſs dentated at the edges, frequently almoſt entire, criſp, bullated, nervous, dark green, and two or three inches long. Scapes ſeveral, round, upright, the length of the leaves. Spikes round, denſe. Calycine leaves roundiſh, gloſſy, green, obtuſe, unequal, fleſhy. Petals white, acute. Seeds ovate, punctated, if viewed with a glaſs blackiſh, and not gloſſy [q].

It is thought to be a native of the South of Europe. Mr. Donn, who cultivated it in the botanic garden at Cambridge, attributes it to Sweden, and aſſigns the year 1790 for its introduction.

3. This ſpecies reſembles *P. major* ſo much, that it might eaſily be taken for the ſame: the ſpike however is longer, the flowers remote, the leaves uſually ſomewhat toothed at the baſe, and the ſcape angular [r].

Native of China and Siberia. Introduced in 1787, by Monſ. Thouin. It flowers in july [s].

4. This is a plant which bears the open air. The root is fuſiform, perennial, and the thickneſs of a finger; producing annually ſeveral leaves with long foot-ſtalks, which are marked in front with a furrow. The leaves are lanceolate, ſomewhat acute, either toothed or entire, marked with from five to eleven nerves, villoſe on both ſides, but moſt ſo on the back; hence they feel ſoft to the touch: they vary much in ſize and breadth, ſo that, excluſive of the foot-ſtalks, a leaf of nine inches ſhall be ſometimes of the breadth of half a foot, and ſometimes only two inches. Scapes round, ſtriated, a little villoſe, and from half a foot to two and a half feet high; bearing a cylindric ſpike, from three to five inches long, and very thickly imbricated through its whole length. Calyx green, equal. Petal pale. Filaments very long and whitiſh; and at length a little purpliſh [t].

Native of Siberia. Cultivated in 1763, by Mr. James Gordon. It flowers in july and auguſt [u].

5. Hoary Plantain has the leaves ſmall and leſs blunt than in the common great Plantain, hoary, commonly five-nerved, lying cloſe to the ground, on very ſhort, dilated petioles. Spike ſhort, cloſe. Filaments longer than in P. major, pale purple: anthers white and more ſhowy. Capſules containing only two ſeeds, as in P. lanceolata [x].

Gærtner deſcribes the capſule as covered by both calyx and corolla, of a cylindric-ovate form, opening tranſverſely a little above the baſe, ſo that the lid forms the greater part of it. Partition ſo very thin as to be almoſt evaneſcent in a ſtate of maturity. Seed in each cell one, of an oblong elliptic form, on one ſide convex and ſmooth, on the other concave, with an umbilical tubercle in the middle, of a yellowiſh horn colour, ſhining and mucilaginous. Albumen hard, pale. Embryo dorſal, erect, ſnow-white. Cotyledons linear-oblong, ſhorter than the radicle. Radicle filiform, curved, inferior. The ſtructure is the ſame in P. lanceolata, virginica, Pſyllium, &c.

Root perennial, large when fully grown, penetrating deep, and having numerous lateral fibres, by which it ſupports itſelf in the moſt ſcorching ſeaſons: it is alſo not deſtroyed by frequent mowing, as moſt lawns and graſs-plats teſtify.

Native of moſt parts of Europe, among graſs, eſpecially in calcareous and gravelly ſoils; flowering during the whole ſummer.

6. In America this unfolds its corolla, and puts forth the ſtamens, which it ſcarcely does in Europe. Scape pubeſcent. Leaves half-three-nerved and pubeſcent. It is an annual plant, native of Virginia [y]. Introduced in 1775, by Monſ. Thouin [z].

7. Root perennial. Leaves a foot or a foot and a half in length, thick, with blunt diſtant teeth, on very long petioles. Scapes two or three feet high, when young rugged, but when old almoſt ſmooth. Spike cylindrical, ſcarcely an inch and half in length, ſmooth [a]; in proportion to the ſize of the plant ſhort, compact and cloſe [b].

Native of Italy and Sileſia. Introduced in 1774, by Joſ. Nich. de Jacquin [c].

8. Root of Ribwort Plantain perennial, when old appearing as if bitten off at the end. Leaves all from the root, truly lanceolate, diſtinguiſhed by five (ſometimes three or ſeven) prominent ribs, pointed, entire, or ſometimes having a few teeth near the baſe. Dr. Withering remarks, that in maritime ſituations they are toothed all along the edges. They are of a dark green, moſt hairy beneath, taper at the baſe into a long flat footſtalk, ribbed like the leaf itſelf, and at their inſertion are inveſted with long white woolly hair ſpringing from the crown of the root. Scapes or flowering-ſtalks upright, longer than the leaves, from among which they ſpring; they are clothed at the baſe with the ſame kind of hair, and upwards are ſmoothiſh, round with five deep furrows, ſlightly twiſted, and terminated by a ſhort ovate ſpike, imbricated with black ſcales, and enlivened with the prominent cream-coloured anthers, in its more advanced ſtate. A ſpike will ſometimes contain one hundred and thirty ſmall flowers, crowded cloſe together, with an ovate pointed ſcale or bracte at the baſe of each. The capſule contains two oblong ſhining ſeeds, of an amber colour in each cell. The ſtalks continue to grow after the flowering is over, and ſometimes ſhoot out to the length of two feet or more. When it grows in meadows the leaves are erect and drawn up; but in a dry barren ſoil, they are ſhorter, broader, and more ſpread on the ground [d].

It grows ſpontaneouſly by the ſides of roads, and in dry paſtures, where it is left untouched by cattle, to feed ſmall birds with the copious produce of its ſeeds. It has been generally conſidered as a weed, occupying the room of graſſes and other uſeful herbs; but it has lately been introduced into culture, under the name of *Rib-graſs*, as a good food for ſheep, or to be made into hay for cattle in general. Haller attributes the richneſs of the milk in the alpine dairies to this plant and *Alchemilla vulgaris*, or Ladies mantle. Linneus ſays, it is eaten by horſes, ſheep and goats, but that cows refuſe it. Sheep will eat it either green or dried, provided it be well gotten; but it does not anſwer for paſturage, without a mixture of clover or graſſes [e]. The total abſence, ſays Dr. Withering, of this plant, in marſhy lands, is a certain criterion of their wretched quality. In proportion as ſuch foils are improved by draining, it will flouriſh and abound. Ribwort Plantain however, at leaſt in England, is not a criterion of excellence in a ſoil, but merely of its dryneſs.

Mr. Curtis, Dr. Withering, and Dr. Smith do not ſpeak favourably of this plant, as a paſture or meadow herb. Certainly from theory one ſhould decide againſt it: but practical men hold it in ſome eſteem.

Mr. Zappa of Milan, affirms that *P. lanceolata* grows ſpontaneouſly in every meadow of Lombardy, eſpecially in thoſe which are irrigated; that it vegetates early, flowers at the beginning of may, ripens in five weeks, and is cut with *Poa trivialis*; that the height of the leaves is about one foot, and of the ſtalk a foot and half; that it multiplies itſelf much by the ſeed, and a little by the roots, which it continues for ſome time to reproduce; that it is eaten heartily by every ſort of cattle, and in particular by the cows in graſs, and the cows like it moſt in may, having great influence on the milk; that the hay is eaten more voraciouſly by cows, and has on them great influence in the

[p] Withering, Smith, Curtis. [q] Jacquin. [r] Linn. ſpec. [s] Hort. kew. [t] Jacquin. [u] Hort. kew. [x] Smith and Curtis.

[y] Lin. ſyſt. [z] Hort. kew. [a] Jacquin. [b] Knocker. [c] Hort. kew. [d] Curtis, Withering, Engl. bot. Fl. ruſt. [e] With. Engl. bot. Fl. ruſt.

fleſh; in ſhort, that it is one of the beſt plants either for the milk or the fleſh [r].

Mr. Young informs us, that he had long before recommended this plant for laying land to graſs, and ſowed it on his own farm [s]. At the ſame time he looks upon it as extravagant to propoſe Dandelion and Sorrel, as plants proper for a cow-paſture; and conjectures that thoſe plants, being found among good ones, have qualities given them which do not properly belong to them [t]. I am inclined to make the ſame conjecture of narrow-leaved Plantain, Ribwort or Rib-graſs, and ſhould even have preferred Dandelion and Sorrel to it: but I am cautious of oppoſing theory to practice.

Mr. Zappa adds, that *P. major* or great Plantain, grows not only along the roads, near dunghills, in damp and fat places, but in irrigated meadows alſo of every diſtrict in Lombardy; though more near the borders than in the centre of them; that it vegetates later, flowering towards the end of may; that the leaf is ſix inches long, and the ſtalk almoſt a foot high; that notwithſtanding it is not tender, every ſort of cattle like it, and that cows are as fond of this as of the other ſpecies [u].

Dr. Anderſon obſerves that narrow-leaved Plantain or Rib-graſs is well liked by horſes and cattle, and yields a very good crop upon rich ground tending to dampneſs, if it is at the ſame time ſoft and ſpongy; but that upon any ſoil which has a tendency to bind, or upon dry ground, it furniſhes a very ſcanty crop [x].

Narrow-leaved Plantain has been adopted in ſome parts of Yorkſhire as a ſummer graſs. As an article of paſturage for cattle and ſheep it is there in high eſteem: it is not however well affected by horſes; and as an article of hay it is held to be detrimental to the crop; retaining its ſap an unuſual length of time; and when fully dry, falls into a ſmall compaſs, or is broken into fragments, and left behind in the field. One advantage of this plant is, that its ſeeds may be eaſily procured genuine. A ſmall proportion of it may be eligible: it has now ſtood the teſt of twenty years eſtabliſhed practice, and ſeems to be ſtill in good eſtimation, even among obſervant huſbandmen [y].

Mr. Marſhall made a trial of it in Norfolk, as a ſubſtitute for Clover, but gained no credit from the experiment: the fact is, horſes do not affect it, and they are the principal conſumers of the Clover crop in that country [z].

The qualities of this ſpecies ſeem to be nearly the ſame with thoſe of *P. major*; and it is more uſed than that by the common people, where it is more common.

It varies much in ſize of the plant, breadth of the leaves, &c. The narrow leaves have only three ribs. The ſpike is ſometimes ſurrounded by large leaves, inſtead of the uſual ſmall bractes: it ſometimes becomes an abortive panicle: and it is found with two or three heads.

9. Native of the Cape of Good Hope, where it was found by Thunberg [a].

10. Leaves nerveleſs, pubeſcent underneath, brown at the tip and at the obſolete toothlets. Spike ſubglobular. Calyxes hirſute. Border of the corolla even [b].

According to Monſ. Desfontaines, the leaves are five-nerved. Scape pubeſcent, ſtriated, ſlender. Spike ſhort, ovate, cloſe, ſilky with very ſoft hoary villoſe hairs; when mature cylindrical.

Native of the South of France, Spain, Portugal and Algiers.—Cultivated in 1683, by Mr. James Sutherland. It flowers in june and july [c].

11. Stem ſimple, villoſe. Leaves like thoſe of the preceding, acute, toothletted or quite entire, running down into the petiole, which is ſheathing at the baſe. Peduncles round, not ſtriated, villoſe, twice or thrice as long as the leaf. Spike cloſe. Bractes ovate, concave, elliptic, ſcarioſe at the edge, longer than the calyx. Segments of the corolla ovate. It is allied to *P. amplexicaulis* of Cavanilles, *n.* 137. *t.* 125. but differs in having the leaves ciliate only, not hirſute all over. Perhaps it may be only a variety. Native of the ſands about Tozzer [d].

12. Leaves upright, wider than in *P. media*. Scapes longer than the leaves, ſomewhat hiſpid, five-grooved. Spike like that of *P. Lagopus*, but oblong, with ſhort hirſute bractes. Corolla white, with a yelloviſh ſtreak. Stamens white. Style elongated, pubeſcent, white [e].

According to Desfontaines, the leaves are oval-oblong, nerved, toothletted, running down into a ſhort petiole, tomentoſe at the baſe, and attenuated both ways. Scape ſtriated, ſmooth, except at top where it is a little villoſe, with hairs preſſed cloſe. Spike ovate-cylindrical, covered with a ſoft down.

Native of Spain; and near La Calle, in Barbary.—Introduced in 1781, by P. M. A. Brouſſonet, M. D. It flowers in july and auguſt [f].

13. This is very nearly allied to the next ſpecies, but the leaves are narrower, more linear and nerveleſs. It is an annual plant; and native of Champion river in Patagonia [g].

14. Leaves narrow-lanceolate, decurrent into the petiole, three-nerved or five-nerved, quite entire or very ſeldom toothletted, villoſe with white very crowded hairs, preſſed cloſe. Scape pubeſcent, ſcarcely ſtriated, erect. Spike when mature a little interrupted. Rachis villoſe. Bractes concave, ovate, membranaceous at the edge, the length of the calyx. Segments of the corolla ovoid, ſharpiſh, ruſeſcent. Anthers thick, yellow. Style ſtanding out, filiform, pubeſcent [h].

Native of the South of France, Spain and Barbary.—Introduced in 1770, by Monſ. Richard. It flowers from june to ſeptember, and is perennial [i].

Willdenow is of opinion, that *P. minuta* of Pallas (*it.* 2. *t.* E. *f.* 1.) ſcarcely differs from this, except in ſize.

15. Leaves ſilky with villoſe hairs preſſed cloſe, very ſharp, and attenuated at the baſe. Scape round, pubeſcent, ſlender, a little longer than the leaves. Spike when young ovate, but when the fruit is ripe cylindrical, very cloſe. Bractes ovate, acute, membranaceous at the edge, ſhorter than the flower. Corolla pale ruſeſcent, with the ſegments ovoid and ſmooth. It is allied to *P. albicans*, but has a ſhorter ſpike, round, with the flowers very much crowded, not interrupted when the fruit is ripe. Native of the ſands near Caſſa in Barbary [k].

16. Native of the Cape of Good Hope, where it was found by Thunberg [l].

17. Root perennial, oblique, branched, creeping a little, often as it were bitten off. Leaves nerved, two, three, or four lines in width, dark-coloured, ſmooth, thick and a little fleſhy. Spike very ſhort, round, compoſed of from eighteen or twenty to thirty flowers, which are much larger and more detached than in *P. lanceolata*. According to Krocker, before the flowers open it hangs down; and after flowering it becomes long and cylindrical. The bractes are as long again as the calyx; the corollas are blackiſh; according to Haller, they are whitiſh. The capſules are ſmooth and diſtinct [m].

Native of the mountains of Switzerland, Auſtria and Siberia.—Introduced in 1774, by William Pitcairn, M. D. [n]

18. This is a ſmall annual plant, often ſcarcely an inch, ſometimes an inch and half in height. Several of the leaves are an inch and half long, others are ſmaller; all are linear-lanceolate and acute, attenuated at bottom, obſcurely three-nerved. Scape upright, ſhorter than the larger leaves, ſordidly ſhaggy. Spike ovate or ovate-oblong, hirſute, the length of half the ſcape. Bractes lanceolate, attenuated, the length of the calyx. Segments of the corolla lanceolate [o].

Desfontaines has adopted Lamarck's name of *P. Holoſtea*; and remarks that it differs from *P. albicans*,

to which it is allied, in having the hairs ſpreading not preſſed cloſe, the ſpike ſhorter and denſer, the bractes awl-ſhaped, and the ſegments of the corolla very ſmall. He adds, that the leaves are quite entire and three or five-nerved; the ſcape round not ſtriated, a little longer than the leaves; the bractes awl-ſhaped, the lower ones longer than the flower; the calyx villoſe.

Native of Spain, Italy and Tunis.

19. This is an annual plant; when cultivated having the leaves longer and not ſo cloſely woolly, and upon the whole putting on a very different appearance from the wild plant [f].—Native of Crete.

20. Native of Terra del Fuego, where it was found by Forſter.

21. This puts up ſeveral very ſhort ſtems from the ſame head. Leaves quite entire, ſilky with hairs preſſed cloſe, ſharp, attenuated below. Scapes villoſe, round not ſtriated, ſhorter than the leaves or a little longer. Bractes ovate, concave, pubeſcent, membranaceous at the edge, ciliate at the tip, the length of the calyx; which is villoſe, and has elliptic ſegments. Corolla of a pale ruſous colour.

Native of the ſandy deſert near Caſſa and Elhammah. Annual [a].

22. Root perennial, woody, inverſely conical at the crown. Stalk five or ſix inches high. Spike from an inch to an inch and half in length, bent at a right angle before flowering. Leaves convex on the lower, channelled on the upper ſurface, generally entire, but ſometimes with a few minute irregular teeth. Bractes keeled. Tube of the corolla woolly. Anthers yellow [f].

No plant varies more in ſize than this: its leaves being ſometimes ſcarcely an inch, at other times more than a foot in length. The height of the ſtalk is more conſtant, but the number of flowers in the ſpike varies extremely. It loves a muddy ſoil, but is as various in its place of growth as in ſize, being found, like Statice Armeria, on the higheſt mountains as well as on the ſea ſhore. Hence it has been taken for *P. alpina*, which is a very different plant, with ſhort oval ſpikes, and lanceolate flat leaves. Still leſs reſemblance has our Sea Plantain, (though it has ſometimes toothed leaves, eſpecially on the coaſt,) to *P. Loeflingii*; that having flat leaves, and very ſhort roundiſh pale ſpikes, much like thoſe of *P. Pſyllium*.

Our *P. maritima* may be known by its very fleſhy and ſmooth leaves, channelled above and concave (convex) below, with a tuft of wool at their baſe, and the ſpike, however ſhort, always cylindrical [a].

It is common on the ſea coaſt and in ſalt marſhes, in many parts of Europe, Barbary, and North America, flowering rather late in the ſummer. It alſo grows in the fiſſures of rocks on mountains remote from the ſea. Mr. Robſon found it near Bernard Caſtle, thirty-five miles from the Sea; and Mr. Lightfoot on the ſummits of the higheſt mountains in Scotland.

Dr. Withering notices two varieties. One *narrow-leaved*, with filiform leaves, a much ſmaller plant than the common ſort, and flowering earlier. He found it in the Iſle of Wight, going out of flower the beginning of June. Leaves about two inches long. Stalk cylindrical, ſlender, not ſcored, four inches high. Spike an inch long, cylindrical, not cloſely crowded with florets.

The other *flat leaved*, with flat ribbed leaves very ſparingly toothed. Leaves five inches long, flat, five-ribbed. Stalk about five inches high, cylindrical. Spike two inches long, cylindrical, bent at a right angle before flowering. Bractes with a mid-rib, but not keeled. Obſerved near the Briſtol channel, by Mr. Swayne; and at Yarmouth, by Mr. Woodward.

23. Leaves cluſtered, filiform, acute, flat above, convex underneath, rugged about the edge with ſcarcely conſpicuous prickles; woolly at the root. Scape round, longer than the leaves, by no means ſmooth. Spike ovate-oblong, not villoſe [b].

[a] Willdenow. [b] Desfontaines. [f] Withering.
[f] Engl. bot. [b] Linn. ſpec.

Leaves, according to Desfontaines, awl-ſhaped, ſtriated, quite entire, ſtiffiſh, many from the ſame tuft, very much crowded together. Scape filiform, not ſtriated, much longer than the leaves. Spike ſlender, cloſe.

Native of the South of Europe, eſpecially on the ſandy ſhores of the Mediterranean; growing in thick tufts; alſo about Tlemſen, in Barbary.—Introduced in 1773, by John Earl of Bute [f].

24. Leaves ſmooth, with a ruſeſcent down at the baſe. Spike ſlender not interrupted.—Native of Barbary near la Calle [b].

25. Plant ſtemleſs. Leaves radical, acute, ſomewhat pubeſcent underneath, ſcarcely toothletted. Scapes filiform, round, not ſtriated, erect, ſhorter than the leaves. Corolla ſcarioſe. Stamens ſcarcely longer than the tube of the corolla. Piſtil longer. It is allied to *P. fabulata*: and perhaps may be the ſame cultivated in a garden. It is an annual plant, native of the South of Europe and the Levant [f].

26. Leaves radical, ſpreading like a roſe, narrowing very much towards the baſe, thick, hirſute on both ſides, mucronate; teeth ovate, three or five on each ſide, imbricate, mucronate, thickened at the edge. Scape aſcending, a hand or more in height, covered cloſely with hairs preſſed to it. Spike cylindrical hirſute, two inches and more in length. Bractes ovate, acuminate, ſpreading at top, purpliſh on the back, membranaceous at the edge, hirſute on the outſide. The two outer ſegments of the calyx hirſute; the inner convex, ciliate [w].

Desfontaines deſcribes it under the name of *P. crithmoides*, as a low tufted plant, hirſute, branched, decumbent at the baſe. Root thick, twiſted, ſomewhat woody. Leaves crowded, running down into the petiole, hirſute, deeply toothed: teeth acute, ſomewhat remote. Petioles tomentoſe at the baſe, ſheathing. Scape extremely villoſe, erect, longer than the leaves. Spike very cloſe, villoſe. Bractes awl-ſhaped, a little longer than the flower, ſetaceous at the top. Corolla ruſeſcent, with ſmall, ovate, acute ſegments.

Native of Sicily and Barbary. Found by Poiret in the plains of Mazoule, by Vahl at way-ſides about Tunis, by Desfontaines in the fiſſures of rocks on the coaſt.

27. Leaves ſtriated, ſubpubeſcent, ſubpetioled, ſerrated with ſharp teeth. Scape pubeſcent [a].

Desfontaines deſcribes the leaves as almoſt like thoſe of *P. lanceolata*, villoſe, ſerrated with awl-ſhaped, longiſh, remote, ſpreading teeth. Scape not ſtriated, longer than the leaves, villoſe with hairs preſſed cloſe. Spike cloſe ſlender. Segments of the corolla ſmall, acute.

Native of Sileſia, Apulia and Barbary. Krocker ſays he found it on the banks of the Oder and other rivers, in a clayey ſoil. Desfontaines in Algiers. Poiret informs us that this handſome ſpecies grows, with ſome varieties, in ſhady moiſt places.

28. Root annual. Leaves pinnatifid (ſometimes bipinnatifid) hairy, with very unequal ſegments, lying on the ground in form of a Star, whence the fanciful names of *Herba Stella* and *Star of the Earth*. Scapes aſcending, from four to ſeven inches high. Spike cylindrical, from an inch or an inch and half to two inches in length; in ſandy ground few-flowered, and ſo ſhort as to be almoſt headed. Segments of the calyx lapping over each other, deeply divided, and fringed at the outer edge. Anthers terminated by a ſmall lanceolate tranſparent membrane; which is conſtant, however the plant may vary in the ſize and cleſts of the leaves, height of the ſtalk, or length of the ſpike [a]. Capſule ovate-conical. Seeds in each cell four, ſmall, angular, ruſeſcent, with a white, ventral navel. Embryo ſtraight, yellow. Cotyledons very long, linear [f].

Native of moſt parts of Europe, Barbary, &c. in ſandy and gravelly ſoils, and on the ſea coaſt; flowering all the ſummer.

[f] Hort. kew. [b] Desfontaines. [f] Linn. mant.
[w] Vahl. [a] Linn. ſpec. [a] Withering. Smith.
[f] Gaertner.

Many varieties of this ſpecies are mentioned by different authors. But the ſpecies of this genus are much ſubject to variation. Linnæus remarks, that the tenth, twelfth, fourteenth, nineteenth, twentieth, and twenty-ſecond ſpecies are ſo nearly allied, that we may conjecture their difference to be owing to change of place, or the mixture of pollen.

P. Loeflingii, which has been confounded both with this ſpecies, and *P. maritima*, is very diſtinct from both, as may appear from the deſcription that follows.

29. This differs from *P. Coronopus* in being ſmaller and earlier, in having an ovate ſpike, with the flowers more thinly imbricate; the bractes ſmooth and boat-ſhaped, whereas in that they are awl-ſhaped, very narrow, and pubeſcent. The ſtamens are ſhorter; the leaflets of the calyx more acute; the corolla of a browner colour. The leaves are linear, not lanceolate, and ſparingly toothed. The ſcape is hairy. It is an annual plant; native of Spain, on hills and the borders of fields[a].

30. Root fuſiform, a finger in thickneſs, whitiſh. Leaves numerous, ſpread out in a circle, acute, with ſoft hairs ſcattered over the ſurface and along the edge, half a foot in length: rib channelled: pinnas ſeſſile, irregularly placed, linear, quite entire, or ſometimes but ſeldom gaſhed. Scapes very many, aſcending, cloſely villoſe, rugged, the length of the leaves. Spike linear, three inches long, round, leafleſs, upright, ſlender. Bractes ovate-acuminate, concave, equalling the calyx; the leaflets of which are lanceolate, equal, keeled, acuminate, hiſpidly ciliate. Corolla whitiſh; tube the length of the calyx, ſegments ovate, acuminate[b].

It is very nearly allied to *P. Coronopus*, but is more ſmooth, with the ſegments of the leaves unequal, and a very long ſtyle[c].

Its place of growth is unknown. Jacquin received the ſeeds from Gouan, under the name of *Pl. Cornuti*.

31. The plant of this exactly reſembles *Pl. lanceolata*, but the ſtem is about the length of the little finger (whereas that has no ſtem) and upright. Leaves ſomewhat fleſhy, narrowed at the baſe and embracing, beſet with ſcattered hairs. Peduncles long, in the axils of the leaves. Heads ſubovate[d]. It is an annual plant, native of Spain.

32. Stems diffuſed, villoſe. Lower leaves oppoſite; upper leaves in threes or fours, linear, recurved, toothed, villoſe-viſcid. Peduncles longer than the leaf. Heads leafleſs, with the bractes and calycine leaflets linear[e].

Root ſlender, annual, fuſiform. Stem ſtiffiſh, upright, jointed, round, tinged here and there with purple. Lower leaves obſcurely toothed; upper ones quite entire. Peduncles axillary, villoſe rigid. Spikes oval, ſhort, ſurrounded only with lanceolate bractes. Corollas ſharply four-cleft, of a whitiſh bay colour. Seeds ſmall, brown, oblong, ſhining, convex on one ſide, concave on the other[f].

Native of the South of Europe, Barbary, and the Canary iſlands.—Cultivated here in 1562, as appears from Turner's herbal. It flowers in july[g].

33. This, according to Jacquin, flowers in the ſtove, from june to auguſt, after which it ripens its ſeed. From a white annual root proceeds a weak ſtem, incurvated at the baſe, and from thence ſoon after its origin, oppoſitely branched, round, villoſe, and half a foot high; ſometimes it grows extremely branchy. Leaves ſublinear, quite entire, acute, oppoſite, ſeſſile, villoſe, roughiſh, tubercinated, from one to four inches long, ſubciliated, and that particularly below. Spikes oblong, terminal, pedunculated, axillary, upright, leafy, and ſubviſcid. Flowers ſolitary in the boſoms of the floral ſpikes, forming a leafy ſpike, exactly anſwering to the Linnean character. Calycine leaves equal, and green, covered with white viſcid hairs. Petal pale. Anthers browniſh: whole ſtyle villoſe and white[h].

Native of Egypt. Introduced in 1787, by Mr. Ziet. It flowers in auguſt and ſeptember[i].

[a] Loefling in Linn. ſpec. [b] Linn. ſpec. [c] Jacquin. [d] Jacquin. [e] Krocker. [f] Jacquin. [g] Hort. kew. [h] Willdenow. [i] Hort. kew.

34. The two lower leaflets of the calyx are ſpatulate, very blunt, and concave within. Corollas tubular, frequently double the length of the calyx[a].

Native of Egypt and India. Gmelin found it about Aſtracan.—Cultivated in 1683, by Mr. James Sutherland. It flowers in july and auguſt[b].

35. This is ſo like the *Plantago Indica* of Linnæus, that at firſt ſight it might paſs for a ſmall variety of it. It is an annual, tender, or weak plant, about a ſpan high. Root ſmall, growing more and more ſlender as it deſcends; and fibrilloſe at the edges. Stem erect, variouſly bent, round, thin, beneath compoſed of branches decuſſating oppoſitely, ſpreading, half a palm's length, and with internodes of about two inches. Leaves ſubulate, channelled, very ſpreading, reflected at the tip, oppoſite, the upper ones ſometimes ternate and quaternate, about a palm's length, pubeſcent on the margins or ciliated. Heads leafy, with ſetaceous hirſute bractes, of which the two lowermoſt are almoſt twice the length of the head, incurved; the reſt ſeated, like chaff among the ſtraighter floſcules. Peduncles ſolitary, filiform, hirſute, terminal and axillary, rather ſhorter than the leaves, ſpreading. Calyx equal to the corolla, and divided almoſt to the very baſe, with ſetaceous upright diſtant leaflets. Corolla with a ventricoſe wrinkled tube. Stamens four, longer than the corolla. Piſtil the length of the corolla. Seed one in each cell, navicular, brown[c].

36. Stem hard, woody, purpliſh, naked. Leaves oppoſite, awl-ſhaped or filiform, channelled and three-cornered, upright, ſubvilloſe. Peduncles axillary, the length of the leaves. The lower ſcales of the head mucronate, patulous, of a middling length. Bractes ovate, concave[d].

It differs from *P. Pſyllium*, in having a perennial fuſiform root; the ſtem not villoſe but naked, ſhrubby, purpliſh, procumbent, then erect, diffuſed; leaves oppoſite, quite entire, erect, ſubvilloſe, whereas thoſe of the other are patulous and villoſe: the peduncles are only equal to or ſhorter than the leaves and ſolitary; the ſpikes are encircled with leaves and ſcales[e].

Native of the South of Europe, Barbary, and Siberia.—Cultivated in 1596, by Gerarde. It flowers from may to auguſt[f].

The ancients made a mucilage of the ſeeds by decoction both from this ſpecies and *Pl. Pſyllium*. It was eſteemed lubricating and pectoral, provided the ſeeds were neither bruiſed nor over boiled, the kernel being acrid[g]. They are now neglected.

37. Stem a foot high, upright, pubeſcent. Leaves ſubvilloſe, ſtriated. Spikes ſeveral at the ends of the branches[h].

Native of Sicily, and Barbary, in the kingdom of Tunis, along the coaſt of the iſland of Tabarque[i].

38. Root long, ſlender, twiſted, deſcending, putting out here and there capillary fibres. Stems herbaceous, ſeveral from one tuft, ſlender, pubeſcent. Leaves often bowed, ſomewhat rigid, thickiſh. Heads of flowers ſmall, ſtiff, ſeſſile or pedunculed. Peduncles ſhorter than the leaf. Bractes linear-awl-ſhaped, very ſmall. Corolla minute: ſegments ovoid, acute, pale ruſeſcent. It is an annual plant; native of Barbary, in the great deſert[k].]

Of this genus, Mr. Miller only ſays, that theſe plants being rarely cultivated in gardens, he ſhall only mention ſuch as grow naturally in England. 1. The common broad-leaved Plantain (P. major) called Waybread. 2. The great hoary Plantain (P. media) or Lamb's-tongue. 3. The narrow-leaved Plantain (P. lanceolata) or Ribwort: with the varieties, called Beſom and Roſe Plantain. They grow common in paſtures, and are frequently very troubleſome weeds.

Of the Coronopus or Buck's-horn Plantain there are two varieties growing in Britain: the common, which is plentiful on heaths; and the narrow-leaved, which is found upon many of the Welſh mountains. The firſt of theſe was formerly cultivated as a ſalad herb in

[a] Linn. ſyſt. [b] Hort. kew. [c] Murray. [d] Linn. ſpec. [e] Krocker. [f] Hort. kew. [g] Villars. [h] Linn. ſpec. [i] Poiret. [k] Desfontaines.

gardens,

gardens, but has been long baniſhed for its rank diſagreeable flavour. *Pl. Pſyllium* or Fleawort has been found in the earth thrown out of the bottom of the canals, which were dug for the Cheſea water-works. They are ſometimes imported from the South of France for medical uſe.

PROPAGATION AND CULTURE.

Theſe plants are ſeldom to be ſeen except in Botanic gardens, having little beauty. [The greater part are hardy enough to bear the open air in our climate. They riſe eaſily from ſeeds, of which they produce great abundance, and require no nicety in the cultivation. Some few, as n. 3. 9. 16. 33. 34. require the protection of the dry ſtove; and ſeveral of them muſt be ſcreened from froſt in ſevere winters.

PLANTING.

Although the method of Planting the various ſorts of trees is fully ſet down under their ſeveral articles, where each kind is mentioned, yet it may not be amiſs to ſay ſomething in general upon that head in this place, which ſhall be treated as briefly as poſſible. And,

Firſt, the firſt thing in Planting trees is to prepare the ground (according to the different ſorts of trees intended to be planted) before the trees are taken out of the earth; for you ſhould ſuffer them to remain as little time out of the ground as poſſible.

In raking up the trees you ſhould carefully dig away the earth round their roots, ſo as to come at their ſeveral parts to cut them off; for if they are torn out of the ground without care, the roots will be broken and bruiſed very much to the great injury of the trees. When they are taken up, the next thing is to prepare them for Planting; in doing which there are two things to be principally regarded; the one is to prepare the roots, and the other to prune their heads, in ſuch a manner as may be moſt ſerviceable in promoting the future growth of the trees.

And firſt as to the roots; all the ſmall fibres are to be cut off as near to the place from whence they are produced as may be (excepting ſuch trees as are to be replanted immediately after they are taken up;) otherwiſe the air will turn all the ſmall roots and fibres black, which, if permitted to remain on when the tree is planted, will grow mouldy and decay, and thereby greatly injure the new fibres which are produced, ſo that many times the trees miſcarry for want of duly obſerving this. After the fibres are cut off, all the bruiſed or broken roots ſhould be cut ſmooth, otherwiſe they are apt to rot and diſtemper the trees; and all irregular roots which croſs each other, and the downright roots, (eſpecially in fruit-trees) muſt be cut off; ſo that when the roots are regularly pruned, they may in ſome meaſure reſemble the fingers of a hand when ſpread open; then the larger roots ſhould be ſhortened in proportion to the age and ſtrength of the tree, as alſo the particular ſorts of trees are to be conſidered; for the Walnut, Mulberry, and ſome other tender-rooted kinds ſhould not be pruned ſo cloſe, as the more hardy ſorts of fruit or foreſt-trees, which in young fruit-trees, ſuch as Pears, Apples, Plums, Peaches, &c. that are one year old from budding or grafting, may be left about eight or nine inches long; but in older trees they muſt be left of a much greater length; but this is to be underſtood of the larger roots only, for the ſmall ones muſt be quite cut out, or pruned very ſhort. Their extreme parts, which are generally very weak, commonly decay after moving, ſo that it is the better way entirely to diſplace them.

The next thing is the pruning of their heads, which muſt be differently performed in different trees, for the deſign of the trees muſt alſo be conſidered; if they are fruit trees, and intended for walls or eſpaliers, it is the better way to plant them with the greateſt part of their heads, which ſhould remain on until the ſpring, juſt before the trees begin to ſhoot, when they muſt be cut down to five or ſix eyes (as is fully inſerted in the ſeveral articles of the various kinds of fruit) being very careful, in doing of this, not to diſturb the new roots.

But if the trees are deſigned for ſtandards, you ſhould prune off the ſmall branches cloſe to the places where they are produced; as alſo irregular branches which croſs each other, and by their motion, when agitated by the wind, rub and bruiſe their bark, ſo as to occaſion many times great wounds in thoſe places; beſides, it makes a diſagreeable appearance, and adds to the cloſeneſs of its head, which ſhould always be avoided in fruit trees, whoſe branches ſhould be preſerved as far diſtant from each other, as they are uſually produced when in a regular way of growth, (which is in all ſorts of trees proportionable to the ſize of their leaves, and magnitude of their fruit) for when their heads are very thick, which is often occaſioned by the unſkilful ſhortening of their branches, the ſun and air cannot freely paſs between the leaves, ſo that the fruit muſt be ſmall and ill-taſted. But to return: after having diſplaced theſe branches, you ſhould alſo cut off all ſuch parts of branches, as have by accident been broken or wounded; for theſe will remain a diſagreeable ſight, and often occaſion a diſeaſe in the tree. But you ſhould by no means cut off the main leading ſhoots, as is by too many practiſed, for thoſe are neceſſary to attract the ſap from the root, and thereby promote the growth of the tree; for from ſeveral experiments which I made in the winter of 1729, by cutting off the branches of ſeveral ſorts of trees, and putting them into phials filled with water, whoſe tops were cloſely covered to prevent the evaporating of the water, I found, that thoſe ſhoots, whoſe leading buds were preſerved, did attract the moiſture in much greater quantities than thoſe ſhoots whoſe tops were cut off; and from ſeveral experiments made by the Rev. Dr. Hales, we find that great quantities of moiſture are imbibed at wounds, where branches are cut off; ſo that by thus ſhortening the branches, the wet, which generally falls in great plenty during the winter ſeaſon, is plentifully imbibed, and for want of leaves to perſpire it off, mixes with the ſap of trees, and thereby diſtending the veſſels, deſtroys their contracting force, which many times kills the tree, or at leaſt weakens it ſo much as not to be recovered again for ſome years, as I have ſeveral times obſerved.

But being willing to try this experiment again in the month of October 1733, I made choice of two ſtandard Almond-trees of equal ſtrength and age; theſe I took up as carefully as poſſible, and having prepared their roots as before directed, I pruned their heads in the following manner, viz. from one of them I only cut off the ſmall branches, and ſuch as were bruiſed or broken, but preſerved all the ſtrong ones entire; of the other, I ſhortened all the ſtrong branches, and pruned off the weak and broken ſhoots, as is the common practice. Theſe two trees I planted in the ſame ſoil and to the ſame ſituation, gave them both equal attendance, and managed them both as nearly alike as poſſible; yet in the ſpring, when theſe trees began to ſhoot, that, whoſe branches were entirely preſerved, came out early, continued to ſhoot ſtronger, and is at preſent much larger, and in better health than the other. And ſince this I have made ſeveral other experiments of the like nature, which have conſtantly ſucceeded in the ſame manner, from whence it is reaſonable to conclude, that the ſhortening of the branches is a great injury to all new-planted trees, but eſpecially to Cherries and Horſe Cheſtnuts, which are frequently killed by ſhortening their large branches when they are removed.

Having thus prepared the trees for Planting, we muſt now proceed to the placing them into the ground; but before this, I would adviſe, if the trees have been long out of the ground, ſo that the roots are dried, to place them in water eight or ten hours before they are planted, obſerving to put them in ſuch manner, that their heads may remain erect, and their roots only immerſed therein, which will ſwell the dried veſſels of the roots, and prepare them to imbibe nouriſhment from

from the earth. In fixing them, great regard ſhould be had to the nature of the ſoil, which if cold and moiſt, the trees ſhould be planted very ſhallow; as alſo, if it be a hard rock or gravel, it will be much the better way to raiſe a hill of earth where each tree is to be planted, than to dig into the rock or gravel, and fill it up with earth (as is too often practiſed), whereby the trees are planted, as it were in a tub, there being but little room for their roots to extend; ſo that after two or three years growth, when their roots have extended to the ſides of the hole, they are ſtopped by the rock or gravel, can get no farther, whereby the trees will decline, and in a few years die; beſides, theſe holes detain the moiſture ſo, that the fibres of the plants are often rotted thereby. But when they are raiſed above the ſurface of the ground, their roots will extend and find nouriſhment, though the earth upon the rock or gravel be not three inches thick, as may be frequently obſerved, where trees are growing upon ſuch ſoils.

The next thing to be obſerved is to place the tree in the hole in ſuch manner, that the roots may be about the ſame depth in the ground, as they were growing before they were taken up; then break the earth fine with a ſpade, and ſcatter it into the hole, ſo that it may fall in between every root, that there may be no hollowneſs in the earth (but you ſhould by no means ſift or ſcreen the mould, for reaſons given in ſome other places); then having filled in the earth, you ſhould gently tread it cloſe with your feet, but do not make it too hard, which is a very great fault, eſpecially if the ground is ſtrong and inclinable to bind.

Having thus planted the trees, you ſhould provide a parcel of ſtakes; one of which ſhould be driven down by the ſide of the trees, and faſtened thereto to ſupport them from being blown down or diſplaced by the wind; then lay ſome mulch upon the ſurface of the ground, about their roots, to prevent the earth from drying.

This is to be underſtood of ſtandard-trees which caſt their leaves; for ſuch as are planted againſt walls, ſhould have their branches faſtened to the wall to prevent the trees from being diſplaced by the wind; but there is no difference in their management, only to preſerve their heads entire, and to place their roots about five inches from the wall, inclining their heads thereto; and the ſpring following, juſt before they ſhoot, their heads ſhould be cut down to five or ſix buds, as is fully directed under the ſeveral articles of the different kinds of fruit.

As to the watering of all new-planted trees, I ſhould adviſe it to be done with great moderation, nothing being more injurious to them than over-watering. Examples enough of this kind may have been ſeen in many parts of England, where plantations have been over-watered, whereby the greateſt part of the trees have failed, or thoſe which have ſurvived, have made little progreſs, occaſioned by the abundance of water given to them, whereby the fibres were rotted off as ſoon as produced. And how can any perſon imagine that a tree ſhould thrive, when the ground, in which it is planted, is continually flooted with water? for by an experiment made by the Rev. Dr. Hales, in placing the roots of a dwarf Pear-tree in water, the quantity of moiſture imbibed decreaſed very much daily, becauſe the ſap-veſſels of the roots, like thoſe of the cut-off boughs in the ſame experiment, were ſo ſaturated and clogged with moiſture, by ſtanding in water, that more of it could not be drawn up. And this experiment was tried upon a tree which was full of leaves, and thereby more capable to diſcharge a large quantity of moiſture than ſuch trees as are entirely deſtitute of leaves; ſo that it is impoſſible ſuch trees can thrive, where the moiſture is too great about their roots.

The ſeaſons for planting are various, according to the different ſorts of trees, or the ſoil in which they are planted; for ſuch trees whoſe leaves fall off in winter, the beſt time is in the middle or end of october, provided the ſoil be dry; but for a very wet ſoil, it is better to defer it until the latter end of february, or the beginning of march; and for many kinds of Evergreens, the beginning of april is by far the beſt ſeaſon, though ſome ſorts may be ſafely removed at midſummer, provided they are not to be carried very far; but you ſhould always make choice of a cloudy ſeaſon, if poſſible, at that time of the year, when they will take freſh root in a few days. And, on the contrary, when theſe trees are removed in winter, during which time they are almoſt in a ſtate of reſt, they do not take root until the ſpring advances, and ſets the ſap in motion; ſo that many times they die, eſpecially if the winter proves ſevere.

As to the preparing the ſoil for Planting, that muſt alſo be done to ſuit the different ſorts of trees, ſome requiring a light ſoil, others a ſtrong one, &c. But this is fully ſet down in the ſeveral articles of trees, under their proper heads, to which the reader is deſired to turn; though for the fruit-trees in general, a freſh ſoil from a paſture ground, which is neither too light and dry, nor over-ſtrong and moiſt, but rather a gentle, ſoft, loamy earth is to be preferred, provided it be expoſed ſome time. And if it be for wall trees, will be the better if the borders are filled with this earth ſix or eight feet wide, but it need not be above two feet and a half deep at moſt; for when the borders are made too deep, the roots of theſe trees are enticed downward, which is of bad conſequence to fruit-trees, as hath been elſewhere obſerved. The ſame alſo muſt be obſerved for ſtandard-trees (where freſh earth is brought to the places in which they are planted), not to make the holes too deep, but rather let them have the ſame quantity of earth in width, which is much to be preferred.

There are ſeveral perſons who direct the placing the ſame ſide of the tree to the ſouth, which before removing had that poſition, as a material circumſtance to be ſtrictly regarded; but from ſeveral trials which I have made, I could not obſerve the leaſt difference in the growth of thoſe trees which were ſo placed, and others which were reverſed; ſo that I conclude, it is not of any conſequence to obſerve this method.

The diſtance which trees ſhould be planted at, muſt alſo be proportioned to their ſeveral kinds, and the ſeveral purpoſes for which they are intended, all which is explained under their ſeveral heads; but fruit-trees, planted either againſt walls, or for eſpaliers, ſhould be allowed the following diſtances: for moſt ſorts of vigorous-ſhooting Pear-trees, from thirty-ſix to forty feet; for Apricots, ſixteen or eighteen feet; Apples, twenty-five or thirty feet; Peaches and Nectarines, twelve feet; Cherries and Plums, twenty-five feet, according to the goodneſs of the ſoil or the height of the wall. But as theſe things are mentioned in the ſeveral articles of fruit trees, it will be needleſs to repeat any more in this place.

What hath been mentioned on this article chiefly relates to fruit-trees and evergreens, for gardens; but I ſhall now proceed to the planting of foreſt and other trees, which are in all large plantations of parks and extenſive gardens the moſt numerous. The modern practice of tranſplanting theſe ſorts of trees, from hedge-rows and woods, of large ſizes, and at a great expenſe, has too generally prevailed in this kingdom, the generality of planters being in too great haſte, and by a miſtaken notion of ſaving time, begin by tranſplanting ſuch large trees as they find on their own eſtates, or that they can procure in their neighbourhood, and pleaſe themſelves with the hopes of having fine plantations ſoon; but if, inſtead of removing theſe trees, they would begin by making a nurſery, and raiſing their trees from ſeeds, they would ſave a great expenſe and much time, and they would have the conſtant pleaſure of ſeeing their trees annually advance in their growth, inſtead of growing worſe, as will always be the caſe where old trees are removed, though many perſons flatter themſelves with the hopes of ſucceſs, when they find their trees ſhoot out the following ſeaſon; and as theſe will often continue to grow for ſome years after, they continue their expectations, till after waiting many years, in which time they might have had ſeedling trees grown up to a fine ſize, if they had been ſown at the time the large trees were planted, they find their trees annually decaying, when they

they moſt expected their increaſe; and of all the plantations which I have yet ſeen of theſe large trees of any ſort, there is ſcarce one which has ever ſucceeded.

In ſome of theſe plantations, all the Elms which could be procured from the neighbouring hedge-rows have been removed, moſt of which having been ſuckers produced from the old ſtumps, have ſcarce any roots: theſe have, at a great expenſe, been planted and watered, and perhaps many of them have made conſiderable ſhoots, the whole length of the ſtem at every knot, and many of them have continued ten or twelve years alive, but have not increaſed in the girt of their ſtems half an inch, and all that time have been decaying at their heart, and growing hollow; ſo that when a ſevere froſt in winter, or a great drought in ſummer, has happened, there has been an almoſt total deſtruction of the trees.

In other places I have ſeen great numbers of tall Oaks tranſplanted, which have appeared to thrive for ſome years when firſt planted; but in five or ſix years after have begun to decay at their top, and have leiſurely died to the ground, than which nothing can be a more diſagreeable ſight to the owner. And the method which is commonly practiſed in tranſplanting theſe trees would deſtroy them, were there a poſſibility of ſuch large trees ſurviving their removal, which is, that of cutting off all their branches; for, were the ſame practiſed on a tree of the ſame age unremoved, it would ſtint the growth ſo much as not to be recovered in ſeveral years, nor would it ever arrive to the ſize of ſuch as have all their branches left on them. But the reaſon given for this practice is, that if the branches were left upon the trees, they could not be ſupported, the winds would throw them out of the ground; and another (which is bad philoſophy) is, that as the roots have been greatly reduced by tranſplanting, ſo the heads of the trees ſhould be reduced in the ſame proportion. As to the firſt, it muſt be allowed, that trees which are removed with great heads, are with great difficulty preſerved in their upright ſituation; for the winds will have ſuch power againſt the branches as to overſet the trees, if they are not very ſtrongly ſupported with ropes. Therefore this may be brought as an objection to the tranſplanting of large trees, rather than in ſupport of a practice which is ſo prejudicial to them: and as to the other reaſon, it has no foundation; for if large amputations are made at the root, there ſhould not be the ſame practiſed on the head, becauſe the wounded part of the head will imbibe the air at every orifice, to the great prejudice of the tree. Beſides this, if we pay any regard to the doctrine of the circulating of the juices in plants, we muſt allow, that the heads of the trees are equally uſeful to nouriſh the roots, as the roots are to the heads; ſo that if there is a waſte of ſap both at the top and bottom of the trees, it muſt weaken them in proportion. For whoever will be at the trouble to try the experiment on two trees of equal age and health, and cut the branches off from one, and leave them upon the other at the time of tranſplanting, if the latter is well ſecured from blowing down, it will be found to ſucceed much better than the other; or if the ſame thing is practiſed upon two trees left ſtanding, the tree whoſe branches are cut off, will not make half the progreſs as the other, nor will the ſtem increaſe in its bulk half ſo faſt. Therefore where trees are tranſplanted young, there will be no neceſſity for uſing this unnatural amputation, and the ſucceſs of theſe plantations will always give pleaſure to the owner. I have ſeen ſome plantations of Oak-trees, which were made fifty years ago, and had thriven beyond expectation moſt part of the time, but are now annually decaying, and ſeem as if they would not continue many years longer, when the trees on the ſame ſoil and in the ſame ſituation, which were left ſtanding, are in perfect health and vigour; and ſome of theſe tranſplanted trees which have been cut down, were found to be of little value, their timber being ſhaken and bad.

It is common to hear perſons remarking that from the preſent ſpirit of Planting, great advantages will accrue to the public by the increaſe of timber; but whoever is the leaſt ſkilled in the growth of timber muſt know, that little is to be expected from moſt of the plantations which have lately been made; for there are few perſons who have had this in their view when they commenced planters, and of thoſe few ſcarce any of them have ſet out right; for there never was any valuable timber produced from trees which were tranſplanted of any conſiderable ſize, nor is any of the timber of the trees which are tranſplanted young, equal in goodneſs to that which has grown from the ſeeds unremoved. Beſides, if we conſider the ſorts of trees which are uſually planted, it will be found, that they are not deſigned for timber; ſo that upon the whole, it is much to be doubted, whether the late method of planting has not rather been prejudicial to the growth and increaſe of timber, than otherwiſe.

Before I quit this ſubject of Planting, I muſt beg leave to obſerve, that moſt people are ſo much in a hurry about Planting, as not to take time to prepare their ground for the reception of trees, but frequently make holes and ſtick in the trees, amongſt all ſorts of rubbiſh which is growing upon the land; and I have frequently obſerved, that there has not been any care afterwards taken to dig the ground, or root out the noxious plants; but the trees have been left to ſtruggle with theſe bad neighbours, who have had long poſſeſſion of the ground, and have eſtabliſhed themſelves ſo ſtrongly, as not to be eaſily overcome; therefore, what can be expected from ſuch plantations? This is to be underſtood of deciduous trees, for the Pines and Firs, if once well rooted in the ground, will ſoon get the better of the plants and deſtroy them.

There are ſome other perſons who begin better than the former, and who will be at the expenſe of preparing the ground and of planting their trees, but afterwards take very little care of them; ſo that it is common to ſee them overgrown with weeds in a year after they are planted, whereby the trees receive ſo much injury as to retard their growth, and many times, if the trees are young, they are totally deſtroyed. Therefore I would adviſe every perſon who propoſes to plant, to prepare the ground well before-hand, by trenching or deep ploughing it, and clearing it from the roots of all bad weeds; for by ſo doing, there will be a foundation laid for the future ſucceſs of the plantation. Alſo I adviſe no perſon to undertake more of this work than he can afterward keep clean, for all plantations of deciduous trees will require this care, at leaſt for ſeven years after they are made. Therefore all ſmall plantations ſhould have the ground annually dug between the trees; and as to thoſe which are large, it ſhould be ploughed between them. This will encourage the roots of the trees, to extend themſelves, whereby they will find a much greater ſhare of nouriſhment, and by looſening the ground, the moiſture and air will more eaſily penetrate to the roots, to the no ſmall advantage of the trees. But beſides this operation, it will be abſolutely neceſſary to hoe the ground three or four times in ſummer, either by hand or the hoe-plough. This I am aware will be objected to by many, on account of the expenſe; but if the firſt hoeing is performed early in the ſpring, before the weeds have gotten ſtrength, a great quantity of ground may be gone over in a ſhort time; and if the ſeaſon is dry when it is performed, the weeds will preſently die after they are cut; and if this is repeated before the weeds come up again to any ſize, it will be found the cheapeſt and very beſt huſbandry; for if the weeds are ſuffered to grow till they are large, it will be a much greater expenſe to root them out, and make the ground clean; beſides, the weeds will rob the trees of great part of their nouriſhment. I have ſometimes been told, that it is neceſſary to let the weeds grow among trees in ſummer, in order to ſhade their roots, and keep the ground moiſt, but this has come from perſons of no ſkill; but as others may have been deceived by ſuch advice, I imagine it may not be improper to give ſome anſwer to this. And here I muſt obſerve, That if weeds are permitted to grow, they will draw away all moiſture from the roots of the trees for their own nouriſhment, ſo that the trees will be thereby deprived

of the kindly dews and the gentle ſhowers of rain, which are of great ſervice to young plantations; and theſe will be entirely drawn away by the weeds, which will prevent their penetrating the ground, ſo that it is only the great rains which can deſcend to the roots of the trees. And whoever has the leaſt doubt of this matter, if they will but try the experiment, by keeping one part of the plantation clean, and ſuffer the weeds to grow on another, they will ſoon be convinced of the truth by the growth of the trees. And though this cleaning is attended with an expenſe, yet the ſucceſs will overpay this, beſide the additional pleaſure of ſeeing the ground always clean.

In the diſpoſition of trees in parks, and of ſhrubs and trees in gardens, there are very few of thoſe who call themſelves deſigners, who have had much regard to this particular; for in moſt of the modern plantations, it is not uncommon to ſee an Oak, an Elm, or ſome other large-growing tree planted where a Roſe-buſh, a Honeyſuckle, or Sweet-briar, might with more propriety occupy the ſpace: ſo that in a few years, if theſe large trees are left growing, the whole plantation muſt make a diſagreeable appearance. See NURSERY and WOODS.

DESCRIPTIONS, *&c.*

1. The firſt ſort, or Eaſtern Plane-tree, grows naturally in Aſia, where it becomes very large; the ſtem is tall, erect, and covered with a ſmooth bark, which annually falls off; it ſends out many ſide branches, which are generally a little crooked at their joints; the bark of the young branches is of a dark brown, inclining to a purple colour; the leaves are placed alternate, on foot-ſtalks an inch and a half long; the leaves themſelves are ſeven inches long and eight broad, deeply cut into five ſegments, and the two outer are ſlightly cut again into two more; theſe ſegments have many acute indentures on their borders, and have each a ſtrong midrib, with many lateral veins running to the ſides; the upper ſide of the leaves is of a deep green, and the under ſide pale. The flowers come out upon long peduncles hanging downward, each ſuſtaining five or ſix round balls of flowers; the upper, which are the largeſt, are more than four inches in circumference; theſe ſit very cloſe to the peduncle. The flowers are ſo ſmall as ſcarce to be diſtinguiſhed without glaſſes; they come out a little before the leaves, which is the beginning of June; and in warm ſummers the ſeeds will ripen late in autumn, and if left upon the trees will remain till ſpring, when the balls fall to pieces, and the briſtly down which ſurrounds the ſeeds, helps to tranſport them to a great diſtance with the wind.

[Du Roi remarks, that the leaves vary in figure, but are always ſmooth; and that the peduncles are brown. Pallas ſays, that the leaves, when young, are white-tomentoſe; but when old, the petioles only are ſo; that the peduncles are ſmooth; that it differs moſt from the Occidental Plane-tree in having ſcarcely any ſtipules on the adult branches; and that the wood is very hard, reddiſh with browniſh-gray tranſverſe ſtreaks.

Gærtner thus deſcribes the fruit.—Pericarp none, unleſs the ſuberous or corky cruſt of the ſeed be taken for it. Common integument globular, corky, attended on every ſide by the ſeeds heaped together very cloſely, when mature naked, without any viſible ſcale. Seed naked, club-ſhaped, from an awl-ſhaped peduncle, compreſſed a little or ſomewhat angular, thickened into a globular head, and dagger-pointed with the permanent ſtyle or ſtigma; at the baſe crinite with fulvous ſimple ſtraight hairs, not exceeding the head in length. Integument double: outer thick, ſomewhat woody, not opening, but eaſily ſplit from the baſe upwards, ſo that it may be taken for a capſule: inner membranaceous, very thin, pale. Albumen none. Embryo oblong, compreſſed, inverted, yellowiſh, much ſhorter than the ſhell of the ſeed. Cotyledons linear, ſomewhat leafy. Radicle roundiſh, ſuperior.

Native of the Levant, and many other parts of Aſia. On mount Taurus, Athos, Macedonia, Lemnos, Crete, moſtly near water[1]. In Perſia and perhaps Georgia, where there are very handſome trees, four yards in circumference; on mount Caucaſus, where it is very common, it takes the form of a large ſhrub; as the American Plane does, in the gardens at St. Peterſburgh[2].

The Plane Tree has always been much eſteemed in the Eaſtern countries, where it grows naturally, for its beauty, and grateful ſhade. Evelyn, Miller, and Gilpin have related at length, from Ælian, the adoration that was paid by Xerxes, to a tree of this ſort in

[1] Linn. [2] Pallas.

Phrygia.]

Phrygia.] And wherever any ſumptuous buildings were erected in that country, the porticoes, which opened to the air, generally terminated in groves of lines of theſe trees.

[It was no leſs eſteemed in Italy after it was introduced there. Pliny informs us, that it was firſt brought over the Ionian ſea, into the iſland of Diomedes, for a monument to that hero; thence it paſſed into Sicily, and ſo into Italy [s]. It was planted near their houſes, and in rows for walks; and was even irrigated with wine.]

Pliny affirms, that there is no tree whatſoever which ſo well defends us from the heat of the ſun in ſummer, or that admits it more kindly in winter; the branches being produced at a proportional diſtance to the largeneſs of the leaves; (which holds good in all ſorts of trees yet known): ſo that when the leaves are fallen in winter, the branches eaſily admit the rays of the ſun. [Virgil calls the Platanus *ſterilis*, not becauſe it bears no ſeed, but no fruit that is eatable.]

Mr. Miller ſays, it is generally ſuppoſed, that the introduction of this tree in England is owing to the great lord chancellor Bacon, who planted a noble parcel of them at Verulam, which were very flouriſhing ſome years ſince, but have lately been deſtroyed.

[Mr. Evelyn alſo ſays—the introduction of this true Plane among us, is *perhaps* due to the great lord chancellor Bacon, who planted thoſe, ſtill flouriſhing ones (1706) at Verulam. He adds, that he owed a hopeful plant then growing at his own villa to the late Sir George Crook, of Oxfordſhire. He ſpeaks of the true Plane of antiquity, as being very rare in England in his time, and of the American Plane as more common.]

Mr. Miller alſo informs us, that there were very few large Oriental Plane Trees to be ſeen; which he thinks might be owing to the great eſteem perſons of the laſt age had for the Lime Tree, which being much eaſier to propagate, and of quicker growth during the three or four firſt years, became more faſhionable for avenues and ſhady walks near habitations.

[But we had the Oriental Plane-tree in England certainly before the time of Lord Bacon; for it appears from Turner's herbal, that it was cultivated here as early as 1562 [t]: whereas the Chancellor was born only in 1561. The plantations however at Verulam might be the firſt of any note or conſideration.

Mr. Boutcher from Evelyn, and he from Rieciolus, ſays that the Turks uſed to build moſt of their ſhips with this timber; that it was hard, cloſe, takes a fine poliſh, and is valuable for a variety of uſeful purpoſes. Mr. Marſhall, ſeemingly with more reaſon, ranks this wood with that of the Great Maple, vulgarly called Sycamore, and in the North of England Plane Tree.

With us it is conſidered merely as an ornamental tree, and is not ſo common as the American Plane even in ornamental plantations.] Notwithſtanding its backwardneſs in coming out in the ſpring, and the ſudden decay of its leaves in autumn, yet for its goodly appearance, and the great ſize to which it will grow, the Oriental Plane deſerves a place in all large plantations, or ſhady receſſes, eſpecially near the manſion, or on a moiſt ſoil and near ſtreams of water, in which ſituations it will arrive at a prodigious magnitude.

[Lady Craven ſpeaks of ſome which ſhe ſaw in the Turkiſh dominions of a ſize ſo gigantic, that the largeſt trees we have in England, placed near them, would appear only like broomſticks.

Pauſanius tells us of a Plane-tree of extraordinary ſize and beauty in Arcadia, ſuppoſed to be planted by Menelaus; ſo that the age of the tree, when Pauſanias ſaw it, muſt have been about thirteen hundred years [u]. That the tree was large and handſome we may believe, but no tradition can be ſufficient to perſuade us that a Plane-tree ever attained ſuch an age, provided it was found when Pauſanias ſaw it.

Pliny mentions other remarkable Plane-trees: as one in Lycia that had mouldered away into an immenſe cave, eighty feet in circumference. Licinius Mutianus, governor of that province, with eighteen others dined commodiouſly on the benches of pumice placed round the body of it.

Caligula alſo had a tree of this ſort at his villa near Velitræ. The hollow of the trunk held fifteen perſons at dinner, with a proper ſuite of attendants [x].]

That which is called Maple-leaved Plane is certainly a ſeminal variety of the Eaſtern Plane, for the ſeeds which ſcattered from a large tree of this variety in the Chelſea garden have produced plants of the common ſort ſeveral times. The Maple-leaved Plane has not its leaves ſo deeply cut as thoſe of the Eaſtern Plane: they are divided into five ſegments, pretty deep, but are not lobed, like thoſe of the Occidental Plane. The petioles are much longer than in either of the ſpecies, and the upper ſurface of the leaves is rougher, ſo that they might be taken for different ſorts, if we did not know that they roſe from the ſame ſeeds.

The Spaniſh Plane-tree has larger leaves than either of the ſorts; and are more divided than thoſe of the Occidental, but not ſo much as thoſe of the Oriental. Some of the leaves are cut into five, and others into three lobes only; theſe are ſharply indented on the edges, and are of a light green; the foot-ſtalks are ſhort, and covered with a ſhort down. This is by ſome called the middle Plane-tree, from the leaves being of a ſhape between the two ſpecies.

2. The ſecond ſort grows naturally in moſt parts of North America; this tree alſo grows to a large ſize, the ſtem very ſtraight, and of equal girt moſt part of the length; the bark is ſmooth, and annually falls off like that of the other: the branches extend wide on every ſide; the young ones have a browniſh bark, but the old ones have a gray bark; the foot-ſtalks of the leaves are three inches long; the leaves are ſeven inches long, and ten broad; they are cut into three lobes or angles, and have ſeveral acute indentures on their borders, with three longitudinal midribs, and many ſtrong lateral veins. The leaves are of a light green on their upper ſide, and paler on their under. The flowers grow in round balls like the former, but are ſmaller. The leaves and flowers come out at the ſame time with the former, and the ſeeds ripen in autumn.

[Kalm, who calls it the Virginian Maple, ſays that it grows in plenty on the ſhores of the Delaware. The Engliſh Americans call it Button-wood, (from the catkins or aments) or Water Beech, which is more common. It grows moſtly in low places, but eſpecially on the edge of rivers and brooks. It is eaſily tranſplanted to drier places, if the ſoil be good; and as the leaves are large and the foliage thick, it is planted about houſes and in gardens, to afford a pleaſant ſhade in the hot ſeaſon. It likewiſe grows in marſhes and in ſwampy fields, with the Aſh and Red Maple. It is remarkable for its quick growth; and is frequently as tall and thick as the beſt Fir trees. There are ſuch numbers of them on the low meadows between Philadelphia and the ferry at Glouceſter, on both ſides of the road, that in ſummer it is a ſhady walk all the way. In Philadelphia near the Sweediſh church, ſome great Plane-trees ſtand on the ſhore of the river.

It appears from Parkinſon that the American Plane was introduced here before 1640, by Mr. John Tradeſcant, junior [y]. Johnſon, in his additions to Gerarde's herbal, printed in 1633, mentions that there were two young ones at that time growing with Mr. Tradeſcant. He does not ſeem indeed to have known that theſe were of a different ſpecies from thoſe which Gerarde ſays his ſervant William Marſhal (whom he ſent into the Mediterranean ſea as ſurgeon unto the Hercules of London) found growing in Lepanto, hard by the ſea ſide, at the entrance into the town, a port of Morea; and from thence brought one of the rough bottons, being the fruit thereof. Theſe were Oriental Planes; but there is no doubt that the young trees growing with Mr. Tradeſcant were Occidental Planes.

[s] Martyn's Virg. Georg. p. 70. p. 121. [t] Hort. kew.
[u] Gilpin's Forest scenery, vol. 1. p. 50 and 125.
[x] Idem. p. 123 to 125. [y] Hort. kew.

In more than a century and half it has not become very common, although, as Mr. Marſhall ſays, it is particularly refreſhing to the eye, and truly ornamental; the bright colour giving variety to groves and maſſes of wood; and in ſingle trees or groups being ſingularly elegant.

The ſtem of the Occidental Plane, ſays Mr. Gilpin, is very picturesque: it is ſmooth and of a light aſh colour, and has the property of throwing off its bark in ſcales; thus naturally cleanſing itſelf, at leaſt its larger boughs, from moſs and other paraſitical incumbrances.

No tree forms a more pleaſing ſhade. It is full-leaſed, and its leaf is large, ſmooth, of a fine texture, and ſeldom injured by inſects. Its lower branches ſhooting horizontally, ſoon take a direction to the ground; and the ſpray, by twiſting about in various forms, fills up every little vacuity with ſhade. At the ſame time it muſt be owned, the twiſting of its branches is a diſadvantage, when the tree is ſtripped of its leaves, and reduced to a ſkeleton. Nor indeed does its foliage, from the largeneſs of the leaf, and the mode of its growth, make the moſt picturesque appearance in ſummer. The ſummer-leaf alſo both of this and the Oriental Plane, wears ſo light a hue, as to mix ill with the foliage of the Oak, the Elm, and other trees. On the ſkirts of a plantation they ſometimes form, during the ſummer, a diſagreeable ſpot. In autumn, their leaves receive a mellow tint, which harmonizes very well with the waning colour of the wood.

One of the fineſt Occidental Planes, adds Mr. Gilpin, ſtands in my own garden at Vicar's-hill, where its boughs, feathering to the ground, form a canopy of above fifty feet in diameter.

At Shadwell Lodge in Norfolk, the ſeat of John Buxton, Eſq. a Plane Tree was planted in april 1744; it was then eight feet high. In april 1775, the height was ſixty-five feet nine inches; the girt at half a foot from the ground was ſeven feet nine inches; at twenty feet, four feet ſix inches[a].]

PROPAGATION AND CULTURE.

1. The Eaſtern Plane-tree is propagated either from ſeeds, or by layers, the latter of which is generally practiſed in England; though the plants thus raiſed ſeldom make ſo large ſtraight trees, as thoſe which are produced from ſeeds; but it has been generally thought that the ſeeds of this tree were not productive, becauſe they have not been ſown at a proper ſeaſon, nor managed in a right manner; for I have had thouſands of the young plants ſpring up from the ſeeds of a large tree, which ſcattered upon the ground in a moiſt place: and I ſince find, that if theſe ſeeds are ſown ſoon after they are ripe, in a moiſt ſhady ſituation, they will riſe extremely well; and the plants thus obtained, will make a conſiderable progreſs after the ſecond year, being much hardier and leſs liable to loſe their tops in winter, than thoſe which are propagated by layers. And ſince the ſeeds of this tree frequently ripen well in England, they may be propagated in as great plenty as any other foreſt-tree.

2. The Virginian Plane-tree will grow extremely well from cuttings, if they are planted the beginning of october upon a moiſt ſoil; and if they are watered in dry weather, will make a prodigious progreſs; ſo that in a few years from the planting, they will afford noble trees for planting avenues, and other ſhady walks; and their trunks are perfectly ſtraight, growing nearly of the ſame ſize to a conſiderable height, there being the leaſt difference in the girt of this tree, for ſeveral yards upwards, of any ſort of tree whatſoever. The Hon. Paul Dudley, Eſq. in a letter to the Royal Society, mentions one of theſe trees, which he obſerved in New England, whoſe girt was nine yards, and held its bigneſs a great way up, which tree, when cut down, made twenty-two cords of wood. He alſo ſays, in the ſame letter, that he had propagated many of theſe trees by cutting off ſticks of five or ſix feet long, and ſetting them a foot deep into the ground in the ſpring of the year, when the ſeaſon was wet, and that they always thrive beſt in a moiſt ſoil.

[a] Hunter's Evelyn.

Both ſorts are propagated very eaſily by layers, in march every twig of them will take root, if they are but pegged down and covered with earth; theſe layers will be well rooted in one year, when they ſhould be cut off from the old trees or ſtools, and planted in a nurſery, where they may remain two or three years to get ſtrength, after which they may be tranſplanted where they are to remain, for the younger theſe trees are planted the better they will thrive. An experiment of this I made in 1731, when I planted four of theſe trees, in the ſame ſoil and ſituation, at about twenty feet diſtance from each other; one of which, viz. the Spaniſh Plane, whoſe ſtem was eight inches in girt; next to this, one of the Maple-leaved Plane-tree, whoſe girt was not three inches, but the latter is now much larger than the former, and gains more in one year than the other does in three; and the two others which were of a middle ſize, have grown in a mean proportion between them.

[In the winter ſcreen the ſeed-beds with pea-ſtraw, rotten tanner's bark, or ſome other light covering, that can eaſily be removed in mild weather. In the ſpring, before the ſeeds vegetate, rake the beds gently over with a ſhort-toothed rake, ſifting a little freſh rich mould on them, and in dry weather during ſummer let them be watered. The following autumn, the beds having been made quite clean, put a little more good mould about the plants; after which they will require no farther trouble, but keeping them clean, till they have had another ſeaſon's growth, when they may be removed into the nurſery in ſpring[b]: in rows one yard aſunder, and eighteen inches diſtance in the rows.—Though many of the ſeeds will come up the firſt ſpring; yet the general crop muſt not be expected till the ſecond.

Dr. Hunter recommends the cuttings to be taken from ſtrong young wood, and planted early in autumn, in a moiſt good mould. They are generally planted thick, and then removed into the nurſery: but if a large piece of moiſt ground be ready, the cuttings may be placed at ſuch a diſtance, as not to approach too near each other, before they are of a ſufficient ſize to plant where they are to remain, which would ſave the expenſe and trouble of a removal. The Eaſtern Plane will alſo grow from cuttings, but not ſo certainly[c].

Mr. Boutcher recommends cuttings of the Weſtern Plane, to be planted at the beginning of march, in ſhady borders, two feet row from row, and eight or ten inches in the rows: if they are torn aſunder at the joints with a knob of the old wood left, they will grow more readily. Theſe cuttings ſhould be a foot or fourteen inches long, and buried about eight inches deep. In two years they may be removed.

However propagated, after two years they may be planted out, in rows three feet and a half aſunder, and eighteen inches in the rows, there to remain, or be tranſplanted after three years to another nurſery, in rows ſix feet aſunder, and three feet in the rows, where they may ſtand ſix or ſeven years. The ſeaſon for tranſplanting the Planes is march, and they delight in a moiſt deep ground[d], eſpecially the American ſort. Where land is inclined to be dry, the two varieties are to be preferred[e].

PLATYLOBIUM. (*From* πλατυς *broad, and* λοβος, *a pod.*)

Smith in Linn. tranſ. 2. 350. *Nov. Holl. t.* 6.

Cheilococca. *Saliſb.*

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ.*

GENERIC CHARACTER.

Cal. bell-ſhaped, five-toothed: the three lower teeth acute and ſpreading; the two upper very large, obovate, obtuſe, cloſe preſſed to the ſtandard.

Cor. papilionaceous: *ſtandard* twice as long as the calyx, ſpreading, deeply emarginate: *wings* ſhorter than the ſtandard, ſemi-obovate, with a blunt incurved tooth on the upper ſide at their baſe: *keel* of two adhering petals, obtuſe, as long as the wings, with a tooth on

[b] Boutcher. [c] Hunter's Evelyn. [d] Boutcher. [e] Hunter.

each side of the base, embraced by the incurved teeth of the wings.

STAM. *Filaments* in one set, separated only on the upper side, and cloven nearly half their length; divisions equal and curved upwards. *Anthers* ten, nearly orbicular, equal, versatile.

PIST. *Germ* linear, very hairy. *Style* incurved, smooth. *Stigma* simple, sharp.

PER. *Legume* pedicelled, clothed with scattered hairs, somewhat scimeter-shaped, perfectly compressed, obtuse with a small point, one-celled, extending into a flat border along the upper edge, considerably beyond the insertion of the seeds.

SEEDS seven or eight, compressed, each on a curved white pedicel.

OBS. *This genus may be inserted near Crotalaria in the Linnean system.*

ESSENTIAL CHARACTER.

Cal. bell-shaped, five-cleft; the two upper segments very large and obtuse. *Legume* pedicelled, compressed, winged at the back.

SPECIES.

1. Platylobium formosum. *Orange Flat pea.*
Smith in Linn. trans. 2. 350. *nov. holl.* 17. *t.* 6.

DESCRIPTION, *&c.*

Stem shrubby, four feet high. Branches opposite, round, roughish, covered with leaves, and ornamented with numerous flowers. Leaves opposite, on very short hairy foot-stalks, cordate-ovate, entire, revolute, acute with a minute spine at the end, very veiny, rigid, of a beautiful green, glaucous beneath. Stipules in pairs, lanceolate, brown, membranous, striated, smooth. Flowers solitary, from the axils of the uppermost leaves, opposite, on short hairy peduncles. Bractes several, at the base of the peduncle, ovate, concave, hairy; and two at the top, immediately under the flower, somewhat longer. Calyx very hairy. Standard of the corolla orange-coloured, striated almost half way to the edge, with beautifully radiant crimson lines, from a pale-yellow spot at the base: wings deep yellow: keel whitish, tipped with a rich crimson. Pod an inch and half long, and half as broad.

Native of New South Wales, where it blooms all the year through [a]. Introduced about 1792.

PLECTRANTHUS. (*From πλεκτρον, a cock's spur, and ανθος, a flower, the corolla having a spur, which is singular in the order Gymnospermia of the class Didynamia, though common in the other order.* L'Herit.)

Lin. gen. Schreb. n. 987. *L'Herit. stirp.* 85. *t.* 41, 42. Germanica. *Lamarck. Juss. gen.* 116. 449.

Class. 14. 1. Didynamia Gymnospermia.

Nat. order of *Verticillatæ*. *Labiatæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, subcampanulate, short, bilabiate. *Upper lip* ovate, wider, ascending. *Lower lip* four-cleft, acute: the two lowest segments a little longer.

COR. monopetalous, ringent, resupine. *Tube* compressed, longer than the calyx. One lip turned upwards, wider, trifid; the middle segment larger, emarginate, the lateral ones small: the other lip turned down, narrower, entire, ovate, concave.

Nectary a spur or bump from the base of the tube of the corolla, produced upwards.

STAM. *Filaments* four, declined, awl-shaped, of which two are a little shorter. *Anthers* simple.

PIST. *Germ* four-parted. *Style* filiform, the length and situation of the stamens. *Stigma* bifid, acute.

PER. none; but the calyx contains the seeds at bottom.

SEEDS four, roundish.

ESSENTIAL CHARACTER.

Cal. upper segment larger. *Cor.* resupine: gibbous or spurred at the base. *Filam.* simple.

SPECIES.

1. Plectranthus fruticosus. *Shrubby Plectranthus.*
L'Herit. stirp. nov. 85. *t.* 41. *Ait. kew.* 2. 322.
Nectary spurred, racemes compound, peduncles three-parted, stem shrubby levigated.

[a] Smith in Linn. trans.

L'Herit. stirp. nov. 87. *t.* 42. *Ait. kew.* 2. 322.
Ocymum punctatum. *Linn. suppl.* 275.
Nectary gibbous, flowers in spikes, stem herbaceous roughhaired.

3. Plectranthus galeatus. *Helmet-flowered Plectranthus.*
Vahl symb. 1. 43.
Nectary gibbous, pedicels branched, leaves cordate-ovate acuminate serrate.

4. Plectranthus Forskahlæi.
Vahl symb. 1. 44.
Ocymum hadiense. *Forsk. descr.* 109.
Nectary gibbous, racemes leafless, stem equal.

5. Plectranthus crassifolius. *Thick-leaved Plectranthus.*
Vahl symb. 1. 44.
Ocymum Zatarhendi. *Forsk. descr.* 109.
Nectary gibbous, racemes bracted, leaves ovate fleshy.

DESCRIPTIONS, *&c.*

1. This is a handsome fragrant plant, with the habit of a Nettle. Stems several, erect, very much branched, brachiate, pithy, ash-coloured. Branches opposite, spreading, obscurely marked with lines, the thickness of a reed, brittle: tender shoots four-cornered, pubescent, green. Leaves broad-ovate or shaped like a heart, only they are not emarginate but produced at the base, acute or acuminate, doubly serrate, with equal bluntish waved serratures; wrinkled, nerved and veined, with the nerves and veins prominent on the lower surface only; villose, appearing dotted underneath when viewed with a magnifying glass, spreading, fragrant, four or five inches long, and three or four wide. Petioles spreading, longer than half the leaf, having one groove above, pubescent, sometimes pale purple. Racemes terminating, erect, compound or three-parted, four-cornered, villose, from three to six inches in length. Peduncles opposite, horizontal, three-flowered, round, villose. Flowers pedicelled. Corollas blue, five lines in breadth. Bracte under the peduncles, spreading, pressed close, subsessile, ovate, acute, villose. Calyx villose, three lines wide. Seeds brown, fastened to a fleshy subrostrated body, at the bottom of the calyx, as to a receptacle.

Native of the Cape of Good Hope [a]. Found there by Masson. Introduced here in 1774. It flowers from june to september [b].

2. This is an annual plant, a foot high, with a disagreeable smell. Stems a few, branching only at the base, fleshy, round, jointed; the lower joints more gibbous, and sometimes rooting; below they are purple, with very dark purple spots. Leaves ovate, acute, toothed, nerved, very much wrinkled, villose, commonly spotted with brown in the disk, the spot having stiffish brown hairs scattered over it, spreading, reclining, from two to three inches long, from eighteen to twenty-four lines wide, stinking. Petioles short, channelled. Spikes solitary, terminating; and besides this, others short and solitary from the upper axils, erect, compact, bracted, hirsute, two inches long. Flowers on short pedicels, in a sort of whorl, aggregate under each bracte, two or three lines in length. Corollas very pale blue, marked with purple lines on the disk of the upper lip; on the lower more intensely dotted towards the tip. Seeds compressed, of an ash-bay-colour.

The glands which are scattered over the corolla, and especially over the calyx in this species, are not found in *P. fruticosus*. The calyx is not really shaped like that of the Ophrys in this, as it is in that. The nectary of this is a bag not a spur. The upper lip is manifestly trifid in *punctatum*; but in *fruticosum* instead of the lateral segments of the upper lip, there are two toothlets at the side of the throat. Lastly the anthers are ovate in *punctatum*, four-cornered in *fruticosum* [c].

Native of Africa; where it was found by James Bruce, Esq. Introduced here in 1775. It flowers from january to may [d]. Monf. L'Heritier says it flowers in autumn, and marks it as annual. In the Kew catalogue it is marked as biennial.

[a] L'Heriter. [b] Hort. kew. [c] L'Heritier. [d] Hort. kew.

3. Stem villose, grooved. Leaves petioled, broad-ovate, villose, especially the veins underneath. Peduncle terminating: pedicels opposite, branched. Bractes none. Corollas pubescent, with the lower lip galeated. It approaches to Ocimum scutellarioides of Linneus; but that has ovate-lanceolate leaves, smaller flowers, cordate bractes, and a pair of peduncles on each side.—Native of Java.

4. Stem hirsute, not dotted. Leaves ovate, approximating towards the tops of the branches, hairy, very blunt, grosly crenate, transverse at the base, quite entire. Petiole only half the length of the leaf, a little dilated at the base. Racemes half a foot long, erect, composed of whorls having from eight to ten flowers. Pedicels filiform. Fruiting calyxes grooved, gibbous at the base underneath: the lower segments bristle-shaped, ascending. Corolla four times as long as the calyx: tube bent back a little, above the calyx, gibbous upwards.

Native of the mountains of Arabia Felix and Madagascar. The specimens from the latter are more villose and soft.

5. This differs from the preceding in having fleshy leaves, and membranaceous ovate bractes.

Native of Arabia Felix. Probably several species of Ocimum may belong to this genus[a].

PROPAGATION AND CULTURE.

1. This perfects seeds, and may be increased by them; as also freely by cuttings. It must have the protection of the dry stove.

2. This also commonly ripens its seeds, and is propagated only by them. It may be preserved in the dry stove or greenhouse. The other two species have not yet been cultivated in Europe.

PLECTRONIA. (*From* Πλεκτρον.)
Lin. gen. Reich. n. 300. *Schreb. n.* 389. *Juss.* 382.
Class. 5. 1. Pentandria Monogynia.
Nat. order of *Contortæ? Rhamni*, Juss.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, turbinate, obsoletely five-toothed, closed with sinuses or five villose scales; permanent.
Cor. *Petals* five, lanceolate, sessile, inserted into the throat of the calyx.
Stam. *Filaments* five, very short. *Anthers* geminate, roundish, each covered by the calycine scales.
Pist. *Germ* inferior. *Style* filiform, shorter than the calyx. *Stigma* ovate.
Per. *Berry* oblong, two-celled.
Seeds solitary, oblong, compressed.

ESSENTIAL CHARACTER.

Pet. five inserted into the throat of the calyx. *Berry* two-seeded, inferior.

SPECIES.

Myrtus brasiliana. *Lin. spec.* 674.
Eugenia uniflora. *Lin. spec.* 673.
Ibipitanga. *Marcgr. bras.* 187.
Flowers four-petalled.

DESCRIPTIONS, *&c.*

1. This is a tree, with abruptly pinnate leaves: leaflets about twelve, ovate-lanceolate, quite entire. Flowers sessile, scattered over the older naked branches. Fruit eatable.—Native of America[c].

2. Leaves opposite, petioled, simple, even, like those of Myrtle, ovate. Flowers peduncled, the length of the leaves, subumbelled. Calycine leaflets four, ovate, concave, spreading, coloured, reflex. Petals four or eight, obovate, sessile, twice as long as the calyx. Filaments very many, capillary, the length of the petals, inserted into the receptacle: anthers roundish. Germ inferior, roundish, angular. Style filiform, the length of the stamens. Stigma simple. Berry roundish, the size of a Plum, with eight swellings, one-celled, umbilicated with a four-toothed calyx, very like those of the other species, red and sapid. Seed single, subglobular[d].

Native of Brasil. Cultivated here in 1759, by Mr. Miller. It flowers in january and february. It is commonly cultivated in Madeira and the West Indies[e].

This species is thrice repeated by Linneus, twice in the *Species Plantarum*, under the names of *Eugenia* and *Myrtus*; and again in the thirteenth edition of *Systema Vegetabilium* and *Mantissa Plantarum*, under the name of *Plinia rubra*. See *Eugenia* and *Myrtus* in this Dictionary.

PLOCAMA. (Πλοκαμος, *a lock of hair.*)
Ait. hort. kew. 3. 508. *Lin. gen. Schreb. n.* 1738. *p.* 797.

Leaves ovate-oblong petioled scaly-dotted underneath, petioles eared embracing.]

DESCRIPTIONS, *&c.*

1. Root perennial, striking deep into the ground. Stalks many, slender, three feet and a half high, and channelled. Leaves three inches long and two broad, smooth, entire, of a grayish colour. The upper part of the stalks send out many slender side branches, which have small leaves on them. These, and also the principal stalks are terminated by tufts of either blue or white flowers, which are small, and succeeded by rough hairy seeds.

[The calyx has five tubercles at the base on the outside, besides the petioled glands[a].

Height, according to Villars, one foot. Stems hard, numerous, angular. Leaves oblong, very entire, a little rugged, of a blackish green. The calyx has glands on the angular lines that run along it longitudinally. Corolla of a dusky purplish colour.

Stem erect, smooth, angular, with panicled branches. Leaves alternate, smooth, lead-coloured, toothletted at the edge or quite entire, having two appendicles at the base: the lower stem-leaves blunt; the upper branch-leaves sharp. Flowers aggregate, terminating. Calyx round, five-parted: segments linear, approximating; with short hairs, glandular at top, disposed

[1] Linn. spec.

[a] Jacqu.

[a] Linn. syst.

in a double row. Corolla blue-violet, five-petalled; with linear claws, converging at the edge into a tube, twice as long as the calyx; border obovate, quite entire. Stamens shorter than the claws: filaments capillary. Style pubescent at bottom: stigmas five, villose-glandular. Germ superior[a].

Native of the South of Europe, and the kingdom of Tunis in Africa.—Cultivated in 1597, by Gerarde[b].] It seldom flowers in England till towards the end of october, and unless the autumn proves warm, does not flower at all; and never produces ripe seeds.

It is called Dentellaria in Latin, Dentellaire in French, and Toothwort in English, from its property of curing the tooth-ach; being of a hot caustic nature, like Pellitory of Spain.

[Two ounces of the plant boiled in four ounces of Olive oil is recommended to cure the itch; the sediment is tied up in a bag of linen, and the patient is rubbed with it, moistening the bag from time to time with the oil[c]. Allioni says that the leaves are too burning and inflammatory, and therefore prefers an infusion of the root, which he used with success himself. The root bruised is laid on the wrist, to heal the tooth-ach; it leaves a dark lead-coloured mark on the place, very difficult to be wiped off, whence the name of *Plumbago*, and if it remains on long enough, it burns the skin and leaves an ulcer. Some put it behind the ear, when it acts as a blister[d].

The Arabs make an ointment, by rubbing the leaves with salt and oil, for the itch, tetters, &c.[e]

2. This resembles the preceding, but is manifestly different; the stem being higher, the branches longer and divaricated, the leaves much larger and smooth, and the flowers only half the size.—Native of Iberia[f].

3. Native of the Cape of Good Hope[g].]

4. This is a perennial plant, with a strong fibrous root, from which arise many slender stalks, growing near four feet high. Leaves about three inches long, and an inch and half broad near their base, ending in acute points; they are alternate, and on short foot-stalks. The upper part of the stalks divides into small branches, having smaller leaves on them, and terminating in spikes of flowers. Seeds covered with the prickly calyx. The upper part of the stalks, and the calyx of the flowers are very glutinous, sticking to the fingers, and entangling small flies that settle on them.

[Native of the East Indies and of the Society Isles. Cultivated in 1731, by Mr. Miller. It flowers from april to september[h].

5. This is a shrubby plant, which frequently grows to the height of four or five feet, and is perpetually putting forth flowering spikes; these continue a long time, and hence, with proper management, it may be kept in flower during most of the year. The parts of fructification, whether we regard their colour or structure, are highly deserving of notice[i].

The calyx has capitate glutinous hairs scattered over it. The filaments are dilated at the base and arched. Capsule superior, clothed with the permanent calyx, ovate-oblong, ending in the subulate-setaceous style, obscurely five-cornered. Seed oblong, acuminate above, of a dark blood-red or ferruginous colour, suspended by a filiform umbilical chord, springing from the base of the capsule[k].

Native of the East Indies. Introduced into this country in 1777, by the late John Fothergill, M. D.[l]

6. Stem suffrutescent, scandent, sometimes decumbent, loose, flexuose, branched, round, striated, smooth. Leaves alternate, ovate-lanceolate, acuminate, nerved, spreading, entire, smooth on both sides: two smaller leaflets at the base of the middle, and two above it. Petioles very short, compressed, channelled, half embracing, membranaceous at the edge, with a red spot at the base underneath. Flowers terminating, subpanicled, commonly in spikes, sessile, scattered, approximating. Leaflets sessile under the flowers. Calyx inferior, bellying in the middle and towards the base, five-grooved, with glanduliferous hairs. Border of the corolla five-parted: parts roundish, emarginate, with a very short point in the middle. Nectaries roundish, yellow, round the germ, inserted into the bottom of the calyx. Filaments thickened, approximating, awl-shaped. Anthers placed on the top of the filaments, blue. Style the length of the stamens. Seed coated, as it were included in a capsule, and covered with the permanent calyx.

Native of South America, and Jamaica, in dry hedges[m].

The calyx sent by Jacquin proves his plant to be a species distinct from this[n].

Lamarck distinguishes this from *P. zeylanica*, by the segments of the corolla not being mucronate; whereas Swartz says that they have a very short point in the middle[o].

It was introduced here in 1778, by Henry De Ponthieu, Esq. and flowers in july and august[p].

7. Native of the East Indies.]

PROPAGATION AND CULTURE.

1. The stalks decay in the winter, and new ones come up the following spring. It may be increased by parting the roots, which send out heads in plenty. These may be divided at any time when the weather is mild, from the time the stalks decay, till the roots begin to shoot in the spring. It should have a light soil and a warm situation, otherwise it will not flower here. The roots should be allowed room to spread; the stalks require support; and if the plants are kept clean from weeds, and the ground is dug between them every autumn, that is all the culture they require.

4. This is propagated by seeds, sown on a good hot-bed in the spring. The plants will come up in five or six weeks. When these are fit to remove, plant each in a separate small pot filled with light loamy earth, and plunge the pots into a hot-bed of tan, observing to screen them from the sun till they have taken new root. In summer admit a large share of fresh air to them in warm weather, and water them moderately every other day. In winter keep them in a moderate warmth, and water them more sparingly.

[5. Increase this by cuttings, which strike freely. It is one of the most ornamental plants which we keep in our stoves[q].]

PLUMERIA. (*So named by Tournefort, in honour of Charles Plumier, of Marseilles, a Franciscan, traveller into South America, and author of several excellent works: as* Plantæ Americanæ, 1693, *and by Burmann in* 1755. Genera, 1703. Fougeres Americaines, 1705, &c.)

DESCRIPTIONS, *&c.*

1. Red Plumeria, called Red Jaſmine in Jamaica, riſes to the height of eighteen or twenty feet. The ſtalks are covered with a dark green bark, having marks where the leaves are fallen off; they are ſucculent, abound with a milky juice, and within are ſomewhat woody. Towards the top they put out a few thick ſucculent branches, with leaves at their ends of a light-green colour, full of milky juice, having a large midrib and many tranſverſe veins. At the ends of the branches alſo come out the flowers in cluſters; ſhaped like thoſe of the Oleander or Roſe-Bay, of a pale red colour, and having an agreeable odour.

[The flowers are ſo ſweet as well as beautiful, that the women in South America adorn their hair with them, and put them among linen to ſcent it, as we do Lavender [a].

They are produced in England in july and auguſt; and the whole plant loſes its foliage from the middle of winter till the beginning of may [b].

According to Linneus it is a native of Surinam. In the Kew catalogue, and by Mr. Curtis, it is ſet down as a native of Jamaica. Browne does not give it as indigeneus of that iſland.] Miller ſays it grows naturally in the Spaniſh Weſt Indies, where it is cultivated in the gardens for ornament. [Jacquin confirms this, ſaying that it ſeems to have been tranſported into the Caribbee iſlands from the American continent. The French there call it *Frangipanier rouge.* It was cultivated in 1690, in the Royal garden at Hampton-court [c].]

Mr. Miller has a variety of this, which he calls *Plumeria incarnata,* (n. 2.) He received it from the iſland of St. Chriſtopher, by the name of Japan-tree, with an account that it had then been lately introduced from the Spaniſh Weſt Indies. The ſtalks do not riſe ſo high as the preceding; the leaves are of a thicker conſiſtence, and the veins larger; the flowers are of a paler colour, and in much larger cluſters; it being common to have upwards of twenty open in one bunch, with a number to ſucceed theſe as they decay; ſo that the cluſters continue in beauty upwards of two months, during which time they make a moſt beautiful appearance in the ſtove, and have a very agreeable odour.

2. [This tree has the habit of Red Plumeria, but is not much branched, and rarely exceeds fifteen feet in height; it abounds like that in a milky juice. The flowers are white with a yellowiſh eye, and diffuſe a very ſweet odour to a conſiderable diſtance [a]: Linneus ſays, it is ambroſiac, and ſo ſtrong as to excite the head-ach; but that all powerfully ſweet ſmells will do in ſome conſtitutions, particularly in a hot day or a warm climate.

Linneus adds, that the flowers are in ſpikes, and that the leaves are rolled back on the ſides.]

Mr. Miller remarks, that this is not near ſo beautiful as the former; the flowers being ſmaller, produced in leſs bunches, and of ſhorter duration; but that for the beauty of the ſtem and leaves it deſerves a place in every curious collection. It grows plentifully at Campeachy, whence the ſeeds were ſent by Dr. Houſtoun, who alſo obſerved ſome plants of it at Jamaica. [Browne conſiders it as a native of that iſland; and Jacquin of Martinico, where the French call it *Frangipanier blanc.*

It was introduced by William Houſtoun, M. D. and cultivated by Mr. Miller before 1733 [b].]

3. This produces ſmall white flowers reſembling thoſe of the ſecond. [The leaves are oval-lanceolate; and the peduncles branched [a].

Loureiro deſcribes it as a thick tree, exceeding the middle ſize, with an aſh-coloured, ſmooth, milky bark, a juicy brittle wood, and ſpreading, thick, twiſted branches. Leaves quite entire, large, flat, ſmooth, ſcattered, with many tranſverſe ribs. Flowers terminating, in compound ſpreading upright racemes. Corollas odorous, white, mixed on the outſide with red, on the inſide with yellow. Calyx tubular, ſhort, deciduous, ſlightly five-cleft; ſegments rounded, erect. Corolla inferior; tube ſmall, curved. Filaments very ſhort, inſerted above the baſe of the tube: anthers oblong, erect. Style none. Stigmas two, conical. Seeds biggiſh, ſcale-form, ending in a membranaceous baſe. Linneus attributes blunt leaves to this tree; but Rumphius and Loureiro met with them always acute. Probably two different ſpecies have been confounded.]

Miller ſays his *Pl. nivea* was diſcovered by Dr. Houſtoun, growing in great plenty near Carthagena in the Spaniſh Weſt Indies, whence he ſent the ſeeds to England.

[Plumier found it in South America, and Cateſby in Carolina. According to the Kew catalogue, it is a native of the Weſt Indies, and was introduced in 1783, by John Greg, Eſq. If ſo, *P. obtuſa* is ſuppoſed to be different from Miller's *nivea.* If Rumphius's *Flos convolutus,* and Loureiro's *P. obtuſa* be the ſame with Linneus's *P. obtuſa,* it is alſo a native of Amboyna, China and Cochinchina, where it is alſo cultivated on account of the beauty and ſweet ſmell of the flowers.

4. This is an upright milky ſhrub, five feet in height, of the ſame habit with the others. Leaves oblong, flat, veined. Flowers numerous, yelloviſh, the border continuing erect and ſhut, even after they drop; being rolled up like the flowers of Hibiſcus or Achania Malvaviſcus: they ſucceed each other continually for two months together; and have an odour much more agreeable than that of the preceding ſpecies, or even of any other known flower. It is highly eſteemed at Curaçao, and is there called *Donzelle* from the property of the flower mentioned above. They cultivate it there in the gardens; but it is not known from what part of South America it was introduced [a].]

PROPAGATION AND CULTURE.

All theſe plants may be propagated by ſeeds procured from the countries where they grow. Sow them in pots filled with light earth; plunge them into a tan-pit, and when the plants are two inches high, tranſplant them ſeparately into ſmall pots filled with light ſandy earth; plunge them into the hot-bed again, ſhading them in the middle of the day, until they have taken root: they muſt not have much water, for being very ſucculent, much moiſture will cauſe them to rot. In hot weather the plants ſhould have a large ſhare of freſh air admitted to them, by raiſing the

[a] Jacquin. [b] Curtis. [c] Hort. kew.

[a] Jacquin. [b] Hort. kew. [a] Linn. [a] Jacquin.

glaſſes of the hot-bed every day, in proportion to the warmth of the ſeaſon, to prevent their drawing up weak. Towards michaelmas, when the nights begin to be cold, the plants ſhould be removed into the ſtove, and plunged into the bark-bed, where they muſt remain during the winter. As theſe plants all caſt their leaves in the middle of winter, and continue deſtitute of them till about the beginning of may, during that time, they ſhould be watered very ſparingly, becauſe they are in more danger of rotting, while they are in a leſs active ſtate, by too much moiſture, than when they are furniſhed with leaves, through which the moiſture is more freely perſpired.

All theſe ſorts are too tender to thrive in the open air of this country in the ſummer ſeaſon, therefore ſhould be conſtantly preſerved in the ſtove, where, in warm weather, they muſt have a large ſhare of free air, but in cold weather they muſt be kept very warm. While they are young, it will be proper to continue them in the bark-bed; but when they have obtained ſtrength, they may be placed in a dry ſtove, where they will thrive well, provided they are kept in a moderate temperature of heat, and have not too much water.

Theſe plants may alſo be propagated by cuttings, which ſhould be taken from the old plants two months before they are planted, during which time they ſhould be laid on the flues in the ſtove, that the part which joined to the old plant may be healed over before they are planted, otherwiſe they will rot. Theſe cuttings ſhould be planted in ſmall pots filled with light ſandy earth, and plunged into a moderate hot-bed of tanner's bark, obſerving to ſhade them in the heat of the day from the ſun, and refreſh them once in a week or ten days with water, but it muſt be given to them ſparingly each time. If the cuttings ſucceed, they will have taken root in about two months, when they ſhould have a larger ſhare of air to harden them by degrees to bear the ſun and air, and afterwards may be treated as the old plants.

The milky juice of theſe plants is very cauſtic, and reckoned poiſonous. In cutting off any of the branches of the plants, if the knife be not immediately cleaned, the juice will corrode it, and turn the blade almoſt black in a very little time, ſo as not to be cleaned off again; and if dropped on linen will cauſe it to waſh in holes, equal to aquafortis.

[PNEUMONANTHE. See *Gentiana*.

Panicle diffuſed, ſpikelets ovate five-flowered, glumes lanceolate ſomewhat ſilky free, ſtipules very ſhort blunt.

67. Poa cinerea. *Aſh-coloured Meadow-graſs.*

Villars dauph. 2. 126.

Stem-leaves ereſt involuted, ſpikelets three-flowered, ciliate at the baſe acute.

68. Poa brizaides. *Briza-like Meadow-graſs.*

Villars dauph. 2. 126.

Panicle contracted, ſpikelets round four flowered awnleſs.

69. Poa divaricata. *Straddling-ſpiked Meadow-graſs.*

Villars dauph. 2. 127.

Leaves plane ſtriated, ſpikelets ſix-flowered acuminate, paniele divaricate.

70. Poa montana. *Mountain Meadow-graſs.*

Allion. pedem. n. 2199. *Hall. helv. n.* 1468.

Gramen paniculatum anguſtifolium *montanum, panicula denſa*, locuſtis parvis muticis. *Scheuch. gram.* 186.

Panicle ſtrict, ſpikelets two-flowered, glumes villoſe at the baſe.

71. Poa ſabauda. *Savoy Meadow-graſs.*

Allion. pedem. n. 2200. *Hall. helv. n.* 1470.

Panicle looſe, ſpikelets two-flowered, flowers twice as long as the calyx very ſmooth.

DESCRIPTIONS, &c.

1. Root perennial, creeping. Culms from three to ſix feet high, upright, leafy, the thickneſs of a reed ſtraw, two-edged, ſtriated, ſmooth, the joints yellowiſh, the lower joints rooting all round. Leaves enſiform, from half an inch to almoſt an inch in breadth, acute, ſtraight, ſmooth on both ſides except that the keel and edges are rugged, very finely ſtriated, the baſe of the leaf on each ſide marked with a yellow triangular ſpot; ſheath ſmooth and ſtriated, the keel prominent, the membrane ſhort and obtuſe. Panicle very large, from ſix inches to a foot in length, very much branched: branches in half whorls, rugged; branchlets alternate, flexuoſe. Florets from five or ſix to eight, ſeldom more, ſubcylindric, remote, purple on the outſide, rugged. Calyx nearly equal, whitiſh, ſhining. Outer corolline glumes ſeven-nerved, inner emarginate. Styles from a little below the top of the germ. Nectary, a ſmall truncated ſcale at the baſe of it. Seed of a pale brown colour*.

Water Meadow-graſs is one of the largeſt of our Graſſes. In the fens of Cambridgeſhire, Lincolnſhire, &c. immenſe tracts that uſed to be overflowed and produce uſeleſs aquatic plants, and ſtill retain much moiſture, though drained by mills, are covered with

* Curtis, Smith.

this graſs, which not only affords rich paſturage in ſummer, but forms the chief part of their winter fodder.

It has a powerfully creeping root, and bears frequent mowing well. It is ſometimes cut thrice in one ſeaſon, near the Thames. It grows not only in very moiſt ground, but in the water itſelf; and with Cat's-tail, Burr-reed, &c. ſoon fills up ditches, and occaſions them to require frequent cleanſing. In this reſpect it is a formidable plant, even in ſlow rivers. In the Iſle of Ely they cleanſe theſe by an inſtrument called a Bear; which is an iron roller, with a number of pieces of iron, like ſmall ſpades, fixed in it; this is drawn up and down the river by horſes walking along the bank, and tears up the plants by the roots, which float, and are carried down the ſtream[f].

Poa aquatica is native of moſt parts of Europe, and flowers from july to ſeptember. Like ſeveral other ſpecies of Poa, it varies with viviparous flowers.

2. Root perennial, with ſimple, elongated, ſmooth fibres. Root-leaves very many, ſpreading, flat, widiſh, nerved, ſmoothiſh eſpecially underneath, bluntiſh at the end with a little dagger point, rugged at the edge; with ſhort erect compreſſed ſheaths, and a ſhort blunt ſtipule; ſtem-leaves two, very ſhort, with very long ſheaths, and lanceolate acute ſtipules. Culm a foot high, aſcending, having two joints, naked at top, round, purple, ſhining. Panicle ſhort, roundiſh or ovate, branches in pairs alternately ſubdivided, angular, ſmoothiſh, ſometimes rugged. Spikelets cordate or broad-ovate, compreſſed, ſhining with purple and bay-colour, three or four-flowered, in gardens ſix-flowered. Calycine glumes almoſt equal, ovate, acute, ſomewhat ſickle-ſhaped, obſoletely nerved, rugged on the edge. Florets ovate, ſharpiſh, ſcarioſe on the edge and commonly ſilky, briſtly at the baſe, but free and not connected by complicated hairs; the inner valves emarginate and ciliate[g].

Villars alſo remarks that the glumes of the corolla have ſome ciliæ at the edge; and that the culm is often compreſſed.

β. This ſpecies, in common with many alpine graſſes, which live almoſt conſtantly in a moiſt vapour, is frequently viviparous. Linnæus ſays, it is often found in this ſtate in the Lapland alps, and that it continues ſo in gardens; and that it is not the calyx or petals growing out into leaves; but the rudiment of the germ, like Lycopodium Selago, leafing, falling, and growing[h].

Dr. Smith's account is, that the glumes change into leaves, and at length the fructification into a bud.

Mr. Lightfoot informs us, that the ſpecimen he ſaw in Scotland was viviparous: the leaves ſmooth, compreſſed, and a little recurved; the ſtalk five inches high, ſlender, and purple; the panicle open and thinly ſet with flowers; the calyxes of a purple colour; and the germs viviparous.

Alpine Meadow-graſs grows wild in Lapland, Switzerland, Sileſia, Dauphiné, the highlands of Scotland, and Wales. It flowers in june and july.

3. Panicle ſmall, with the branches preſſed cloſe, two-flowered or three-flowered. Spikelets three-flowered or four-flowered. Calycine glumes mucronate. Glumes of the corolla acute, of a duſky violet colour, with a membranaceous white margin.

Native of the mountains of Switzerland, Bohemia and Sileſia[i].

4. Culm a foot high, aſcending, leafy. Upper leaves ſcarcely ſhorter than the culm, naked, linear, acute. Panicle elongated, narrowed; pedunckes ſhort, ſpreading, half whorled. Flowers numerous, minute. Calyxes ſmooth, pellucid, ovate, compreſſed, of the ſame ſize with the glumes of the corolla, two-flowered, more ſeldom three-flowered.

Native of the Eaſt Indies, whence it was ſent by Koenig[k].

5. Culm round, ſimple, upright, ſmooth, three feet high. Leaves enſiform, entire, ſtriated, ſlotted-ciliate, as is the whole of the ſheath, which is very long. Panicle a foot long. Pedunckes angular, ciliate-rugged at the angles. Pedicels very ſhort, preſſed cloſe. Calyxes having the keel very finely ſerrulate.—Native of Japan[l].

6. Root fibrous. Culms decumbent at the baſe and rooting, then erect, a foot and half high, ſimple, round, ſtriated, ſomewhat rugged, leafy, frequently purple. Leaves almoſt erect, flaccid, ſharpiſh, keeled, rugged, eſpecially underneath and round the edge. Sheaths almoſt the length of the leaves, ſomewhat compreſſed, ſtriated, a little rugged. Stipule lanceolate, acute. Panicle elongated, upright, very much branched, rugged; branches alternately decompounded, when in flower ſpreading horizontally. Spikelets ovate, generally three-flowered, purple and green. Calycine glumes rugged at the back, equal in length: outer linear-lanceolate, acuminate: inner dilated at the edge, three-nerved. Florets bluntiſh, five-nerved, ſcarioſe at the tip, ſomewhat ſilky at the edge and on the back: inner valves have a thickened, green and ſcarcely pubeſcent margin[m].

Culm from one to two feet high, creeping at bottom, whence this graſs becomes perennial. Spikelets ſmall, containing two or three, ſometimes four flowers. Glumes of the calyx unequal. If the glumes of the corolla are drawn out of them, a woolly ſubſtance is obſervable, as in P. pratenſis: theſe are nearly equal and pointed. Anthers yellow or purpliſh, finally becoming forked at each end. Germ very ſmall, ovate: ſtyles feathered almoſt to the bottom. Nectary, two little tender glumes, at the bottom of the germ. Seed oblong, pointed, having a woolly ſubſtance at bottom[n].

Dr. Withering remarks that the root is creeping; the whole plant rough; the height from one foot and a half to two feet or more; the panicle ſix or eight inches long, and three or four broad when fully expanded; the florets moſtly three or four in each ſpikelet, but generally three. Its creeping root, and the great roughneſs of the culm and leaves, ſufficiently diſtinguiſh this from P. pratenſis, to which it has otherwiſe ſome reſemblance.

Willdenow ſays it is ſufficiently diſtinguiſhed by its very branching diffuſed panicle, and eſpecially by the great length of the ligule or ſtipule, which character Curtis firſt pointed out. See *P. pratenſis*.

P. trivialis is certainly one of our beſt graſſes, both for hay and paſturage; indeed a good meadow can ſcarcely be formed without it. Its chief qualities are, that it produces a large quantity of ſweet tender leaves, preferred by cattle to moſt others, and convertible into exceeding fine hay. It is an early graſs, flowering about the beginning of june. It does not bear froſt ſo well, nor does it ſhoot ſo early in the ſpring as the Poa pratenſis; but when the weather becomes warm enough to make Graſſes in general ſhoot, this grows faſter, and produces a greater crop of bottom leaves than moſt others. Whilſt that is found chiefly in dry paſtures, this principally occurs in moiſt meadows, or on the edges of wet ditches: it loves moiſture, and a ſheltered ſituation. In very wet ground it grows very tall; but in poor dry paſtures it is diminutive[o].

So long ago as the year 1785, Mr. Boys of Betſhanger in Kent, a farmer of the higheſt reputation, raiſed at much expenſe, and ſeveral years attention, from twenty to thirty buſhel of the Poa trivialis, which he then offered for ſale at three ſhillings a pound. He ſays that it makes a very fine thick turf, and will produce a great quantity of very excellent graſs, from moiſt rich ſoils, and that horſes, cattle and ſheep, are all very fond of it: that the firſt ſeed he had was given him by William Boys, Eſq. of Sandwich, who collected it to the quantity of about an ounce. He uſed the ſtraw after the ſeed was thraſhed, inſtead of hay, for his riding horſes, and they preferred it to his beſt meadow hay. The ſeed being very ſmall, he thinks that ſeven pounds will ſow an acre; but to have the land covered thick the firſt year, a little more ſhould be ſown. Sifting the ſeed is a work of time, as it

[f] Curtis. [g] Smith. [h] Fl. ſuec. [i] Willdenow. [k] Retz. [l] Thunberg. [m] Smith. [n] Idem. [o] Curtis.

hangs

hangs together in lumps, and muſt be rubbed by hand though a ſieve fifteen wires to an inch[a].

It is no ſmall recommendation, ſays Mr. Curtis, to this Graſs, that it is a principal ingredient in that uncommonly productive meadow near Saliſbury, mentioned by Stillingfleet, and deſcribed in the firſt volume of the Memoirs of the Bath Agricultural Society, &c. See our article MEADOW.

Mr. Curtis had five turfs ſent him from this famous meadow, which he planted in his garden at Lambeth marſh. Poa trivialis appeared in all the ſix. Agroſtis paluſtris in three. Alopecurus pratenſis in two. Triticum repens in four. Avena elatior in one. Hence he concludes, that the extraordinary fertility of this meadow aroſe not from any new graſs peculiar to it, but from ſeveral unuſual circumſtances concurring and favouring in an uncommon degree the growth of certain well-known Graſſes, eſpecially Poa trivialis and Agroſtis paluſtris.

This long graſs was noticed long ſince by Merret and Ray, under the name of *Gramen caninum ſupinum longiſſimum*; and the place of growth aſſigned is Maddington, two miles from Saliſbury. Ray adds, that it is twenty-four feet long; that they fat hogs with it; and that it grows in ſome parts of Wales. The greateſt part of the meadow in which Mr. Swayne found this graſs is in the pariſh of Maddington; and that is divided from Orcheſton St. Mary only by a ſmall ſtream. The following account from that ingenious gentleman will at length clear up the obſcurities which have ſo long hung over this celebrated graſs.

A friend of Mr. Swaynes' in Somerſetſhire had been to ſee the Orcheſton graſs, and being on the ſpot at the time the meadow was mowing, was directed to the *real long graſs* by the farmer and labourers, and brought back with him living plants and ſpecimens of the flowers. The latter were the Alopecurus pratenſis of very large growth. Mr. Swayne carried home one of the plants and ſet it in his garden. The ſpring following it produced a very fine tuft of ſpikes of Alopecurus pratenſis. The year following, Mr. Swayne viſited Orcheſton the firſt week in june. The greateſt part of the meadow, or meadows, for there are ſeveral partitions, though the whole is not more than two or three acres, was then mown, and the graſs was lying in ſmall cocks. The ſtanding part, which was one corner, about a quarter of an acre had one uniform appearance, and preſented a thick and beautiful aſſemblage of the flowering panicles of what he took to be *Poa trivialis paluſtris* of Hudſon. It is not however the Poa paluſtris of Linneus, but only a trailing variety of Poa trivialis, taking root at the joints: as Dr. Withering determined from the ſpecimen ſent him by Mr. Swayne.

The graſs which had not been cut was lodged or lying on the ground, and had put forth roots at the knots, and began to be erect only at the laſt knot or two. Theſe meadows are mown twice, at the end of may or beginning of june, and at the end of july or beginning of auguſt.

Mr. Swayne remarks very judiciouſly that no graſſes but thoſe that flower early could be in bloom at the firſt mowing, and that whatever graſſes are in bloſſom at the laſt mowing muſt be of the late-flowering kinds. Mr. Davies ſays, in his Wiltſhire report, that Mr. Sole has determined the Orcheſton graſs to be the *Agroſtis ſtoloniſera*, and probably that graſs may be predominant, perhaps the only graſs in flower, at the time of the laſt mowing[b].

β. Dr. Smith regards the *Poa fetacea* of Hudſon's firſt edition as a variety of this; for it cannot be referred to P. pratenſis on account of its lanceolate acute ſtipule. The lower leaves are involute-ſetaceous.

7. Panicle oblong, crowded, ſo as to ſeem almoſt imbricate, with four-flowered florets, when ripe often villoſe, wandering, cohering. Anthers yellow[c]. Linneus ſpeaks of it as growing every where with the preceding in Sweden and Lapland. Dr. Smith regards it as a variety of P. pratenſis; which ſee.—For *P. anguſtifolia* of Hudſon, &c. ſee *P. nemoralis*, *n.* 50.—and *P. capillaris*, *n.* 34.

8. Culm round, ſmooth, ſtraight, a foot high and more. Leaves few, in long ſheaths. Panicle naked, looſe: pedunckes erect, angular, ſolitary or in pairs, divaricate. Spikelets ſubſeſſile, lateral and terminating, compreſſed. Valves of the calyx almoſt equal, keeled, of a reddiſh bay colour, with pellucid margins. Corollas keeled, equal in length, of an elegant bay colour, large, one wider than the other. Filaments very ſhort: anthers longer, purple, incloſed. Styles alſo very ſhort[d].

Native of the mountains of France, Italy and Switzerland. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in april and may[e].

9. Root perennial, creeping by runners, eaſily penetrating into the earth and crevices of walls. Culms upright, ſmooth, ſcarce perceptibly ſtriated, a foot or eighteen inches in height. Leaves ſmooth, of a dark green colour, ſometimes glaucous or blueiſh, keeled, bluntiſh, ſpreading. Sheaths the length of the leaves, ſtriated, ſmooth. Stipules ſhort, blunt. Panicle as in trivialis, but leſs rugged. Spikelets ovate, four-flowered, often five-flowered, ſometimes only two-flowered, flattened on each ſide, green or ſometimes purple. Calycine glumes ſharp, rugged on the back, a little unequal, three-nerved. Florets bluntiſh, five-nerved, ſcariole at the tip, rugged on the back, connected at the baſe by numerous very long complicated villoſe hairs; the inner valves ſomewhat pubeſcent at the edge. Filaments longer than the glumes: anthers forked at each end. Styles branched to the bottom. Nectary, two little glumes at the baſe of the germ. Seed angular, pointed[f].

Dr. Withering remarks, *that it* is from one to two feet high; that the leaves, though much leſs rough than in *P. trivialis*, are not always ſmooth; that the panicle is heavy when in ſeed, not greatly diverging, from two to four inches in length, and more than half as broad.

The late Mr. Curtis, whoſe attention to Graſſes is well known, firſt accurately diſtinguiſhed *P. trivialis* and *pratenſis*, which are ſo alike in their general appearance, as hardly to be diſtinguiſhed without nice examination. The *pratenſis* however is in every part ſmooth; whilſt in *trivialis* the ſtalk, leaves with their ſheaths, and the branches of the panicle, all feel rough, if the plant be drawn downward betwixt the thumb and finger: in the *trivialis* the ſheath of the leaf is flatter and more deeply fluted: the root of the *trivialis* is ſimply fibrous; that of the *pratenſis* is creeping, and ſends out many white ſhoots; but what diſtinguiſhes them moſt fully is, that the membrane at the bottom of the leaf where the ſheath begins, (ligula ſ. ſtipula) in the *pratenſis* is very ſhort and blunt, in the *trivialis* long and pointed: this diſtinction is obvious to the moſt common obſerver, and never fails, let the graſs vary ever ſo much in ſize, &c. Theſe two graſſes differ alſo in the ſize of the ſpikelets, and the number of flowers contained in each; in the *trivialis* they are biflorous or triflorous, in the *pratenſis* moſt commonly *quinqueflorous*. The *pratenſis* grows generally on walls, or on dry banks, but often in meadows: the *trivialis* is ſcarce ever found on walls, ſeldom on dry banks, but moſt frequently in moiſt meadows or by the ſides of ditches: the former flowers about the third week in may, the latter the firſt week in june; after the *pratenſis* has once flowered, it ſhows no diſpoſition to do ſo again; whilſt the *trivialis* is found in bloom, though not generally, during the whole of the ſummer. Laſtly, there is a firmneſs in the ſtalk of the *pratenſis* not perceivable in the *trivialis*. As to the pubeſcence, or filamentoſe appearance, which ſeems to connect the florets and calyx together, and adheres to the ſeeds ſo as to cauſe them to hang together as if there were cobwebs among them, it takes place nearly in an equal degree in both ſpecies[g].

The foliage of Poa pratenſis begins to ſhoot, and to

[a] Young's annals, 5. 415. [b] Wither. arr. 144. [c] Linn. ſuec. [d] Gerard prov. [e] Hort. kew. [f] Curtis, Smith. [g] Flora lond.

aſſume

aſſume a beautiful verdure very early in the ſpring, but its flowering ſtems are not produced ſo ſoon, by a week at leaſt, as thoſe of *Alopecurus pratenſis* or Meadow Foxtail-graſs. Where early paſturage is deſired, it cannot better be obtained than by a combination of theſe two with *Anthoxanthum odoratum* or ſweet-ſcented Vernal-graſs. If crop be an object, the Foxtail ſhould predominate.

This graſs preferring a dry ſituation, keeps its verdure in a continued drought better than moſt others: but it has a root like Quich or Couch-graſs, (Triticum repens) and ought therefore to be cautiouſly introduced, where the meadow is not intended to be permanent. From its not throwing up any ſtems or bents but once in the ſeaſon, together with its hardineſs and verdure, it ſeems to be a good graſs for lawns.

In dry ſoils, the crop from this graſs yearly diminiſhes in quantity, ſo as at laſt to be very trifling; in moiſt meadows this effect has not been ſo obſervable. Upon the whole, this graſs has rather ſunk than riſen in Mr. Curtis's eſtimation [k].

Dr. Withering relates that this graſs conſtitutes a conſiderable part of the herbage on the rich meadows in the flat parts of Somerſetſhire.

Mr. Swayne obſerves, that in meadows which have been flooded the whole winter, it flouriſhes ſo as nearly to exclude every other graſs.

β. Dr. Smith conſiders *Poa anguſtifolia* of Linneus as a variety of this graſs; and informs us that it differs from it in having the lower leaves very narrow, and ſtiffiſh, the panicle ſmaller, and the lower ſheaths ſomewhat rugged.

Dr. Withering makes *P. fetacea* of Hudſon a variety of this ſpecies. According to Dr. Smith, it is a variety of *P. trivialis*.]

Mr. Miller celebrates the perennial Meadow-graſſes as the beſt ſpecies for paſtures, and ſuggeſts that if the ſeeds of theſe were carefully collected, and ſown ſeparately without any other mixture of Graſs-ſeeds, they would not only afford a greater quantity of feed on the ſame ſpace of land, but the graſs would alſo be better, the hay ſweeter, and the verdure more laſting than of any other ſorts.

[10. Leaves convoluted, ſtriated, erect, ſmooth, a little longer than the culm. Sheaths bearded at the opening. Culm ſimple, erect, a foot high. Panicle rod-like, a ſpan long. Peduncles and pedicels capillary, flexuoſe. Calyxes four-flowered and five-flowered, acute, ſmooth, duſky-ruſt-colour. It has the appearance of *P. Eragroſtis*, but the ſpikelets are ſhorter and few-flowered.—Native of Japan [l].

11. A foot high and more. Culms grooved, ſmooth, brown at the knots. Leaves dark green, ſmooth, ciliate about the ſheath, two or three lines wide. The leaf almoſt under the panicle, equals or exceeds the whole panicle; which has three or four branches from the ſame point, ſeldom one only. Branches flexuoſe, the firſt branched again. They all put forth diſtich ovate-oblong ſpikelets, diſpoſed in a ſort of thin ſpike, for the moſt part alternate, peduncled. Peduncles moſtly one-flowered, ſometimes two-flowered. Spikelets ſometimes three-flowered, commonly four-flowered, ſometimes five-flowered. Calycine valves acute, with a prominent greeniſh nerve. Corolline glumes ovate, having alſo a nerve. It is an annual graſs, native of Italy, where it was found by Bellardi [m].

12. Panicle almoſt half a foot long, with capillaceous branches, preſſed cloſe and ſubdivided. Spikelets ſmall, green. Corollas ſmooth, having five raiſed nerves on each valve. Native of North America [n].

13. Root perennial. Culms many, upright, from two to three feet, and often a little more in height, round, ſmooth, blueiſh green; having four purpliſh joints. Leaves flat, mucronate, bright or reddiſh green, ſmooth above but ſomewhat rugged underneath, with a whitiſh nerve. Ligule or ſtipule jagged, two lines in length. Sheaths ſmooth, ſtriated, ſomewhat rugged when drawn backwards. Panicle green and white; branches two from the ſame point, conſiſting of cloſely crowded branchlets, eſpecially towards the top. Spikelets ſmall, ovate-oblong, compreſſed, from four to ſix-flowered, whitiſh green, mixed ſometimes with a little purple. Glumes of the calyx narrow, lanceolate, keeled, mucronate, the larger little more than a line and half, the ſmaller more than a line in length. Glumes of the corolla lanceolate, narrow, ending in a very acute point, two lines in length.

This ſpecies differs evidently from all the other ſpecies, except the *alpina*, and from that it may be diſtinguiſhed, by its longer culm, much wider leaves, ſmaller ſpikelets, and by its narrow very acute glumes [o].

Native of Germany. It was firſt obſerved by Pollich in the Palatinate, flowering in june and july. The *ſylvatica* of Kroecker ſeems to be the ſame with this; but whether that of Villars be ſo is very doubtful.

14. Height four feet. Leaves wide. Habit like that of the preceding, but ſufficiently diſtinct. Culm two-edged. Spikelets bright green, much ſmaller than the preceding, with the florets acuminate.

Native of the mountains of Sileſia, and of the marſhes of Hanover and Magdebourg [p].

15. This is a middle ſpecies between the *trinervata* and *judaica*: it differs from the former, to which it approaches the neareſt, in having ſhorter broader leaves, a longer ligule, a ſhorter panicle of a red colour and leſs divaricate, the ſpikelets more crowded and rugged, the outer valve of the corolla five-nerved. It is a perennial graſs, native of the lower Heſſe [q].

16. Native of New Zealand [r].

17. Root annual, remarkably full of fibres. Culms numerous, forming a thick tuft, ſemiprocumbent, but in meadows among other plants nearly upright, ſlender, leafy, ſmooth and even, at the baſe rooting and branched, about half a foot high, or varying in different ſituations from leſs than three inches to near a foot. Leaves very numerous, linear, bluntiſh, flat or ſometimes tranſverſely wrinkled, flaccid, ſmooth, bright green, rugged or finely ſerrate on the edge. Sheaths elongated, flat, ſmooth, ſtriated, paliſh. Stipule ſhort, ſubdeltoid, eroſe. Panicle triangular, flattiſh, erect, ſmooth: branches or peduncles at the bottom generally in pairs, one ſhorter than the other, in the middle often in threes, and at top ſingle: it is thinly ſet, near two inches long and almoſt as broad. Spikelets ovate-oblong, flattiſh and ſharp on both ſides, three, four, or ſometimes five-flowered, ſhining, green and white variegated, ſmooth. Calycine glumes lanceolate acute, keeled, unequal. Florets rather remote, ovate-lanceolate, blunt, five-nerved, membranaceous at the edge, ſomewhat ſilky at the back, but entirely free at the baſe, not connected by hairs. Styles exceedingly branched and pellucid. Seed ovate, covered by the corolla, which adheres to it, and ſlightly villoſe at bottom [s].

Poa annua is diſtinguiſhed from *P. trivialis* by its general habit, its ſpreading panicle, its reclining culms, its ſmoothneſs and greater ſoftneſs and delicacy: from *P. pratenſis* by having the branches or peduncles in pairs, its panicle more thinly ſet, and its ſpikelets larger: from both, by its inferior ſize, compreſſed culms, annual root, property of throwing out new ſhoots, and having the florets and ſeeds ſeparate, not hanging together by cobweb-like hairs.

If *Gramen* be ſo named, ſays Ray, *a gradiendo* or *progrediendo*, no ſpecies better merits the name than Annual Meadow-graſs. Mr. Curtis, to whoſe accounts of Graſſes it is difficult to add any thing new, remarks, that it differs very conſiderably from all other annual graſſes, in continually throwing out new ſhoots, and producing new flowers and ſeeds, inſomuch that if the ground be moiſt, a ſingle plant will grow in this manner throughout the year, ſo that we generally find on the ſame plant young ſhoots and ripe ſeeds. It imitates therefore the tropical plants in this circumſtance, and is perhaps the only vegetable we have that does ſo.

[k] Pract. obſ. ed. 3. p. 12, &c. [l] Thunberg. [m] Allioni. [n] Willdenow. [o] Pollich. [p] Willdenow. [q] Idem. [r] Forſter. [s] Curtis, Smith.

No

No graſs is better entitled to the accurate Ray's epithet of *vulgatiſſimum*, for it is common to every quarter of the globe, and occurs almoſt every where in meadows, gardens, by the ſides of paths, and on walls; flowering all the ſummer, and even in the winter, if the weather be mild. In open fields the panicle frequently acquires a reddiſh tinge.

It appears to be one of the firſt general coverings which nature has provided for earth made bare from any cauſe; hence it is frequent on the edges of paths, where its ſeeds being ſcattered quickly vegetate, and the plants not being overpowered by more luxuriant herbage, continue to flouriſh; this gave occaſion to Mr. Stillingfleet to ſuppoſe that this graſs thrived the more for being trodden on, but this ſuppoſition is void of foundation.

In walks, pavements and pitching it is one of our moſt troubleſome weeds; in ſuch ſituations the moſt expeditious way of deſtroying it, would be by pouring boiling water on it.

Mr. Stillingfleet ſays that it makes the fineſt of turfs; that it is called in ſome parts Suffolk Graſs, there being whole fields of it in High Suffolk, without any mixture of other graſſes, and that it is likely to be the beſt graſs for the dairy.

Its foliage is tender and grateful to cattle, but it never acquires any great height: it is alſo liable to be killed by winter's froſt and ſummer's drought.

May or june is the beſt time to gather the ſeed in greateſt abundance; but as a ſingle tuft of this graſs may be divided into a vaſt number of plants, and as they grow with wonderful facility, an experiment, on a ſmall ſcale at leaſt, might be tried with it by tranſplanting it in moiſt weather [1].

This ſpecies becomes viviparous in alpine ſituations [2].

18. Native of Virginia [3].

19. Root annual, in bundles of fibres. Culm ſimple, upright, round, ſmooth, a ſpan in height. Leaves narrow, linear, attenuated at the tip, ſetaceous, convoluted, entire, ſmooth, longer than the culm. Joints bearded. Peduncles bifid or branched, with alternate, flexuoſe, ſmooth pedicels. Spikelets five, ſix or ſeven-flowered, oblong, often ferruginous, ſmooth, ſerrate from patulous florets. Native of Japan [4].

20. Height fourteen and ſixteen inches. Leaves on the culm three or four inches long, ending in a ſharp point, ſmooth except at the edges, where they feel rough if drawn between the finger and thumb. Panicle very thin, looſe and ſcattered, from a hand to half a foot in length. Branchlets or peduncles very ſlender, moſtly ſingle and at unequal diſtances, except the loweſt, which come out every way in a ſort of whorl. Spikelets ſmall and delicate, of various ſizes: the loweſt on ſhorter peduncles, only a line in length or ſhorter, three-flowered; others a line and half in length and four-flowered; others two lines in length, having five, ſix or ſeven florets, placed alternately. Calycine glumes narrow, acuminate, unequal, the larger ſcarcely half a line in length. The lower glume of the corolla a line and half long, the upper one a little ſhorter. The lower branchlets of the panicle are villoſe with longiſh hairs at the baſe; and the other branchlets (or peduncles) up to the middle of the panicle have a very fine ſlender hair or two, about two lines in length at their baſes. Native of Italy about Bologna [5].

21. Root perennial, creeping. Culm from a foot to two feet in height, ſometimes but ſeldom three feet, at firſt decumbent, then erect, weak, round, rooting at the four or five lower joints by white capillary fibres, between the joints involved in green white or brownish ſheaths, putting out at almoſt every rooting joint a lateral ſhoot, rendering the culm as it were dichotomous; the joints are very cloſe near the baſe, but very remote in the upper part of the culm. Leaves ſcarcely two lines wide, acuminate. Ligule or ſtipule ſubdiaphanous. Panicle half a foot or more in length, pyramidal, the lower branches being very long and decreaſing gradually till the uppermoſt are very ſhort: pedicels ſlender, unequal, alternate, ſeveral together from the ſame point, branched, criſped as it were with various flexures. Spikelets variegated with green and white, ovate, compreſſed, acuminate. Calyx two or three-flowered; one glume narrower, both blackiſh on the outſide, acuminate. Glumes of the corolla narrower, green, acuminate, browniſh at the tip, covered with a very fine pubeſcence or villus at the baſe [6].

Krocker could not obſerve that the ſpikelets were pubeſcent; he has ſeen them with four flowers. He remarks that the rachis at the riſe of the pedicels is divided by little white knobs, as in moſt of the other ſpecies.

He diſtinguiſhes it from *P. trivialis* by its creeping, dichotomous culm; its creeping root; its thinner, longer and more diffuſed panicle; and its wider, longer, rugged leaves: from *anguſtifolia* alſo by its culm and leaves; its longer, wider panicle, and larger ſpikelets. It is known, ſays Seguier, when the rice-fields are hoed, during its tender ſtate, by its glaucous leaves; when farther advanced, by the ſpinules of the leaves [7].

Haller informs us, that Bauhin's name does not appertain to this ſpecies, but yet that Moriſon's figure does repreſent it.

Native of Denmark, Switzerland, Italy, and Germany.

22. Culm one or two feet high, ſuberect, very ſlender, ſtrict, round, ſmooth, jointed below. Leaves ſhort, linear, acute, concave, ſpreading, hairy or ſomewhat hirſute; the hairineſs thin and clammy. Sheaths hirſute. Panicle two inches long, ſomewhat hirſute: branches alternate, diſtant, ſimple, few-flowered. Spikelets diſtinct, three to ſix on a branchlet, purple, pedicelled. Calycine valves acute, keeled, minute. Corolline glumes a little larger, ovate, acute, keeled, flatted a little; the inner ciliate, when examined by a magnifier; with that advantage, the keel alſo appears ſerrulate. Filaments very ſhort. Anthers dark-purple. Stigmas hairy, whitiſh. Seed roundiſh, very minute.—It is diſtinct from *P. piloſa* in not having the loweſt branchlets of the panicle whorled and hairy: —from *P. amabilis* in having fewer florets, not linear: —from *P. Eragroſtis* in the rigidity of the panicle, the diſtance and clammineſs of the branchlets, &c.—from *P. capillaris* as in the preceding, and alſo in having an upright ſimple culm.

It is an annual graſs, native of Jamaica, in dry ſand.

23. Culm a fathom high and more, upright. Branches ſubdivided, round, ſtriated, ſmooth. Joints knobbed, leafy, proliferous as it were with the origins of a younger plant. Leaves in bundles, linear, ſetaceous, commonly convoluted, ſheathing, erect, even. Panicles a ſpan and more in length, branched, erect: branchlets ſubdivided, capillary, ſtrict, flexuoſe. Spikelets pedicelled, lanceolate, compreſſed. Calycine valves equal. Corolline valves ovate, acuminate, keeled. Filaments two or three. Anthers pale. Stigmas villoſe.

Native of the Caribee iſlands; St. Lucia, Guadeloupe [8].

24. This is very nearly allied to the next ſpecies, with purple flowers, and three-nerved glumes, the lower of which gradually fall. Native of the Eaſt Indies [9].

25. This is an annual graſs. The outer glumes keeled, hyaline, with green nerves on both ſides, by which it is eaſily diſtinguiſhed. Flowers ovate, ſharpiſh, ſix to nine-flowered without a ſcarioſe margin. Panicle waved [10].

Though annual, this graſs throws out ſeveral inclined culms on a fibrous root, thus forming a dark-green turf. They are from ſix to ten inches in height, and divide by furniſhing ſeveral lateral branches, which bear panicles at their lower part. Leaves open, flat, dark green, having a pencil of hairs at their baſe on each ſide. Terminating panicle oval, upright, two or

[1] Curtis. [2] Davies in Smith. angl. [3] Gronovius. [4] Thunb. [5] Scheuchzer. [6] Krocker. [7] Veron. 1. 351. [8] Linn. ſpec. [9] Swartz. [10] Lin. ſpec. [11] Linn. mant.

three inches long, compoſed of a great number of filiform ſtraight branches, and an infinity of ſpikelets, which are linear, reddiſh, very narrow, almoſt cylindrical, each compoſed of from eight to ten flowers. Glumes ſmooth, reddiſh or brown, with a whitiſh margin.

When the ſpikelets of the upper panicle are ripe, the ſeeds fall immediately, and ſucceſſively thoſe of the middle and baſe of the culm. This quick falling of the ſeeds, is the reaſon why we may often obſerve the young flowers withering at the baſe, whilſt thoſe in the middle are in the ſtate of full expanſion, and the upper ones falling preſent ripe ſeeds, of an uncommon fineneſs, though accompanied by the inner glume, and often by both.

In Dauphiné the panicle is not ſpreading, the peduncles are ſcarcely flexuoſe, and the glumes have not any ſenſible nerves. Theſe characters are found in *Briza Eragroſtis*, which a little reſembles this: but the wide flatted ſpikelets of that are three times as big, and three times leſs in number; beſides the three nerves are ſo ſtrongly marked, that the middle one forms a keel, and renders the ſpikelets diſtich and flatted, whilſt the two lateral nerves leave between them and it a curved deep ſpace. The ſpikelets of *P. Eragroſtis* on the contrary are almoſt cylindrical, becauſe they are very narrow, and have no nerve[a].

Lamarck and Cavanilles inſiſt that *Poa* and *Briza Eragroſtis* are one and the ſame plant.

According to Deſfontaines, the culms are ſlender, procumbent at the baſe, often knee-jointed. Leaves wide, ſomewhat villoſe. Sheath crowned with little briſtles. Panicle elongated, narrow. Pedunckes capillary, flexuoſe. Spikelets compreſſed, linear-ſubulate, duſky purple, cloſely imbricate in a double row. Outer calyx from eight to fifteen-flowered. Outer glumes of the calyxes keeled, bluntiſh.

Native of Switzerland, Dauphiné, Spain, Italy, on walls; alſo of Barbary and Siberia.—Introduced in 1776, by Mr. Thouin[b].

26. This graſs forms a turf. Root-leaves two inches long, linear, ſmooth; culm-leaves only half an inch in length. Ligule large, truncate. Culm quite ſimple. Panicle ſqueezed cloſe. Corollas nerveleſs, acute, pubeſcent at the baſe, of a duſky violet colour, with a membranaceous margin.

Native of Baden on the rocks by the hot baths in lower Auſtria and Mansfield. Perennial[c].

27. This is an extremely handſome Graſs. Culms of the ſame ſize with thoſe of Wheat, ſimple. Raceme ſimple, a foot long, compoſed of alternate, quite ſimple, equal pedunckes, longitudinally pinnate on both ſides from the baſe to the tip. Flowers ſeſſile, approximating, compreſſed, equal, flatted as in Cyperus. Glumes compreſſed, keeled, ſharpiſh, ovate[d].

Culms two feet high, ſolitary, round, erect, with diſtich reflex leaves at the baſe, and two or three convoluted leaves on the culm. Panicle often longer than the culm, remarkable for its blood-red colour in flowering-time. Pedunckes whorled in threes, horizontal, gradually ſhorter upwards. Spikelets crowded, numerous, many or about ten-flowered. Calycine valves unequal. Corolline valves acute, keeled[e].

Native of Egypt and the Eaſt Indies.

28. Spikelets ſhort, like thoſe of Briza; but the valves acute and keeled. Calyx of the lower flowers of the panicle four-valved, of the upper two-valved. The lower flowers four-flowered, the upper eight, ten or twelve-flowered. This is a middle graſs between Poa, Briza and Uniola. It was found in the Eaſt Indies by Koenig[f].

29. 30. Theſe were found at the Cape of Good Hope by Thunberg.

31. Branches of the panicle in whorls, branched, much longer than in Poa (Briza) Eragroſtis. Spikelets very numerous and narrow: the calyx and lower glumes often falling. Culms proſtrate and more than a foot in length. This graſs reſembles Poa (Briza) Eragroſtis, in every thing except the panicle and ſpikelets. It is annual, and native of Spain, flowering there in july[g].

32. Culm baked at top, firm. Leaves acute. Sheath without any membranaceous crown. Flowers looſely panicled. Pedunckes long, capillary, angular, flexuoſe, rough, branched, ſolitary in twos or threes. Rachis flexuoſe, angular, rough. Spikelets pedicelled, blunt, greeniſh-brown. Outer calyx eight to ten-flowered; glumes unequal, ſharpiſh. The outer glume of the inner calyxes keeled, larger, incloſing the other. Anthers very ſmall. Seed very ſmall, oblong. It is allied to P. verticillata, but the ſpikelets are twice as wide, the culms are erect, and the ſheaths have no ligule or ſtipule. Root perennial.

Native of Barbary, near La Calle[h].

33. Root annual. Culm ſlender, a little compreſſed, branched, procumbent at bottom, bent in at the knots. Leaves ſublinear, acuminate, ſheathing, roughiſh at the edges with very minute toothlets. Panicle on capillary compreſſed ſpreading rachiſes. Spikelets oblong, blunt, from four to ſix-flowered. Calycine valves lanceolate, acuminate, erect, concave, compreſſed, whitiſh with a green back, appearing obſolerely toothletted when magnified; one longer than the other. Corolline valves like the others. Florets alternate on the rachis, which is flexuoſe arch-wiſe. Stigmas purple. The whole plant is very ſmooth[i].

It is from the grain of this plant that the common bread in Abyſſinia is prepared; that made from wheat being uſed only by the ſuperior ranks. The flour of the beſt kind of Teff is, according to Mr. Bruce, as white as that of wheat, and is very light and eaſily digeſted; other kinds are of a browner and coarſer quality: that which grows on light ground is accounted the beſt. The manner of making the Teff bread is by taking a broad earthen jar, and having made the flour into a lump with water, they put it into the jar, and let it ſtand at ſome diſtance from the fire till it begins to ferment or turn ſour, and then bake it into cakes of a circular form, and about two feet in diameter: it is of a ſpongy ſoft quality, and a hot diſagreeable ſouriſh taſte. From the ſame bread, by being well toaſted, and infuſed in water for ſome days, is prepared the common beer of that country, which is called by the name of bouza[k].

Cultivated in Abyſſinia. Introduced here in 1775, by James Bruce, Eſq. It flowers in auguſt and ſeptember[l].

34. Culm from ſix inches to two feet in length, decumbent at the baſe, proſtrate, filiform. Leaves long, very narrow, erect, with the ſheaths ſomewhat hairy. Panicle with very long diffuſed branches. Florets diſtant, pedunceled, patulous, minute. Calyxes four or five-flowered: glumes awnleſs, acute. Corolline glumes more diſtant, oblong, acute. Anthers purple. Stigmas villoſe, purpliſh. Seed roundiſh, ſhining. Common in the Weſt Indies[m], Virginia and Canada. Introduced, according to the Kew catalogue, by Monſ. Thouin, in 1781.

The graſs in the meadows round Montreal, ſays Kalm, is chiefly the *Poa capillaris*. It is very ſlender, grows very cloſe, and ſucceeds even on the drieſt hills. It is however not rich in foliage, and the ſlender ſtalk is chiefly uſeful for hay. Many ſorts of graſs in Sweden make infinitely finer meadows than this.

Kalm informs us, in another paſſage[n], that the high meadows in Canada are excellent, and far preferable to thoſe round Philadelphia. The farther he advanced northward, the finer he found them, and the turf upon them better and cloſer. Almoſt all the crop was *Poa anguſtifolia*, or narrow-leaved Meadow-graſs and *Trifolium repens*, white or Dutch Clover. The ſpikelets of the former contained three or four flowers, ſo exceedingly ſmall, that the plant might eaſily be taken for an *Agroſtis*, and the ſeeds have ſmall downy hairs at the bottom, as in *trivialis* and *pratenſis*. It is pretty tall, but has very thin ſtalks; the ground however is

quite

quite covered with the Clover, and both together make very fine meadows.

35. Culm sheathed with leaves, round, striated, smooth, upright, two feet high and more. Branches alternate, simple. Leaves ensiform, narrow, striated, shorter than the culm, a span in length. Sheaths long, without any hairs. Panicle from erect spreading, very much branched, a foot long. Rachis angular, striated, smooth. Pedicels capillary, branched, flexuose. Spikelets erect, from five to nine-flowered, subpellucid.—It differs from *P. capillaris* in the number of flowers, all smooth, in the smoothness of the leaves, not hairy even at the base, and in the uprightness and superior height of the culm. Native of Japan, in Kosido and near Nagasaki[1].

36. Flowers by no means sessile, but pedicelled, and more remote and elongated than in the *chinensis*. Calyx four-flowered, shorter than the flowers, with the keel ciliate. Rachis rough. Leaves and sheaths naked[2]. Native of the East Indies, in sandy ground.

37. Leaves hairy; especially at the sheaths. Rachis not rough. Flowers pedicelled, not sessile, almost pressed close to the rachis and imbricate. It varies with two, three and four-flowered calyxes, no less than in height[3].

Culm two feet high, slender, round, almost upright. Leaves lanceolate, smooth. Panicle oblong, with the branches quite simple and spreading. Calyxes six-flowered. Florets imbricate[4]. Native of India, China and Cochinchina.

38. Culms a foot and half high, ascending, even, the thickness of a pigeon's quill, with very swelling joints, often three in number. Leaves somewhat rugged, even underneath, longer than the internodes, rugged on the edge, and having a few erect hairs towards the base. Sheaths even. No ligule or stipule at the opening. Panicle spreading like that of *Milium effusum*. Peduncles, when the flowering is part contracted into a raceme. Spikelets lanceolate, twelve or fourteen-flowered. Florets diaphanous, with a dot (from an anther) within of a dusky colour, and a green streak on each side. Corolline glumes ovate, sharpish, even, much resembling those of the calyx. Native of Malabar[5].

36. Culms from two to three feet high, round, erect, simple. Leaves narrow, short. Branches of the panicle in half whorls. Spikelets reddish or whitish green, linear, containing about ten florets. The outer valve of the corolla is bent down at the tip and has the margins reverfed.

Native of the East Indies. Koenig fent it from Tranquebar, where it is frequent on the borders of fields, and in Paddy-grounds that are not over wet[6].

40. Root annual. Culms even, proftrate, branched at bottom. Leaves even, with a rugged edge, and a hairy opening. Panicle fpreading very much. Flowers oblong, blunt, purplifh, with a green line on each fide; the margin appearing to be ciliate, when examined with a magnifier[7].

It is obferved by Retzius, that not only the leaves are hairy at the throat or opening, but that the whole panicle at the bafe of the peduncles has bundles of long white hairs, from three to fixteen in number.

Native of the Eaft Indies. Introduced in 1781, by Monf. Thouin. It flowers in july and auguft[8].

41. Root perennial, creeping. Culms decumbent at the bafe, from fix inches to a foot in height, very fmooth, round, ftriated, leafy. Leaves rolled in, fo as to refemble thofe of rufhes, glaucous, acute, with long fheaths. Stipule blunt, but fometimes fharpifh. Panicle upright, ftrict, or little fpreading; branches commonly in pairs, angular, rugged, a little flexuofe, racemed, fpreading when in flower, and afterwards erect, fometimes divaricating, as in *P. diffans*, to which it is very nearly allied; differing however in having the root creeping, the florets longer, fharper, and by no means retufe. Spikelets linear, fmooth, purplifh, five-flowered or thereabouts (three to feven or eight. *Hudf.*). Calycine glumes unequal, ovate, fharpifh, keeled; outer three-nerved. Florets fomewhat remote, oblong, fubcylindrical, bluntifh but not retufe, fcarce apparently five-nerved, lefs fcarioſe at the tip; inner glumes rugged at the edge, emarginate at the tip[9]. Inner valve of the corolla very minutely ferrulated.

Mr. Lightfoot remarks, that it is nearly related to *Feſtuca* (*Poa*) *fluitans*, and that perhaps the fea-water may occafion the difference. But this opinion is not probable; for the outer and larger valve of the corolla in this plant wants the ribs, which are fo ſtrongly marked in *F. fluitans*; the inner valve wants the open cleft at the end; and *F. fluitans*, examined whilſt growing in the falt marſhes at Lymington, was found to vary but little from that growing in inland places[10].

It is obferved by Willdenow, that in the wild plant, the panicle is fqueezed clofe, narrow, and directed one way, with fpikelets having from four to eight flowers; but in a garden, the panicle is divaricate, and the fpikelets have from five to twelve flowers.

Native of Denmark, Britain, Germany and France, on fandy coafts, and in falt marſhes. About Yarmouth; between Briſtol and the Hot-wells; near the canal from Droitwich to the Severn, meadows near Wifbeech, &c. &c. In Scotland, in the iſland of Oranſa, in Skye, at Loch-Broom in Roſſſhire, &c. It flowers in july.

42. Root fibrous, forming a turf. Herb glaucous. Culms feveral, more or leſs proſtrate, about a ſpan long, leafy, ſmooth, bent at the joints. Leaves widiſh, acute, flat, nerved, ſomewhat rugged, with very long ſheaths. Stipule ſharpiſh, torn. Panicle rigid, leaning to one ſide (ſecunda,) ſemicylindrical, its main and partial ſtalks (rachis ramuliquæ) nearly round, rugged. Spikelets two-ranked (diſtichæ,) ſeſſile, lanceolate, four or five-flowered, glaucous, ſmooth. Calyx-valves blunt, very unequal, keeled; the outermoſt having five ribs. Florets bluntiſh, five-nerved, membranous and torn at their apex; their inner valves ciliated[11].

Dr. Smith affirms that this graſs has an annual root. On the contrary, Mr. Curtis ſays, "from the ſame root, which is clearly *perennial*, we have, as in *Poa annua*, young ſhoots and ripe ſeeds. However *P. procumbens* ſeems to be no more perennial than that.

We may add, from Mr. Curtis's deſcription, that the ſtems are from four to ſix inches or more in length, having two or three joints, flattened towards the panicle. Leaves ſhort, two lines broad, the edges very minutely ferrulate. Stipule ſhort, embracing, ſomewhat pointed, white. Sheath glofly on the inſide; the outer ſurface the ſame as that of the leaves. Panicle about two inches long, ſomewhat ovate, now and then bent a little backwards: the branches in pairs, unequal, the outer one largeſt: in the lower branches a ſingle ſpikelet is moſt commonly placed in the middle betwixt them; in impoveriſhed ſpecimens, a ſpikelet often holds the place of a branch. Common pedunceles round, naked, crooked, marked at the baſe on the upper ſide with a glandular ſubſtance. Rachis round, ſmooth, with two grooves on the inſide. Spikelets in the larger branches about ſix, in the ſmaller four, ſomewhat linear, roundiſh, ſlightly flattened, equidiſtant. Florets obtuſe, hairy at the baſe. Calyx-valves green edged with white, ſomewhat blunt. Corolla-valves almoſt equal; the outer rather larger and five-ribbed; the inner narrower and two-ribbed; the ribs edged with hairs. Germ obovate, pale green. Styles ſpreading and ramified quite to the baſe. Nectary, two ſmall tranſparent glumes, tumid and fleſhy at the baſe, a little longer than the germ. Seed oblong, ſmooth, incloſed in the glumes.

In general habit it comes near to *P. annua*; it bears an affinity alſo to *P. rigida*; but from thoſe and all the other ſpecies it is ſufficiently diſtinct. The ſtalks are for the moſt part procumbent; but this procumbence does not appear to originate in the uſual way, from the weakneſs of the ſtalk, but from its being bent downward at a joint near its baſe; as every ſtem

[1] Thunberg. [2] Retz. [3] Idem. [4] Loureiro. [5] Linn. ſuppl. [6] Retz. [7] Linn. [8] Hort. kew. [9] Smith. [10] Withering. [11] Smith.

is not thus acted on, ſome are frequently found nearly upright: the foliage is of a glaucous hue, and if examined with a magnifier, is found to be covered with numerous rough ſilvery particles; the panicle has a greater degree of rigidity than that of *P. annua*; the ſpikelets are much longer, leſs flat, and more regularly diſtant from each other; and each floret is ciliated at its baſe.

This new graſs is deſcribed and figured in the laſt number of the *Flora Londinenſis* that Mr. Curtis publiſhed.

Dr. Withering remarks, that this has not the bordered fruit-ſtalk of *P. rigida*. He has figured it under the name of *P. rupeſtris*; and deſcribes it as four or five inches high; the culm knee-bent in the upper joint, ſheathed up to the panicle; leaves ſhort, broad, ribbed; panicle an inch and half long, nearly one inch broad; calyx three or four-flowered, with the outer valve three-ribbed; valves of the corolla blunt.

Dr. Smith obſerves, that *Cynoſurus durus*, which is undoubtedly a *Poa*, is very nearly allied to this; ſcarcely differing from it except in its more rigid habit, more ſimple panicle, its flexuoſe flatted ſmooth unſtreaked rachis, and the outer calycine glumes nine-nerved.

He informs us that Dr. Goodenough ſuſpects Mr. Hudſon's full deſcription under his *P. maritima* may belong to this plant.

He obſerves farther, that *P. procumbens*, with *maritima*, *diſtans*, *Feſtuca fluitans*, and *Cynoſurus durus*, form a very natural tribe of *Poa*, with blunt florets, whoſe valves are ribbed, and whoſe ſpikelets are ſcarcely ſo truly ovate as the character of this genus requires. They are joined to the other ſpecies by means of *P. rigida* and *compreſſa*, and, no doubt, form a natural genus with them.

Mr. Curtis firſt diſcovered this graſs in the autumn of 1793, at the foot of St. Vincent's rocks, on the edge of the river. Sir Thomas Frankland found it growing in ſome plenty in the inundated parts of the waſte ground weſt of the wet dock, below Cliſton; and afterwards abundantly on the pier at Scarborough, within the ſpray of the ſea. Mr. Curtis was informed, that it had alſo been found on the Eſſex coaſt. He ſays, that culture produces little alteration in its appearance.

43. Root annual, furniſhed with few fibres. Culms ſeveral, about four inches high, (or from four to eight) almoſt upright, but in maritime ſituations often proſtrate, rigid, round, purpliſh, very ſmooth and ſhining, leafy at the baſe, with two knots or joints. Leaves acute, often involute-ſetaceous, nerved, very ſmooth underneath, rugged above, the length of the ſheath, nearly upright. Sheath ſmooth and very finely grooved. Stipule ſhort, obtuſe, jagged at the end. Panicle rigid, lanceolate, an inch and half to near three inches long, directed one way in a double row, with a flexuoſe winged rachis, and rugged angles. Spikelets linear, pedicelled, ſmooth, from four to eight or ten-flowered. Calycine glumes nearly equal, keeled, acute, appearing roughiſh when viewed with a magnifier. Florets bluntiſh, cylindrical, ſcarcely keeled, altogether nerveleſs, rugged towards the tip; inner glumes ciliate. Filaments the length of the corolla, anthers very minute and ſhort. Nectary, two ſmall glumes, ovate-acute, the length of the germ, viſible only by the help of a microſcope. Germ turbinate; ſtyles branched to the bottom. Seed ovate-acute, convex on one ſide, concave on the other [a].

In *Syſtema Vegetabilium* theſe marks of diſcrimination are given.—Culm rigid, very ſhort. Panicle lanceolate, rigid, decompounded: branches alternate, alternately ſpikeletted; pedicels rigid, ſhorter than the ſpike. Spikelets linear, acute, with eight flowers or thereabouts. Florets ſharpiſh, ſomewhat ſcarioſe at the tip. Calyx keeled.

Dr. Withering remarks, that this may be diſtinguiſhed from all the other ſpecies by the principal or main fruit ſtalk (rachis) being broad on the ſide oppoſite to the direction of the branches, convex, and edged with a paler green border.

Mr. Curtis obſerves, that in dry and barren ſituations, the ſtalks ſometimes are found ſimple, the panicle alſo not branched, and the ſpikelets, inſtead of containing about eight flowers, have no more than three or four. In this ſtate Scheuchzer makes another ſpecies of it. This alteration, from an exceſs or ſcantineſs of nouriſhment, is what moſt plants are ſubject to; and to form ſpecies from ſuch a cauſe, is to multiply plants without end. A complete knowledge of a plant, (particularly of a graſs,) is only to be attained, by obſerving it at the different periods of its growth, in all the various ſituations in which it occurs.

Native of England, Holland, France, Italy and Germany; alſo in Barbary; in dry ſandy or ſtony places, on walls and roofs; flowering from may to auguſt.

44. See the deſcription of this graſs under *Feſtuca ſpinoſa*.

45. Root perennial, creeping, conſiſting of downy fibres, thrown out from the loweſt part of the ſtem, which is decumbent at the baſe, then riſes obliquely, and is upright at top; where it is naked; at bottom it is leafy; the firſt or lower joints are bent, the uppermoſt very long; it is ſtriated, ſmooth and about a foot high, and is very much compreſſed. Leaves flat, acute, of a glaucous green, ſmooth and even. Sheaths the length of the leaves, ancipital, ſtriated, a little ventricoſe. Stipule ſhort, bluntiſh. Panicle glaucous, upright, directed one way, bluntiſh, condenſed, two inches long; with the rachis from roundiſh-flatted; and all the branchlets at firſt cloſe and erect, acutely angular and rough, a little zigzag; as they flower they ſpread conſiderably, but immediately after the diſcharge of the pollen they become again cloſe-preſſed to the main branch, ſo that the upper part of the panicle looks as if it expanded firſt. By this mark the graſs may be known at a diſtance. Spikelets ſubſeſſile, ovate or ovate-lanceolate, much larger than thoſe of *P. pratenſis*. Calycine glumes almoſt equal, ovate, nerved. Florets from three to nine (moſtly three or four, Linneus ſays ſix,) cloſely imbricate, ovate, angular, three-nerved, bluntiſh, purple below the tip, which is ſilvery and ſcarioſe, at the baſe connected by very fine, complicated, ſhorter villoſe hairs [c]. Dr. Withering ſays they are rarely woolly at the baſe.

Native of moſt parts of Europe, in dry paſtures, on the tops of walls that are a little covered with earth, on houſe-tops, and in other very dry places; where it may be found in flower from june to ſeptember, and may be eaſily diſtinguiſhed by its compreſſed ſtem [d].—It is alſo found in North America, where it has uſually three florets in a calyx; the European has commonly more, but the habit and ſtructure is the ſame in both [e].

This Graſs can ſcarcely be put to any agricultural uſe, though all cattle eat it; for it does not thrive in moiſt or manured ground, and there are many better graſſes for dry ſituations [f].

46. 47. Found by Thunberg at the Cape of Good Hope.

48. Culm evidently compreſſed. Panicle ſhort, contracted, ſpike-ſhaped. Inner valve of the corollas linear, curved, ciliate, like *P. ciliaris*; from which it differs in having the cilias many times ſmaller, the culms depreſſed, and the leaves ſhort, ſcarcely an inch in length [g].

According to Linneus, this graſs reſembles *P. compreſſa* very much, but the culm is round; the flowers are panicled, whorled, five-flowered; the anthers red, and the piſtils white.

Native of the Eaſt Indies, where it was obſerved by Koenig.—Retzius remarks, that Phœnix amboinica of Rumphius is very different from this, as appears both from his figure and deſcription.

49. Roots articulate, ſtoloniferous, producing bundles of leafy culms, a ſpan high, and round. Leaves filiform, convoluted, diſtich, ſhort, ſomewhat rigid.

[a] Curtis and Smith.
[b] Smith and Withering. [c] Smith. [d] Linn. [e] Engl. bot. [f] Retzius.

Panicle ovate-oblong, with ſhort ſpreading and very branching peduncles. Spikelets linear-lanceolate. One glume of the calyx longer than the other, which is very near the corolline glume: theſe latter are like thoſe of the preceding: that is, the inner valve is linear and recurved towards the outer valve, and a little ciliate on the back. The colour of the panicle is commonly greeniſh, ſometimes hoary, and not unfrequently blood-red.—The culms, peduncles, pedicels and calyxes are all ſo clammy, as to beſmear the feet and legs of thoſe who walk among this graſs, and cover them with the glumes. It fills the air with an odour of turpentine that is not unpleaſant, eſpecially in the evening. Found in the dry gravelly ſoils of Malabar by Koenig[1].

50. Root creeping a little. Culms ſeveral, upright, a foot and half high, ſlender, ſlightly compreſſed, ſtriated, ſmooth. Leaves almoſt all on the ſtem, narrow, attenuate-briſtle-ſhaped, acute, ſtriated, the upper ones rough on both ſides and at the edge, the lower ones ſmooth underneath. Sheaths ſcarcely the length of the leaves, compreſſed, ſmoothiſh. Stipule very ſhort, crenate. Panicle almoſt upright, diffuſed; branches ſlender, half whorled, angular, rugged, often flexuoſe, more or leſs branched. Spikelets ſharp, ſhining a little, ſmooth. Calycine glumes almoſt equal, a little ſhorter than the ſpikelet, lanceolate, acuminate, three-nerved, rugged on the keel towards the tip. Florets two to four, approximating, lanceolate, acute, ſcarce apparently five-nerved, membranaceous on the edge and at the tip, more or leſs ſilky on the back, ſomewhat hairy at the baſe, but free, and not connected by bundles of villoſe hairs that admit of being drawn out, as in *pratenſis* and *trivialis*: inner valves acute, keeled within, ſubpubeſcent on the margin.

This is the *Poa anguſtifolia nemoralis* of Hudſon.

β. Has a firmer habit, the ſtem and leaves leſs attenuated, the panicle denſer, the florets commonly more numerous. It has the appearance of *P. pratenſis* or *trivialis*; but it is diſtinguiſhed by the florets being unconnected, though hairy at the baſe, more acute, and leſs nerved; and by the ſtipule being very ſhort, ſubcrenate or ciliate: inſomuch that it cannot by any means be aſſociated with them.

This is *P. anguſtifolia* α. of Hudſon; the ſecond variety of *pratenſis* in Withering; and ſeems to be *P. trivialis* of Leers[m].

Native of many parts of Europe, in woods and ſhady places: with us it is more common in the northern parts of the iſland. It flowers in june.

51. This is a very ſmooth graſs, two feet high and more, with a thick culm. The panicle ſcarcely iſſues from the ſheath of the upper leaf. Peduncles long, ſtrict. Calyxes acute, three-flowered, naked, ſhorter than the flowers, alternate, ſeſſile. Obſerved by Koenig in the Eaſt Indies[n].

52. Found by Thunberg at the Cape of Good Hope.

53. Root perennial, fibrous, whitiſh, from which ariſe in cluſters a ſort of bulbs, involved in ſeveral whitiſh or whitiſh brown coats, which are the ſheaths of the leaves, ſtretched out almoſt an inch in length, and produce bundles of leaves, or elſe the culms. Culm a foot high, ſlender, ſmooth, erect, leafy. Leaves ſhort, linear, channelled, bluciſh: ſtem-leaves very ſhort, with long ſtriated ſheaths. Stipule ſhort, bluntiſh. Panicle ovate. Spikelets broad ovate, compreſſed, glaucous, variegated with the colour of dried vine leaves, commonly four-flowered. Calycine glumes ovate, three-nerved, with the keel rugged at the tip, ſilky at the edge, whitiſh. Florets lanceolate, ſilky towards the edge, connected by complicated villoſe hairs at the baſe[o].

Native of Sweden, Germany, Switzerland, France, Spain, Barbary and the Levant. Hudſon found it near Clapham in Surrey, and on his authority it reſts, that it is a native of England. The above deſcription is from the ſpecimen in the Linnean herbarium.

Deſfontaines ſays, that the panicle is looſiſh and purple; that there are ſeveral unequal capillary peduncles from the ſame point; that the ſpikelets are three or four-flowered; that the outer valve of the corolla is mucronate; and that the flowers are often bulbiferous.

54. This graſs is a middle ſpecies between *Poa*, *Cynoſurus* and *Triticum*; on account of the form of the ſpikelets (which are from three to ſix-flowered) it belongs to this genus, although it is different from the other Poas in its habit[p].

Native of Carinthia, Switzerland and Italy, on the tops of the mountains.

55. The whole of this graſs is ſmooth. Culm filiform. Spikelets lanceolate, compreſſed; lower eleven-flowered; loweſt ſometimes three-flowered; upper ones nineteen-flowered. Rachis flat on one ſide, convex on the other. Outer valve of the corolla ovate, keeled, bluntiſh, one-nerved on both ſides. This ſpecies is eaſily diſtinguiſhed from the reſt by its ſimple ſpike a long ſpan in length, with the upper ſpikelets recurved. Native of the Eaſt Indies[q].

56. Culms infracted, ſmooth, covered with the ſheaths of the leaves. Leaves alternate, two inches long, ſtriated, glaucous-green. Sheaths ſtriated, with the mouth bearded, ſhorter than the leaves. Spike an inch and half long, diſtich, almoſt ſimple. Spikelets compreſſed, ſmooth, an inch in length, twenty-five-flowered and more; lower ones with two-flowered pedicels. Valves of the corolla ſcarcely ciliate at the edge[r].

Vahl had it from the Paris garden; and it is ſuppoſed to be a native of Lima.

57. Culms ſeveral, aſcending from the baſe, a hand in height, covered on every ſide with the ſheaths of the leaves. Leaves linear, narrow, even, with thicker ſheaths. Raceme contracted into a ſpike, almoſt the length of the culm, unequal. Outer valve of the calyx ſhort, ovate; inner double the length. Florets diſtant, with the outer valve oblong, acuminate. Anthers yellow, cloven at both ends. Styles feathered, white. It has the habit of a Feſtuca.

Native of Portugal; where it was obſerved by Vandelli[s].

58. Root perennial, fibrous. Culms ſeveral, decumbent at the baſe, about a foot high, (a ſpan, a foot, or a foot and half, *Curtis*: from nine to twelve inches or more, *With.*) round, leafy, ſtriated, ſmooth. Leaves with long ſheaths, ſharpiſh, even, glaucous, flat; the root-leaves a little rolled in. Stipule obtuſe, emarginate. Panicle erect, with the branches in half whorls, angular, rugged, ſomewhat flexuoſe, ſpiked or branched, of various lengths, finally very much bent back. Spikelets linear, ſmooth, from four to ſeven-flowered (five-flowered more or leſs, *Curtis*: five or ſix-flowered, *With.*) variegated with white or purple. Calyx unequal, keeled, ſmall, blunt, membranous at the edge, the outer glume obſoletely three-nerved. Florets remote, almoſt as in *P. aquatica*, ſubcylindrical, very blunt, retuſe, five-nerved, ſcarioſe at the tip; with the inner glumes emarginate[t].

Culms bent at the lower joint. Root-leaves ſhort, ſtiffiſh, ſlender, ſmooth. Stem-leaves ſheathing, rough at the edges near the end. Stipule ſhort, broad. Panicle about three inches long, and two inches wide: branches in diſtant whorls, four or three in a whorl, greatly ſpreading, when ripe more ſo. Calyx ſmooth, one valve twice as large as the other. Corolla ſmooth, ſhining at the edge and the point, not woolly at the baſe, unequal, blunt[u].

Culms oblique, ſlightly elbowed below. Stem-leaves from upright ſpreading, with a ſmooth ſheath. Panicle a hand's breadth or half a foot in length; the lowermoſt branches about five in number. Valves of the calyx ovate, concave. Valves of the corolla nearly equal, but the outer a little larger, concave, bluntiſh; the inner uſually bifid, and, when magnified, appearing to be edged on each ſide with hairs. Germ obovate. Styles ſpreading, branched to the bottom. Nectary, compoſed of two ſmall glumes, ovate and pointed, at the baſe of the germ.

[1] Retzius. [m] Smith. [n] Retzius. [o] Smith. [p] Willdenow. [q] Vahl. [r] Idem. [s] Linn. mant. [t] Smith. [u] Withering.

Though at firſt ſight this graſs bears a near reſemblance to *P. annua*, and no doubt is often miſtaken for it; yet it is conſiderably taller, its leaves narrower in proportion and much more glaucous, its ſpikelets alſo are much narrower as well as longer, and of courſe contain many more florets, which are for the moſt part prettily variegated with pale green and purple; but the chief character which diſtinguiſhes this from *P. annua* and all the other ſpecies, is to be drawn from the branches of the panicle; theſe, as the plant goes out of bloom, are reflected or ſtretched out backwards, ſo as ſometimes to touch the culm: this is effected by little tubercles at the baſe of the branches on their upper ſides only, which increaſing in ſize as the plant advances in its flowering, forces them backwards[s].

Linneus remarks, that the florets are ſo diſtant, that it might eaſily be taken for a ſpecies of *Agroſtis*, if the calyx were not examined.

According to Vahl, *P. divaricata* of Gouan is the ſame ſpecies with this; but the ſpecimens ſent by Jacquin agree exactly with *P. ſulina*, which is certainly very different from *P. divaricata*[t].

Native of the Palatinate, Sileſia, Auſtria and England. Found by Hudſon in Devonſhire, Kent, Yorkſhire and Lancaſhire, on a ſandy ſoil. Mr. Curtis ſays it is common in paſtures and by road ſides, on our ſea coaſts; but that, like *Plantago maritima*, and ſome other plants, it is not confined to maritime ſituations, for he found it, in july 1786, among the graſſy herbage, on the right hand of the horſe-road, leading up the hill to Hampſtead, in tolerable plenty.

Mr. Curtis farther informs us, that ſix years culture made no alteration in the appearance of this graſs, that it flowers from june to ſeptember, and that there does not appear to be ſufficient merit in it to recommend it for agricultural purpoſes.

59. Culms ſeveral, a hand in height, with one or two leaves on them, white or reddiſh. Leaves two or three inches long, with wide ſheaths. Panicle ſubdichotomous, conſiſting of ſix or ſeven branches in pairs, ſpreading out at right angles. Lower branches trichotomous, upper twice trifid. Pedicels more ſwelling at the tip, very ſhort. Calycine glumes hardly to be diſtinguiſhed by the naked eye, unleſs when the florets fall off, and then the pedicels appear forked with the permanent calyxes. Florets acuminate, in threes or fours, a third of a line in length, membranaceous and whitiſh at the tip, little diſtant from each other[u].

It is an annual graſs, native of Montpelier. Desfontaines found this elegant graſs flowering early in the ſpring, in cultivated fields near Maſcar, in Barbary.

He deſcribes the culms as filiform, erect, ſmooth; the leaves awl-ſhaped and ſmooth; the panicle very much branched, the branches capillary, ſolitary in twos or threes, unequal, ſpreading, divaricate, branched at the tip, ſubtrichotomous, branchlets unequal. Pedicels gradually thickening upwards. Spikelets oblong, ſmall, looſiſh, greeniſh white, diſpoſed in looſe bundles. Outer calyx very ſmall; glumes unequal, membranaceous. Inner calyxes of the ſame ſhape. The florets fall off when the ſeed is ripe, leaving the outer calyx on.

60. Root ceſpitoſe, compoſed of ſimple tomentoſe fibres. Culms ſolitary, ſimple, erect, a ſpan high, even, leafy eſpecially at the baſe. Leaves linear, ſmooth, ſomewhat rigid, with long ſheaths and a ſhort ſtipule. Panicle erect, denſe, green and ſilvery, with pubeſcent branched peduncles, and very ſhort erect pedicels. Flowers ovate-lanceolate. Calyx two-flowered, ſeldom three-flowered, never four-flowered, (ſeldom four-flowered, *Leers*) obſoletely pubeſcent, compoſed of two unequal, acute, keeled glumes, nerved on both ſides, ſcarioſe on the edge, green on the back. Outer petals ſimilar to the calyx; inner much more ſlender and narrow, but a little ſhorter.—From the habit, this graſs ſhould be conſidered as an *Aira*, rather than a *Poa*; nor does the number of florets much ſtand in the way, there being for the moſt part only two: the point of the glumes is ſometimes extended into a ſhort awn[x].

Dr. Smith ſuſpects, that Linneus, in his *Syſtema Vegetabilium*, confounded ſome other graſs with this; and hence removed it to this genus; whereas in his *Species Plantarum* it ſtood among the *Airas*. I follow Willdenow, Pollich, Leers, Krocker, Desfontaines, and moſt of our own writers in continuing it here. Krocker approves of Linneus's alteration, on account of the ſpikelets being two or three-flowered, flat, acuminate, imbricate, like the *Poas*.

Native of Germany, Switzerland, France, England, Barbary, in dry paſtures, by way and wood ſides, in barren land, and ſometimes on walls; flowering from june to auguſt.

61. This ſpecies was raiſed from ſeed by Profeſſor Jacquin, and is an annual ſpecies, flowering all ſummer in the open air, but muſt be put into the ſtove in the winter. The ſtems are about a foot and half high; ſcarcely branched, generally proſtrate: the leaves have long ſheaths, and meaſure, excluſive of the ſheath, about ſix inches: the ſheath is hairy and roughiſh: the panicle terminal, contracted, unequally cylindric, and about an inch long, compoſed of lateral ramules thickly placed and preſſed to the general ſpike. The glumes contain from five to eight flowers, and are rather acute; the one ſomewhat ſhorter than the other, which is rather whitiſh and chaffy. The valves of the corolla are ſharp, aculeated on the back, and often purpliſh above. It is an annual graſs; native of Peru[y].

62. Found at the Cape of Good Hope by Thunberg.

63. Culm from two inches to half a foot in height, ſimple, ſlender, erect, ſmooth. Leaves linear, ſhort, even. Panicle or compound ſpike contracted, with ſhort branchlets preſſed cloſe. Florets ovate, of a cinereous ruſt colour, minute, ſhining, villoſe. Calycine glume from two to four-valved, from ſix to eight-flowered: valves equal, ovate, acute, keeled, awnleſs, beardleſs. Upper valve of the corolla ovate, obtuſe, not keeled, ciliate at the edge: lower valve keeled, entire at the edge, the keel appearing ſerrate when magnified, incloſing the upper one at the baſe. Anthers purple. Stigmas villoſe, pale. Seed oblong.

This is a middle ſpecies between *Briza* and *Poa*[z].

Linneus remarks, that the panicle is red, and the cilias of the glumes white[a].

Browne ſays, this little plant ſeldom riſes above ſix or ſeven inches, and is ſuſtained by a very ſlender weakly ſtalk; it is eaſily diſtinguiſhed by its delicate branches, fine leaves and downy head.

Native of Jamaica, (and other iſlands of the Weſt Indies, in dry ſandy grounds). Introduced in 1776, by Monſ. Thouin. It flowers in july and auguſt, and is annual[b].

64. Culms ſeveral, crowded, from ſix inches to a foot in height, filiform, leafy. Leaves from one to two inches long, linear, even, the opening of the ſheaths terminating in long white hairs. Peduncles branched, flexuoſe. Flowers numerous minute. Calyx almoſt equal, acute, keeled; outer valve appearing with a magnifying glaſs very minutely ciliate at the back, five or ſix-flowered. Outer glume of the corolla like the outer calycine valve, but a little larger: inner narrow, recurved, ciliate at the back, but with the cilias ſmaller than in *P. ciliaris*.

The flowers and ſeeds, in a magnifier, appear pellucid. This graſs differs from *P. ciliaris* in the form of the panicle; and the flowers as well as the cilias are ſmaller.

Native of the Eaſt Indies. Koenig ſent it from Tranquebar[c].

65. Culms ſeveral, a ſpan high, aſcending, kneejointed, with about three knots, leafy, ſomewhat angular at top, ſtriated, glaucoſcent. Leaves from erect ſpreading, flat, narrow, acute, rugged above, with all the ſheaths elongated, looſe, a little compreſſed, ſtriated, ſmooth; all the ſtipules lanceolate, acute, thoſe of the ſtem-leaves commonly jagged. Panicle ovate,

[s] Curtis. [t] Willdenow. [u] Gouan. [x] Smith. [y] Jacquin. [z] Swartz. [a] Syſt. veg. [b] Hort. kew. [c] Retzius.

abbreviated,

abbreviated, ſomewhat condenſed; branches in pairs, alternately branched, more or leſs flexuoſe at the baſe, angular above and rugged. Spikelets broad-ovate, compreſſed, glaucous, variegated with whitiſh and purple. Calycine glumes a little unequal, lanceolate-ovate, acute, ſcarcely ſickle-ſhaped, rugged along the keel. Florets lanceolate, ſharpiſh, naked at the edge, rugged along the keel, connected at the baſe by very fine complicated hairs: inner valves ſcarcely ciliate.

This is diſtinct from *P. alpina* in its glaucous colour, more leafy culm, narrower ſharper leaves, rugged above, with longer ſheaths, all the ſtipules of the ſame ſhape, the peduncles flexuoſe, the glumes narrower and connected, and the keel and edge not briſtly and ſilky.

Native of the Highlands of Scotland. Mr. Mackay found it on Ben Nevis. It is a perennial graſs, and flowers in july.

66. Root ſubceſpitoſe, perennial. Herb glaucous. Culm a foot high, erect, round, ſtriated, ſmoothiſh, towards the baſe leafy and having two knots; above ſimple, ſtraight, naked. Leaves lanceolate, bluntiſh, flat, levigated on the back next the baſe, but in other parts rugged. Sheaths the length of the leaves, ſtriated, ſomewhat rugged. Stipules very variable, ſometimes extremely ſhort, incloſed in the ſheath, ſometimes elongated, lanceolate, jagged, eſpecially on the ſtem-leaves. Panicle erect, very much branched, little elongated; branches half-whorled, angular, rugged; branchlets in pairs. Spikelets erect, variegated with blueiſh, whitiſh and purple. Calycine glumes almoſt equal, lanceolate, acute, keeled, obſoletely three-nerved, rugged towards the tip. Florets ſomewhat remote, lanceolate, obtuſe, ſcarioſe at the tip, torn, woolly at the back, ſcarioſe at the edge, ſilky, free at the baſe; inner valves rugged at the edge; rachis flexuoſe, villoſe.

It ſeems to be very different from *P. glauca* of Vahl in the *Flora Danica*; that approaches nearer to *P. nemoralis*[e].

It is probaby *P. glauca* of Withering, though he refers to Vahl. He deſcribes it as ten inches high, the ſtem ſmoothiſh, the leaves rough at the edges, the panicle two inches long, hardly one broad, few-flowered, but little branched, three or four florets in each ſpikelet.

Mr. Fairbairn had it from Scotland. Mr. Mackay found it in the mountains of Bredalbane. It flowers in june and july[b].

67. Height of *P. anguſtifolia*; the leaves much longer, but involuted, ſtriated and aſh-coloured within; panicle of a pleaſant purple colour; corolla lanceolate, ciliate at the baſe; ſpikelets compreſſed. Perennial. Perhaps a variety of *P. anguſtifolia*.

68. Height about a foot. Leaves narrow, often dry at the time of fructification; panicles whitiſh and purple mixed, compoſed of ſpikes which grow in pairs, on waved or flexuoſe peduncles, one ſhorter than the other and nearer to the axis. Spikelets oblong, almoſt cylindrical. Glumes obtuſe, concave. Corollas purple at the baſe. The ſpikelets, in ſhape, reſemble thoſe of *Feſtuca fluitans*. It is perennial.

69. Height two feet. The leaves are not involuted and are wider. The panicles are more branched and open; the ſpikelets oblong, ſmooth but a little rugged. It is perennial, and is found in Dauphiné, with the two preceding, in ſtony places, with Rhododendron and other alpine plants[f].

70. Culms ſtraight, hard, with black knots. Leaves ſtraight, not more than a line wide. Panicle thin, not much diffuſed, violet-colour mixed with green, and of a golden colour on the upper glume. Calycine glumes unequal, mucronate. All parts of this graſs are hard. The ſpikelets are four times ſmaller than thoſe of *alpina*. Native of Switzerland and Piedmont.

71. Culm three feet high, erect. Leaves ſmooth, not more than three lines wide, rough from drawn through the fingers. Panicle a foot long, not much ſcattered, very thin; on looſely branched peduncles, naked for a long ſpace. Calycine valves unequal, mucronate. Florets ſeſſile and petioled. Glumes equal, long, ſlender, marked with lines, and having a white point. Styles large, feathered. All parts are green and ſmooth. The ſpikelets are much larger than in the other Poas, and this graſs has the appearance of an *Avena*, but there are no awns. Found by Monſ. de Sauſſure in Savoy, between Salenche and Chamouny[b].

DESCRIPTIONS, &c.

1. This plant grows naturally in many parts of North America. The root is compoſed of many thick tubers which are faſtened together by fleſhy fibres, which ſpread, and propagate greatly under ground, ſending out many ſmaller fibres which ſtrike downward. In the ſpring ariſe ſeveral foot-ſtalks about ſix inches high, which divide into two ſmaller, each ſuſtaining one leaf, compoſed of five, ſix, or ſeven lobes, the five middle being deeply indented at the top; theſe join together at their baſe, where the foot-ſtalk meets, which is faſtened to the under ſide of the leaf like the handle of a target; the leaves are ſmooth, and of a light green. At the diviſion of the foot-ſtalk comes out the flower, with a large calyx covering it like a ſheath; the flower has nine pretty large white petals, which are roundiſh at the top, and plaited on their borders. The flowers appear in may, and when they fall off, the germ ſwells to a fruit of the ſize and ſhape of the common Hip or fruit of the wild Roſe. This is at firſt green, but when ripe changes to a yellow colour.

[It appears from Evelyn's Kalendar that it was cultivated here in 1664[i].

[a] Smith. [b] Idem. [c] Villars. [d] Haller. [e] Hort. kew.

2. This was ſent to Linnæus from Peter Collinſon, as a ſpecies of *Podophyllum*. He had it from Virginia. Linnæus doubts whether it may not be rather a ſpecies of *Sanguinaria*; ſince it has a ſingle binate leaf, a leafleſs radical ſcape, and an oblong capſule.]

PROPAGATION AND CULTURE.

1. This plant propagates ſo faſt by its creeping roots, that few perſons are at the trouble of ſowing the ſeeds. Every part of the roots will grow, ſo they may be annually parted, either in autumn when their leaves decay, or in the ſpring juſt before the roots begin to ſhoot; they require no other culture but to keep them clean from weeds. It loves a light loamy ſoil and a ſhady ſituation, and is ſo hardy as ſeldom to be injured by the froſt.

DESCRIPTIONS, *&c.*

1. Root perennial, fibrous. Herb ſmooth. Stems upright, riſing to the height of eighteen or twenty inches, ſeldom more, leafy, panicled. Leaves alternate, unequally pinnate, many-paired; leaflets ellipticlanceolate, quite entire. Corolla between bell-ſhaped and wheel-ſhaped, blue. Calyx bell-ſhaped, half-five-cleft[a]: Gærtner ſays, five-toothed. Filaments dilated at the baſe and membranaceous. Capſule clothed with the calyx, ovate-globular, obſoletely three-grooved, thin, ſubpellucid. Seeds fix in each cell, in a double row, faſtened to the inner angle of the cell, variouſly angular, eroded on the ſurface, of a dark ruſt colour. Umbilicus on the middle of the belly[b].]

Mr. Miller remarks, that the lower leaves have eleven or twelve pairs of leaflets, beſides the odd one, that they are broadeſt at the baſe, end in points, and are ſeſſile; that the ſtem-leaves are of the ſame form, but decreaſe upwards in ſize; that the ſtalks are hollow, channelled, and terminated by bunches of flowers which ſit very cloſe, and are of a beautiful blue colour.

Beſides the variety with white flowers, which is very common, and frequently riſes from the ſeeds of the blue; (Linnæus ſays from the ſame root) he mentions another with variegated flowers; and a third with variegated leaves.

The flowers appear at the end of may, and the ſeeds ripen in auguſt.

[Native of Aſia, and of the north of Europe, in Germany, Switzerland, Sweden, Lapland, Denmark. Though very common with us in gardens, it is one of the plants moſt rarely found wild in this country. In the laſt century it was found in Yorkſhire, about Malham Cove, by Dr. Liſter, Mr. Ray and Dr. Richardſon; it has occurred there ſince to Mr. Wood and others; Mr. Gough gathered it in Gordale. In 1764, I found it near Matlock in Derbyſhire; it has ſince been found in the ſame county, near Bakewell by Mr. Whalely, and at the Lover's-leap, Buxton, by Mr. Wood.

Caſpar Bauhin remarks, that this plant has nothing in common with the Valerians except ſomething in the ſhape of the leaves.—It has not indeed the leaſt affinity in appearance, character, ſenſible qualities or medical virtues[c].]

2. The North American Polemonium, has creeping roots, by which it multiplies very faſt. The leaves have ſeldom more than three or four pairs of leaflets, which ſtand at a much greater diſtance from each other than

[a] Smith. [b] Gærtner. [c] Engl. bot.

than thoſe of the common ſort, and are of a darker green. The ſtalks riſe nine or ten inches high, ſending out branches their whole length. The flowers are produced in looſe bunches, on pretty long peduncles; they are ſmaller than thoſe of the common ſort, and of a lighter blue colour. [Linneus remarks that the flowers nod a little, having weaker pedicels; and are not ſtiff and upright, like thoſe of the preceding.

3. Style ſemibifid. The appearance is different from that of the Polemoniums, and the genus is doubtful. This, as well as the preceding, is a native of Virginia[r].

4. Found at the Cape of Good Hope by Thunberg.

5. This alſo is a native of the Cape. It very much reſembles Campanula perſicifolia, but the ſtigma is ſimple, which is the only difference of Polemonium, as two ſtigmas are of Roella[s].]

PROPAGATION AND CULTURE.

1. Sow the ſeeds in the ſpring, upon a bed of light earth: when they come up pretty ſtrong, prick them out into another bed of the ſame earth, four or five inches aſunder, ſhading and watering them until they have taken root; keep them clear from weeds until Michaelmas, and then tranſplant them into the borders of the pleaſure garden.

It is not of long duration; but by taking up the plants in autumn and parting them, they may be continued ſome years: but as ſeedling plants flower ſtronger than offſets, few perſons propagate them by ſlips.

The varieties may be continued by parting the roots at Michaelmas. They ſhould have a freſh light ſoil; if it be too rich, the roots will be apt to rot in winter, and the ſtripes on the leaves to go off.

2. The American ſort may be increaſed by ſeeds or offſets like the other, and is equally hardy, but much leſs beautiful.

Amica nocturna. *Rumph. amb.* 5. 285. *t.* 98. *Flowers alternate.*

DESCRIPTION, *&c.*

The varieties of this are the Tuberoſe with a double flower, the ſtriped-leaved Tuberoſe, and the Tuberoſe with a ſmaller flower; the laſt is mentioned by ſeveral authors as a diſtinct ſpecies, but is certainly a variety. This is frequent in the ſouth of France, whence the roots have been often brought to England early in the ſpring, before thoſe roots have arrived from Italy, which are annually imported; the ſtalks of this are weaker, and do not riſe ſo high, and the flowers are ſmaller than thoſe of the common Tuberoſe, but in other reſpects it is the ſame.

The Tuberoſe grows naturally in India, whence it was firſt brought to Europe, where it now thrives in the warmer parts, as well as in its native ſoil. The Genoeſe are the people who cultivate this plant, to furniſh all the other countries where the roots cannot be propagated without great trouble and care, and thence the roots are annually ſent to England, Holland, and Germany. In moſt parts of Italy, Sicily, and Spain, the roots thrive and propagate without care, where they are once planted.

This plant has been long cultivated in the Engliſh gardens for the exceeding beauty and fragrancy of its flowers; as the roots are too tender to thrive in the full ground in England, there are few perſons who care to take the trouble of nurſing up their offſets, till they become blowing roots, becauſe it will be two or three years before they arrive to a proper ſize for producing flowers; and as they muſt be protected from the froſt in winter, the trouble and expenſe of covers is greater than the roots are worth; for they are generally ſold pretty reaſonable, by thoſe who import them from Italy.

The double flowering is a variety of the firſt, which was obtained from the ſeed by Monſ. Le Cour, of Leyden in Holland, who for many years was ſo tenacious of the roots, even after he had propagated them in ſuch plenty as to have more than he could plant, that he cauſed them to be cut in pieces, to have the vanity of boaſting that he was the only perſon in Europe who poſſeſſed this flower; but of late years the roots have been ſpread into many parts.

[It appears from Evelyn's Kalendar, that the Tuberoſe was cultivated here in 1664*. It is ſaid to have been firſt brought from the Eaſt Indies by Father Theophilus Minuti, who went three times into that country: and to have been firſt cultivated at Boiſgencier (in horto Belgenſeriano) near Toulon. Cluſius firſt ſaw it in december 1594: he had it from Bernard Paludanus, a learned phyſician; and two years after he received farther information of it from Simon de Tovar, who gave it to Paludanus.]

PROPAGATION AND CULTURE.

As there is no other method to propagate the double-flowering Tuberoſe but by the offſets, moſt people are careful to increaſe it; which is done by planting the offſets upon a moderate hot-bed early in march, and covering the bed in cold weather with mats or ſtraw, and in ſummer they muſt have plenty of water in dry weather. In this bed the roots may remain till the leaves decay in autumn, but if there ſhould happen any froſt before that time, the bed ſhould be covered becauſe if the froſt enters ſo low as to reach the roots it will kill them; and if the leaves are injured by the froſt, it will weaken the roots. Where there is due care taken to ſcreen them from froſt, and too much wet, it will be the beſt way to let the roots remain in the bed till the end of november or the beginning of december, provided hard froſts do not ſet in ſooner; for the leſs time the roots are out of the ground, the ſtronger they will be, and the ſooner they will flower; when the roots are taken up, they ſhould be cleaned from the earth, and laid up in dry ſand, where they may be ſecure from froſt and wet; here they ſhould remain until the ſeaſon for planting them again; this ſame method ſhould be practiſed by thoſe who are deſirous to cultivate the ſingle ſort in England, and alſo that with ſtriped leaves muſt be propagated the ſame way.

[r] Linn.

[s] Linn. ſuppl.

* Hort. kew.

I ſhall next give directions for the management of theſe roots, which are annually brought from Italy. And firſt, in the choice of the roots, thoſe which are the largeſt and plumpeſt, if they are perfectly firm and ſound, are the beſt; and the fewer offſets they have, the ſtronger they will flower; but the under parts of the roots ſhould be particularly examined, becauſe it is there that they firſt decay; after the roots are choſen, before they are planted, the offſets ſhould be taken off; for if theſe are left upon the roots, they will draw away part of the nouriſhment from the old root, whereby the flower-ſtems will be greatly weakened.

As theſe roots commonly arrive in England in the month of February or march, thoſe who are deſirous to have theſe early in flower, ſhould make a moderate hot-bed ſoon after the roots arrive, which ſhould have good rich earth laid upon the dung, about ſeven or eight inches deep; this bed ſhould be covered with a frame, and when the bed is in a proper temperature for warmth, the roots ſhould be planted at about ſix inches diſtance from each other every way. The upper part of the root ſhould not be buried more than one inch in the ground; when the roots are planted, there ſhould be but little water given them until they ſhoot above ground; for too much wet will rot them, when they are in an inactive ſtate, but afterward they will require plenty of water, eſpecially when the ſeaſon is warm. When the flower-ſtems begin to appear, the bed ſhould have a large ſhare of air given to it, otherwiſe the ſtalks will draw up weak, and produce but few flowers; for the more air theſe plants enjoy in good weather, the ſtronger they will grow, and produce a greater number of flowers; therefore, toward the beginning of may, the frame may be quite taken off the bed, and hoops faſtened over it, to ſupport a covering of mats, which need not be laid over but in the night, or in very cold weather, ſo that by enjoying the free open air their ſtems will be large; and if they are well watered in dry weather, their flowers will be large, and a great number on each ſtem.

This firſt planting will require more care than thoſe which are deſigned to come after them, for in order to have a ſucceſſion of theſe flowers, the roots ſhould be planted at three different times, viz. the firſt the beginning of March, the ſecond the beginning of april, and the third at the end of that month, or the beginning of may; but theſe beds will require a much leſs quantity of dung than the firſt, eſpecially that bed which is the laſt made; for if there is but warmth enough to put the roots in motion, it is as much as will be required, and this laſt bed will need no covering, for many times thoſe roots which are planted in the full ground at this ſeaſon, will produce ſtrong flowers in autumn; but in order to ſecure their flowering, it is always the beſt way to plant them on a gentle hot-bed. As to the ſecond bed, that ſhould be arched over with hoops, and covered with mats every night, and in bad weather, otherwiſe the late froſts which frequently happen in may will pinch them.

Theſe plants may remain in the beds until the flowers are near expanding, at which time they may be carefully taken up, preſerving the earth to their roots, and planted in pots, and then placed in the ſhade for about a week to recover their removal; after which time the pots may be removed into halls or other apartments, where they will continue in beauty a long time, and their fragrant odour will perfume the air of the rooms where they are placed; and by having a ſucceſſion of them, they may be continued from midſummer to the end of october, or middle of november; but as the ſtems of theſe plants advance, there ſhould be ſome ſticks put down by each root, to which the ſtems ſhould be faſtened, to prevent their being broken by the wind.

It is a common practice with many people, to plant theſe roots in pots, and plunge the pots into a hot bed; but there is much more trouble in raiſing them in this method, than in that before directed; for if the roots are not planted in very ſmall pots, there will be a neceſſity of making the beds much larger, in order to contain a quantity of the roots; and if they are firſt planted in ſmall pots, they ſhould be ſhaken out of theſe into pots of a larger ſize, when they begin to ſhoot out their flower-ſtems, otherwiſe the ſtalks will be weak, and produce but few flowers; therefore I preſer the other method, as there is no danger in removing the roots if it is done with care.

When the roots are ſtrong and properly managed, the ſtems will riſe three or four feet high, and each ſtem will produce ten or twelve flowers or more; and in this the great beauty of theſe flowers conſiſts, for when there are but a few flowers upon the ſtalks they will ſoon fade away, ſo their places muſt be frequently renewed; for the flowers are produced in ſpikes coming out alternately upon the ſtalk, the lower flowers opening firſt; and as theſe decay, thoſe above them open, ſo that in proportion to the number of flowers upon each ſtalk, they continue in beauty a longer or ſhorter time.

The ſort with double flowers will require a little more care, in order to have the flowers fair, but this care is chiefly at the time of blowing, for the flowers of this ſort will not open, if they are expoſed to the open air; therefore when the flowers are fully formed and near opening, the pots ſhould be placed in an airy glaſs-caſe, or a ſhelter of glaſſes ſhould be prepared for them, that the dews and rains may not fall upon them, for that will cauſe the flowers to rot away before they open, and the heat of the ſun drawn through the glaſſes will cauſe their flowers to expand very fair. With this management, I have had this ſort with very double flowers extremely fair, and upward of twenty upon one ſtem, ſo that they have made a beautiful appearance; but where this has not been practiſed, I have rarely ſeen one of them in any beauty.

POLIUM. *See Teucrium.*

POLLIA.

Lin. gen. Schreb. n. 572. *Thunb. nov. gen.* 11. *flor. japon.* 8. *Juſſ.* 45.

Claſſ. 6. 1. Hexandria Monogynia.

Nat. order of *Junci*, Juſſ.

GENERIC CHARACTER.

CAL. none.

COR. ſix-petalled. *Petals*, the three outer ovate, concave, wider at the tip, blunt; the three inner alternate with the outer, bending in, nerved, very ſlender.

STAM. *Filaments* ſix, capillary, curved in at the tip, inſerted into the receptacle. *Anthers* round, twin.

PIST. *Germ* globular, ſuperior. *Style* filiform-ſubulate, incurved. *Stigma* ſimple, blunt.

PER. *Berry* globular, ſurrounded by the permanent reflex corolla.

SEEDS very many (as far as twenty) angular.

ESSENTIAL CHARACTER.

Cor. inferior, ſix-petalled. *Berry* many-ſeeded.

SPECIES.

1. Pollia japonica.

Lin. ſyſt. 332. *Thunb. jap.* 138.[1] *Hornſt. diſſ.* 1. 11, 12, 13.

DESCRIPTION, *&c.*

Stem angular, erect, jointed, little branched, rough with villoſe hairs, two feet high. Branches alternate, ſhort, flowering ſucceſſively, reſembling the ſtem. Leaves on the lower part of the ſtem approximating, on the upper very remote, alternate, embracing, enſiform, nerved longitudinally, entire, ſmooth but feeling rough when ſtroaked backwards, whitiſh underneath, patulous, a foot long, (the upper ones ſhorter) more than an inch wide. Flowers verticillate corymbed. Peduncles verticillate, four to ſix in a whorl, villoſe, green, ſpreading, two or three-flowered, an inch in length. Pedicels ſhort, ſnow-white. Bracte under each peduncle lanceolate, convex, white.

Native of Japan, near Nagaſaki, and of the iſland of Java; flowering in ſeptember'.

Juſſieu doubts whether this plant may not be more nearly allied to the *Aſparagi* than the *Junci*; and whether the fruit be really a berry.

[1] Thunb. jap.

POLLICHIA. (*So named by Dr. Solander, in honour of John Adam Pollich, M. D. author of an History of the Native Plants of the Palatinate of the Rhine.*)

Lin. ſpec. ed. Willd. 23. *Ait. kew.* 1. 5. *Smith ſpicil.* 1. *t.* 1.

Neckeria campeſtris. *Gmel. ſyſt.* 16.

DESCRIPTION, *&c.*

Root fibrous, biennial. Stems ſeveral, inclined, round, inveſted with a thin white down, branched, leafy. Branches moſtly alternate, erect, leafy, many-flowered. Leaves in whorls ſix together, of which the two outermoſt are generally the largeſt, except in the lower part of the ſtem; all ſpreading in various directions, ſeſſile, linear-lanceolate, acute, contracted at the baſe, entire, ſmooth, a little glaucous, ſomewhat ſucculent. Stipules numerous, ſmall, lanceolate, membranous, permanent. Flowers in ſeſſile, oppoſite, axillary cluſters, at almoſt every whorl of the branches, numerous, ſeſſile, ſmall, green. Bractes mixed with the flowers, lanceolate, membranaceous, ciliate. Calyx ſmooth and full of honey. Petals white. Anther tawny. Scales full of ſweet juice.

Native of the Cape of Good Hope, where it was found by Mr. William Paterſon, who tranſmitted the ſeeds to the Counteſs of Strathmore, by which means it was introduced into the Kew garden, and flowered there, for the firſt time in Europe, in the year 1780[*]. It flowers here in ſeptember.

DESCRIPTION, *&c.*

Stem very much branched, diffuſed, divaricating. Leaves oppoſite or in fours, obovate, quite entire, ſomewhat fleſhy, ſmooth. Stipules and bractes acuminate, ſcarious, white. Panicles terminating, dichotomous. Flowers numerous, ſmall. Calyx edged with white. Petals very ſmall, fugacious, white, ſometimes emarginate. Valves of the capſules lanceolate, bent in at the edge[†].

According to Deſfontaines, the whole plant is ſmooth; the ſtems ſometimes erect, ſometimes procumbent at the baſe, round, knobbed, jointed, almoſt

* Smith.

* Willdenow. † Idem.

filiform.

filiform. Leaves on very short petioles, commonly in whorls of four together, unequal. Stipules small; the middle ones membranaceous, white, entire or torn. Flowers panicle-corymbed. Calyx five-parted; the parts keeled, acute. Both he and Hudson remark that the petals are sometimes abortive.

The capsule is small; the valves membranaceous, rolling up inwards after the capsule opens. Seeds many, as far as fifteen, very small, ovate with a beak, shagreened, or before they are fully ripe angular and smoothish, they are of a pale colour[a].

Mr. Woodward observes, that it alters in habit so much by cultivation as hardly to be known at first sight.

This insignificant plant may boast a great variety of names. It is annual, and flowers from may to august, and even in winter.

Native of many parts of Europe, in a dry light soil: as Germany, the South of France, Istria, Italy, Barbary. In the West of England; as in various parts of the coast of Devonshire and Dorsetshire; about Lymston near Exeter, Mr. Hudson; on the neck of the Isle of Portland, close to the shingly beach, Mr. Hudson and Dr. Goodenough. In Portland, at the north end, and about Exmouth in Devon, Mr. Lightfoot. On Chesil bank, A. B. Lambert, Esq;[a]

DESCRIPTIONS, &c.

1. This is a perennial plant, found by Professor Pallas, in a dry salt soil in Siberia.

2. An annual plant, found also in the muddy salts of Siberia, by the Jaik and the lake Altan[y].

3. Root annual. Stem short, branched from the very base. Branches procumbent, simple or subdivided, striated, somewhat hairy, knobbed with a callus at the inside of the base, prostrate. Leaves numerous, keeled, mucronate. Flowers axillary, sessile, solitary. Calycine leaflets constantly two, lanceolate, awned, twice as long as the corolla. Petals five, ovate, acuminate. Stamens three, shorter than the corolla. Germ within a coat, fastened by a thread coming out of the side not from the base. Style bifid, ascending from the opposite side, and perforating the apex of the membrane, as in some of the Chenopodiums. Stigmas globular. A kidney-form dotted seed is inclosed in a thin membranaceous capsule, like that of *Herniaria*, and is let out at the base by a very slight pressure[z].

Gærtner describes the capsule as utricular, roundish, turgidly lenticular, very thin, pale, terminated at top by a double rudiment of the styles. Seed rounded-kidney-form, lenticular, having very minute raised dots scattered over it, rufescent, erect, fastened by a long filiform umbilical cord, ascending from the base of the capsule to the other margin of the seed.

Gærtner commends Adanson for having united this genus with *Camphorosma*, the number of parts in the flowers being so various, as the observations of Pallas have abundantly shown.

Haller describes the flowers as seated between two awned bristles: and Krocker says, there are five calyx-shaped scales, permanent, membranaceous, awned, and no other calyx or corolla visible.

Native of France, Italy, Germany, Switzerland and Austria, in corn fields.

Cultivated in 1758, by Mr. Miller. It flowers in july[a].

4. This is perennial, and was found by Pallas in sandy saltish wet places of Siberia.

5. This is annual, and was discovered by Pallas in salts and marshes near the Caspian sea[b].]

Nat. order of *Lomentaceæ. Pediculares*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved, small: *leaflets* ovate, acute: *two* below the corolla, *one* above that, and *two* in the middle, subovate, flat, very large, coloured, (the wings) permanent.

COR. subpapilionaceous. *Standard* almost cylindrical, tubular, short, with a small reflex mouth, bifid. Wings, *Jacqu.*) *Keel* concave, compressed, ventricose towards the tip. *Appendix of the keel*, in most of the species two, three-parted, pencil-shaped *bodies*, fastened to the keel towards the tip.

STAM. *Filaments* diadelphous (eight connected) inclosed within the keel. *Anthers* eight, simple.

PIST. *Germ* oblong. *Style* simple, erect. *Stigma* terminating, thickish, bifid.

[a] Gærtner. [a] Pulteney's Dorsetshire plants. [y] Willdenow. [z] Leers. [a] Hort. kew. [b] Willdenow.

PER. *Capsule* obcordate, compressed with an acute margin, two-celled, two-valved: *partition* contrary to the valves; opening at each margin.

SEEDS solitary, ovate, (with a glandular umbilicus. G.)

OBS. *The appendix to the keel is different in the several species; and in many the pencil-shaped appendix is wanting; whence they are called beardless.*

In Heisteria *the calyx is five-parted and equal, the corolla not cloven, and the germ four-horned. The fruit of* P. spinosa *is a berry (or a drupe) and the branches are pungent.* Juffieu.

ESSENTIAL CHARACTER.

Cal. five-leaved, with two of the leaves shaped like wings and coloured. *Legume* obcordate, two-celled.

SPECIES.

* *Crested (the flowers having a pencil-shaped appendix).*

[1. Polygala incarnata. *Flesh-coloured Milk-wort.*
Lin. spec. 986. *Reich.* 3. 382. *Pluk. mant. t.* 438. *f.* 5. *Raii suppl.* 639. *n.* 7.
Flowers in spikes, stem herbaceous branched erect, leaves alternate awl-shaped.

2. Polygala alpalatha.

Flowers erected, raceme terminating, ſtem erect branched, leaves lanceolate tomentoſe.

DESCRIPTIONS, *&c.*

1. Root annual. Stem a ſpan or a foot in height, filiform, angular. Branches commonly three, in the upper axils, long, narrow. Leaves flat, very ſharp, remote, ſcarcely eight for the moſt part upon the ſtem. Spikes terminating, ſolitary, oblong, of a very lively fleſh-colour; corollas three times as long as the calycine axils, furniſhed with a multifid dilated fleſh-coloured pencil, erect like the corolla.—Native of Virginia and Canada[s].

Ray informs us that Vernon and Krieg introduced it from Maryland.

2. The ſtems about a foot high. Leaves filiform, acuminate, ſpreading, an inch long; the upper ones ſhorter. Flowers terminating, in a ſort of head, on pedicels the length of the flowers. Under each flower is a lanceolate-ſubulate coloured bracte, the length of the pedicel. Corolla white, with lanceolate wings, and a pencilled keel. It has the appearance of an Aſpalathus.—Native of Braſil. Arduini[t].

[s] Linn. ſpec. [t] Linn. mant.

3. Stems a hand high, filiform, proſtrate, ſometimes, but ſeldom, having a lateral branch. Spike ſtraight, terminating, white, with the flowers on very ſhort pedicels, without bractes. Wings ovate, obtuſe: keel pencilled. Capſules with ſolitary ſeeds. The peduncle of the ſpike lengthens out as the flowers fall off, whence the rachis becomes toothletted.—Native of Braſil [a].

4. Root perennial. Stems erect, ſtriated, even, rod-like. Leaves ſcattered, lanceolate-ſubulate, acute, remote, ſmooth. Spikes terminating, oblong, toothletted below from the falling of the flowers. Keel without a creſt, but inſtead of it a point cut multifariouſly. Corolla minute, white. Awns of the ſeeds turned downwards, briſtle-ſhaped, numerous [b].

Stems herbaceous, ſlender, quite ſimple, or at moſt having a branch or two; covered their whole length with numerous leaves, the loweſt ſometimes above wider and blunt, gradually ſmaller upwards, and the uppermoſt very ſmall. Spikes denſe, an inch long, ſlender. Seeds conical, their blackneſs appearing through the very thin capſules: they are ſurrounded outwardly with long awns, whence with the ſlighteſt compreſſion they fly out of the capſules. The keel equals the wings in length. It has no ſlight affinity with the firſt ſpecies, yet it is abundantly different.—Native of New Granada [c].

5. This agrees ſo much with our common Milk-wort in habit, that it may be eaſily miſtaken for it. The radical leaves are thicker and obovate, wider and very blunt; the ſtem-leaves are more declining. The whole plant, except the root, is always extremely bitter; a leaf ſlightly chewed affects the tongue very ſtrongly, ſoon diffuſes itſelf over the whole jaws, and continues a long time [d].

Scopoli doubts whether it differs from the common ſort. Linneus calls it the daughter of that ſpecies, but having larger leaves, thoſe next the root ten times as big; however very nearly allied to it; diſtinguiſhed chiefly by its bitterneſs.

Krocker remarks, that the ſtems are more declined, not branching, ſhorter, ſomewhat angular, filiform, in tufts. Root-leaves roundiſh, firm, blunt; the upper leaves linear, all quite entire (and in alpine ſituations, as Haller obſerves), all ovate-lanceolate. The flowers, according to Villars, are of a beautiful ſky blue, but vary ſometimes to white.

Probably the ſame qualities which are aſcribed to *P. Senega* may reſide in this, and it might be uſed as a ſuccedaneum for that. Geſner aſſerts, that an infuſion of it purges without any harm. A tincture of four ounces of it in a pint of Canary wine is extremely bitter and of a browniſh colour [e]. It is employed in the pleuriſy, in malignant and milk fevers, and in phthiſis pulmonalis. A dram of the root in powder is given as a doſe: or an ounce of it is boiled in a pint and half of water to a pint, and drank with milk. The ſtimulating and reſolving principles are ſtronger in *P. Senega*, but this ſeems to abound more in a balſamic reſin [f].

It is more efficacious than our common Milk-wort, but that may be owing in great meaſure to its mountainous or ſubalpine ſituation.

Native of France, Switzerland, Sileſia, Auſtria, Carniola, Piedmont.—Introduced in 1775, by Drs. Pitcairn and Fothergill [g].

Allioni conſiders it as being biennial.

6. The perennial woody root throws out many ſpreading procumbent ſtems, clothed with deep green ſmooth leaves, which vary much in ſize and figure. The flowers, commonly blue, are often white, fleſh-coloured or purple, but in all caſes marked with green lines. The permanent calyx turns at length wholly green, and wraps up the young pod, cloſing and drooping to protect it from rain. So the elegant fringed creſt of the corolla protects the ſtamens and piſtil, admitting air, but ſcarcely wet or inſects [h].

Dr. Withering adds, that the ſtems are four-cornered and undivided; the leaves alternate or in pairs, a little rolled back at the edges, the upper lanceolate, the lower ovate; calyx-leaves lanceolate, concave, coloured; wings of the corolla lanceolate, more fully coloured; ſtandard compoſed of two petals, joined by a hairineſs at the edges; keel cylindrical below, but towards the top expanding into two ſets of club-ſhaped glandular appendages. Filaments in two ſets, like two expanded hands with four fingers in each. Anthers yellow or orange. Style thicker upwards. Stigma with two lips, the one a fleſhy knob, the other lanceolate, concave.

Mr. Miller ſays, three or four ſlender, trailing herbaceous ſtalks about ſix inches long, come out from a perennial root; the leaves are about half an inch long, and an eighth part of an inch broad in the middle.

[Capſule ſmall, obcordate, with a groove on each ſide, compreſſed, bordered with a membrane, marked with minute dots in rows. Seeds ruſty brown, covered with whitiſh villoſe hairs, and having a linear hilum or ſcar on one ſide. The umbilicus or navel has a white glandular caruncle unequally triſid, two ſegments larger and equal, the third ſmaller, all linear-acuminate, reflex, united in form of a little crown on the top of the umbilicus. The form and ſituation of this and the embryo, indicate a near affinity between Polygala and the Tithymali or Spurges, as Adanſon ſuggeſted [i].

Linneus found the common Milk-wort to poſſeſs the properties of *P. Senega*, in an inferior degree. Duhamel uſed it in pleuretic caſes, with the deſired ſucceſs; the powdered root may be given in doſes of half a dram [k].

An infuſion of the herb, ſays Dr. J. E. Smith, taken in a morning faſting, about a quarter of a pint daily, promotes expectoration, and is good in a catarrhous cough. I tried it at Montpellier by the advice of Profeſſor Gouan with ſucceſs, and have ſince known it uſeful [l].

Allioni ſays, it has the ſame properties with *P. amara*, but weaker and with leſs of the balſamic principle; that it is not to be deſpiſed as a ſuccedaneum to P. Senega in the Pleuriſy and Peripneumony, and that it promotes expectoration.

Native of moſt parts of Europe, and of Barbary, in dry healthy paſtures and on rocks, flowering in june and july.

Foreign writers celebrate it as a grateful and nutritious food for cattle. According to the Swediſh experiments, kine, ſheep and goats eat it, but ſwine refuſe it.

With us it is found chiefly in dry barren paſtures, heaths or ſheep-walks.

7. This is extremely allied to the P. vulgaris, but the flowers are always of a bright red-purple: the whole plant is alſo larger and more upright. It is found in great plenty in Auſtria according to Profeſſor Jacquin, who conſiders it as diſtinct from the common Polygala; but confeſſes at the ſame time, that he cannot find any other diſtinguiſhing characters than what are mentioned above; ſo that it may perhaps be conſidered as a remarkable variety.

8. Root annual. Stem herbaceous, commonly branched but ſometimes ſimple. Branchlets filiform; ſmooth. Leaves narrow-lanceolate, ſeſſile, very ſharp, ſometimes almoſt awl-ſhaped, cluſtered in ſome, rather remote in others, quite entire. Flowers pedicelled, nodding after floreſcence: wings lanceolate-elliptic, membranaceous, ſharpiſh, pale roſe-coloured or greeniſh, three-nerved, netted [m].

Villars remarks, that it is very ſmall in all its parts, and that it is ſtraighter and harder than *P. amara*. Crantz and Gerard conſider it as a variety of *P. vulgaris*. N. 5, 6, 7, 8. are indeed very nearly allied.

Native of the South of France, Piedmont and Algiers, on dry barren hills. Cultivated by Mr. Miller, in 1759.

9. Root annual. Stem from half a foot to a foot in height, round, ſmooth, divided above the middle. Branches filiform, erect, leafy, ſmooth. Leaves ſub-

[a] Linn. mant. [b] Idem. [c] Jacquin. [d] Idem. [e] Idem. [f] Allioni, Krocker. [g] Hort. kew. [h] Engl. bot. [i] Gartner. [k] Withering. [l] Engl. bot. [m] Jacquin. [n] Desfontaines.

ſeſſile,

ſeſſile, alternate, acute, entire, dotted, ſmooth. Peduncles or racemes terminating, filiform, erect, many-flowered. Flowers minute, purpliſh, nodding, on very ſhort pedicels. Calyx three-leaved, coloured; hinder leaflet larger, ovate, the two anterior oblong, acuminate. Standard conſiſts of two oblong obtuſe erect petals, covering the keel and wings, and converging in front at top: wings leſs than the ſtandard, pale, lanceolate, converging above the keel; which is alſo leſs than the ſtandard, covered, gibbous at the baſe, four-cleft at the tip, deciduous. Filaments ſhorter than the corolla, diſtinct in front, all united below, white and pellucid. Anthers oblong, yellow. Germ ovate, compreſſed a little, convex, twin. Style thick, curved, like a cornucopia. Stigma funnel-form, obliique, bearded at the anterior tip, pellucid. Seed-veſſel, which Swartz calls a filicle, oblong, emarginate at the tip and baſe, compreſſed, convex, two-celled, opening at the ſides, two-ſeeded. Seeds oblong, convex, brown, hairy; appearing echinated in a magnifier[a].

This beautiful little plant is a native of Jamaica, (and Hiſpaniola.) It has much of the ſmell and taſte of the Senega Snake-root; but is not ſo ſtrong or diſagreeable. It is a mild attenuant and ſudorific, and may be adminiſtered in infuſions or decoctions. It grows generally to the height of ſix or ſeven inches, and is ſeldom branched below the middle[b].

10. This has the habit of the preceding. Lower leaves ovate; upper lanceolate. Raceme ſingle, (ſeldom two) looſe, and without bractes at the baſe of the partial pedicels. Native of Siberia[c].

11. There are four varieties of this, particularly diſtinguiſhed in the Amœnitates academicæ. The firſt has the keel longer than the creſt, the ſtem branched, and linear-lanceolate leaves. The ſecond has the leaves linear-ſubulate, and the keel ſhorter than the creſt, with a larger purple flower. The third has ſubulate leaves, the ſtem quite ſimple, and a ſmaller purple flower. The fourth has the leaves linear blunt and rugged, the ſtem branched, the flowers very ſmall, whitiſh or pale purple.—The ſtem is ſhrubby in all, and the bracles are remarkable; whence the trivial name.

Native of the Cape of Good Hope. Introduced in 1787, by Mr. Francis Maſſon[a]. It flowers from may to july; and is a plant of great ſingularity and beauty: the purple of its flowers is brilliant in the extreme[b].

12. Stem ſcarcely ſuffruticoſe, a ſpan high, ſomewhat branched, erect. Leaves ſcattered, acute, erect, ſcarce manifeſtly ciliate. Flowers terminating, copious, in a ſort of umbel. Peduncles filiform, one-flowered, even, almoſt equal. Calycine petals ovate, acute. Allied to the preceding. It is an annual or biennial plant; native of the Cape of Good Hope[c].]

13. Stem ſhrubby, covered with a ſmooth brown bark, riſing four or five feet high, and ſending out ſeveral ſpreading branches towards the top. Leaves about an inch long and a quarter of an inch broad, lucid green, and ſeſſile. The flowers are produced at the ends of the branches; they are large, white on the outſide, but of a bright purple within: wings expanded wide, and ſtandard incurved. It continues flowering moſt part of the ſummer. Each cell of the ſeed-veſſel contains one hard ſmooth ſhining ſeed. It grows naturally at the Cape of Good Hope. [Cultivated in 1707, by the Dutcheſs of Beaufort[a].

14. The whole plant is villoſe; the branches round and rod-like; the leaves ſubpetioled, alternate, mucronate, ſometimes emarginate, an inch long. Racemes axillary and terminating, an inch and half long. Bractes three-leaved, ovate, minute. Calycine leaflets oblong, acute, unequal. Wings roundiſh, three times as large as the calyx, permanent, pubeſcent. Legume oval, emarginate, ſhorter than the wings. It is very nearly allied to the preceding, but differs in the form of the leaves, in its hairineſs, ſmallneſs of the flowers, and ſhape of the wings, which are rounded, not ovate-rhomboidal, acute[a].

15. This is a ſhrub two feet high, branched at top; branches alternate, erect, without ſcars. Leaves ſeſſile, quite entire, ſmooth. Racemes terminating, ſhort. Calycine petals ſubcordate, red, large. Capſule like that of *Thlaſpi*, compreſſed, orbicular, emarginate, bordered. It is allied to *P. myrtifolia*, and has the leaves of *Penæa*.

Native of the Cape of Good Hope, in the mountains, flowering in auguſt[a].

16. This is a ſtout ſhrub, with the branches terminated by a ſtrong ſpine. Flowers axillary, ſeſſile, ſmall, white with a red keel. The fruit is an eſculent berry.—Native of the Cape[a].

β. This variety is placed by Linnæus and Miller under another genus, that of Ulex.] Stem woody and hard, covered with a greeniſh bark when young, but afterwards becoming grayiſh. Branches ſlender and woody. Shoots terminating with ſpines. Native of the Cape.

[17. Found at the Cape of Good Hope, by Thunberg[a].

18. Stem white at bottom, as in *Betula* or the Birch-tree. Native of Japan and Java[a].

19. Stem green, even, branched, high. Leaves ſeſſile, acute, ſmall. Peduncles axillary, briſtle-ſhaped. Flowers ſmall. Capſules oblong, two-horned at the tip. Native of the Cape of Good Hope[a].

20. Native of South America. A ſhrub[a].

21. This is a ſmall tree, with looſe rod-like branches, ſubdivided, even, round. Leaves alternate, elliptic, acuminate, blunt at the tip, entire, ſmooth on both ſides, on ſhortiſh petioles. Flowers axillary, crowded. Peduncles axillary, longer than the petioles, ſcaly, many-flowered. Corollas ſmall, greeniſh white. Calyx three-leaved: leaflets ovate, green, permanent; one ſuperior. Standard of the corolla of two lower, reflex, whitiſh petals: wings large, ovate, on the outſide of the ſtandard and keel, ſimilar to the calyx-leaves, permanent: keel larger than the ſtandard, concave, green. Filaments open in front, free at the top, very minute. Anthers minute. Germ roundiſh, compreſſed. Style the length of the ſtamens. Stigma obtuſe. Seed-veſſel or ſilicle pedicelled, roundiſh, compreſſed, emarginate. Seeds reniform-oblong.—Native of Jamaica, in woods, but not common[a].

Browne calls it Baſtard *Lignum Vitæ* of the red hills, where this ſhrub grows very plentifully, generally riſing to the height of ſeven or eight feet, or more. It is called there Baſtard *Lignum Vitæ*, becauſe it taſtes not unlike the gum of that wood, and is ſometimes uſed for the ſame purpoſes.

Swartz does not ſee why Linnæus named it *diverſifolia*, the leaves being all alike; the reaſon however, whether well-founded or not, is apparent from the ſpecific character.

22. Stems rod-like, a foot high, filiform, green, toothed with the baſes of the deciduous leaves. Theſe are the ſmalleſt of any, alternate, remote, ſeſſile, awl-ſhaped or elliptic. Racemes terminating, ſhort. Flowers rather large.

Native of Spain and Portugal. *Aſtroemer*[a].

23. Stem ſtriated a little. Leaves alternate, diſtinct, veinleſs, naked, an inch long, articulated as it were into the petiole. Racemes terminating, two or three, often longer than the leaves. Standard of the corolla blue. Capſules ovate, wrinkled, pendulous, hard.

Native of New Granada, found there by Mutis[a].

24. Stem erect, round, ſoftly hairy. Leaves on very ſhort petioles, an inch long, ſmooth above, ſomewhat hairy underneath. Racemes both oppoſite to the leaves and terminating, three or four inches long, villoſe. Peduncles toothletted from the fall of the flowers. Bractes minute, deciduous. Flowers nodding, a little larger than thoſe of the common ſort. Calyx-leaves ovate, concave. Wings green. Keel violet. Capſules oblong, ſmooth. Seeds villoſe

backwards,

backwards, oblong, cylindric. It is different from *P. violacea* of Aublet, which has crested flowers, and a herbaceous ſtem. Found by von Rohr in Cayenne[m].

25. Stems a foot high, decumbent, woody, not ſmooth. Leaves quite entire, the ſize of the outer joint of the thumb, ſubpetioled, naked, blunt with a point. Branches lateral, very thinly diſpoſed. Spikes lateral, often longer than the leaves, green.

Native of the Eaſt Indies[n]. How comes this to be the ſame with the larger Polygala of Browne, which he found in the woods of St. Elizabeth's, Jamaica, and is frequently above twenty feet in height?]

26. This riſes with a ſlender, branching, woody ſtalk, about a foot high, when it grows upon good ground, but on a rocky ſoil it is ſeldom more than half that height. The branches are cloſely garniſhed with ſtiff, ſmooth leaves, of a lucid green. From between the leaves, towards the top of the branches, the flowers come out upon very ſhort peduncles; they are white on the outſide, but within are of a purpliſh colour mixed with yellow, and have a grateful odour. The ſeed-veſſels are ſhaped like thoſe of P. myrtifolia.

[It is an elegant little evergreen ſhrub of low growth, with leaves like thoſe of Box, producing flowers from may to october, but moſt plentifully in may and june. Each flower ſtands on a peduncle proceeding from a kind of triphyllous cup, formed of floral leaves; the true calyx is compoſed of three leaves, which are nearly white; the two outermoſt petals, ſimilar to the wings of a papilionaceous flower, are alſo white, or nearly ſo; the third petal, which forms a kind of tube, and contains the ſtamens and piſtil, is white at the baſe, but yellow towards the extremity, where it changes by degrees to a bright bay colour.—Cluſius gives an accurate deſcription and good figure of this plant, which was before unnoticed by any author[o].

Villars remarks, that the keel or lower petal has two little ears at its extremity; and that the plant bears little reſemblance to the preceding European ſpecies. Tournefort, Haller and others have conſidered it as of a different genus.

It differs, according to Scopoli, from the others, by its three-leaved perianth; the upper leaf convex, covering the germ and an elliptic cavity, left by the upper gape of the tube of the corolla and the curved baſes of the wings. Corolla one-petalled, with the tube gaping at the baſe on the upper ſide, where the germ is; the border trifid, the two upper ſegments like wings, the lower ovate, longer, contracted behind, having two little ears at top. Filaments four on each ſide, ſlightly united at the baſe. Style flaccid. Stigma cylindric, bifid; the upper ſegment tubular, larger, the lower acuminate. Capſule margined, rugged, naked.

Cluſius and Jacquin mention a variety of this plant, with the calyx and wings of a beautiful purple. Scopoli has noticed four varieties: 1. With white wings, and a yellow keel. 2. With white wings, and the keel red at the tip. 3. With red wings and the tip of the keel yellow. 4. With red wings and keel, but the tip of the latter variegated with red and yellow.

Native of Auſtria, Switzerland, Alſace, Germany, Dauphiné, and Italy, in mountains.—Cultivated in 1658, in the botanic garden at Oxford[p].

27. Stem ſhrubby, procumbent, branched: the branches covered with leaves and flowers. Leaves very much crowded, at each point three or five, ſeſſile, not rigid, hairy underneath and at the edge. Flowers among the leaves, ſhorter than the leaf. Calyx glumoſe, ſmooth, like that of *P. Heiſteria*. Native of the Cape of Good Hope[q].

28. This is a ſhrub extremely reſembling the preceding ſpecies, but with the leaves of *P. Heiſteria*, cylindric, very much crowded, mucronate, even, not ovate-lanceolate or ciliate or flat. The flowers are like thoſe of *Alopecuroides*, and not of *Heiſteria*. Native of the Cape.

29. Stem fruteſcent, rod-like. Buds alternate, from each briſtle. Leaves numerous, ſeſſile, ſpreading or reflex, ſtiffiſh like thoſe of Androſace. Flower from little leafy roſes, often ſolitary, purpliſh, like that of *P. Heiſteria*.

Native of the Cape[r].

30. This is a polymorphous plant, when young very different from what it is when it becomes old: α, with ovate leaves, ciliate on the edge and keel—β, with linear rugged leaves—γ, with awl-ſhaped hairy leaves.—Fruit four-horned[s].

In the courſe of a few years it becomes a ſhrub of conſiderable ſize, equalling a ſmall furze bu h, to which it bears a diſtant reſemblance; and perhaps *furze-leaved* would have been a more expreſſive name than heath-leaved.

The purple of the flowers is brilliant in the extreme, and they are plentifully produced almoſt the year through.

After receiving various names, this plant has been finally placed in the genus *Polygala*; it retains the trivial name of *Heiſteria*, which had been beſtowed on it, in honour of Profeſſor Heiſter, the celebrated German Surgeon.

In Holland it appears to have been long ſince known, but was a ſtranger here[t], till introduced from the Cape of Good Hope by Francis Maſſon, in 1787[u].

31. Stem filiform. Leaves ſeſſile, ternate, linear-ſubulate, flatiſh, mucronate, the middle one longer than the two others. Calyx glumoſe as in *P. Heiſteria*. Fruit in this genus different in the ſeveral ſpecies; but in this ſpecies very much reſembling that of *P. Heiſteria*, of which this plant was originally the daughter. Native of the Cape of Good Hope[x].

32. Root perennial, woody, branched, contorted, about the thickneſs of a finger, and covered with aſh-coloured bark. It ſends up ſeveral ſtems, which are ſimple, erect, ſlender, round, ſmooth, of a dark red-diſh colour, and about a foot in height. Leaves alternate, acute, pale green, on ſhort footſtalks[y].] The flowers are produced in looſe terminating ſpikes; they are ſmall, white, and ſhaped like thoſe of the common ſort, but their keel has no beard or creſt. It flowers here in july, but does not produce ripe ſeeds. It grows naturally in moſt parts of North America, [and was cultivated by Mr. Miller, in 1759[z].

The root of this plant, under the name of Rattle-ſnake root was firſt introduced to the attention of phyſicians near ſeventy years ago, by Dr. John Tennent, whoſe intercourſe with the Indians led him to diſcover that they poſſeſſed a ſpecific remedy for the bite of the Rattle-ſnake, which for a reward was revealed to him, and found to be the root of this plant. He was afterwards fully convinced of the efficacy of this medicine from his own experience: and obſerving that pleuretic or peripneumonic ſymptoms were generally produced by the action of this poiſon, he inferred that this root might be an uſeful remedy in ſuch diſorders. It was accordingly tried in pleuriſies, not only by Tennent himſelf, but by ſeveral French academicians and others; who all unite in teſtimony of its good effects. However, in many of theſe caſes, recourſe was had to the lancet. The repute which this root obtained in peripneumonic affections, induced ſome to employ it in other inflammatory diſorders, particularly in rheumatiſm. It has been preſcribed with much ſucceſs in dropſies; and this we can the more eaſily credit, from its effects in increaſing the different ſecretions; for it produces a plentiful ſpitting, increaſes perſpiration and urine, and frequently purges or vomits. It is likewiſe reported to be a medicine of great power, in rendering the fizineſs of the blood more fluid: De Haen however brings a ſtrong fact to contradict this report. The uſual doſe is from one ſcruple to two of the powder; or two or three ſpoonfuls of a decoction, prepared by boiling an ounce of the root in a pint and half of water, till it is reduced to a pint. A little Madeira wine is moſt effectual for removing

[m] Vahl. [n] Linn. ſpec. [o] Curtis. [p] Hort. kew. [q] Linn. mant. [r] Linn. ſuppl. [s] Berg. in Linn. ſpec. [t] Curtis. [u] Hort. kew. [x] Linn. mant. [y] Woodville. [z] Hort. kew.

the pungent taſte, and making the medicine ſit eaſy on the ſtomach[a].

Ray informs us, that Krieg gathered it in Maryland, but its virtues were not then known.

33. Leaves not unlike thoſe of the common ſort, frequent on the ſtem. Spike terminating, large for the ſize of the plant, compoſed of yellow flowers cloſely ſet on it. Vernon brought it from Maryland[b]. Petiver gives it the epithet of *virginiana*, and Plukenet of *floridana*, it is therefore probably a native of moſt parts of North America. Linnæus marks it as annual.

34. Root annual. Stem a ſpan or a foot high, angular, without any branches. Leaves alternate, linear or linear-lanceolate, even, quite entire. Head of flowers terminating, ſubglobular, greeniſh with a mixture of duſky red in the wings of the flower. Native of Virginia[c].

35. Stem the length of the finger, without branches. Leaves quite entire, long, acute. Flowers axillary, on ſolitary branched peduncles, commonly three-flowered, ſhorter than the leaf. Corolla white. Annual. Native of Ceylon.

36. This has the appearance of our common Milkwort. Stems ſeveral, filiform, undivided, quite ſimple, a finger's length. Leaves obovate, ſomewhat oblong, ſmooth, ſcarcely petioled. Raceme axillary, capillary, containing a few white flowers, ſhorter than the leaves, branchletted, not racemed or ſpiked. Native of Ceylon. Perennial.

37. Root annual. Stem a finger's length, tender, angular, branched. Leaves ovate-lanceolate, ſeſſile, ſmooth, quite entire. Spikes longiſh, pedunculed. Flowers ſeſſile, directed one way. The calyx has five acute ſmall leaflets, and hence recedes from the other ſpecies. Seeds globular.

Native of Ceylon, being found in Herman's herbarium[d], now in the poſſeſſion of Sir Joſeph Banks.

It varies with heart-ſhaped leaves, and ſtems half a foot high and branched[e].

38. Root annual. Stem from a ſpan to a foot in height, firm, angular, with the branches higher than the ſtem. Leaves alternate, narrow-lanceolate. Spikes terminating, looſe, blood-red, ovate. The lower flowers, when mature, drop off, whilſt new ones are coming on, whence the peduncle is jagged or ſquarroſe. Native of Virginia[f].

39. Root annual. Leaves commonly five at a joint, ſometimes alternate. Spikes white, very narrow, with the flowers remote. Stem ſlender[g].

This little plant is exceedingly branched, and at each joint puts forth four or five narrow oblong leaflets. On the tops of the ſtems and branches it produces ſlender oblong ſpikes compoſed of whitiſh flowers.

Native of Maryland. Probably it does not differ from P. quadrifolia minor *Virginiana*, ſpica parva rubente. *Bauh. cat. virg.*[h] If ſo, it is a native of that province alſo.

40. The head of flowers is of a green ruſeſcent colour[i]. Native of Virginia.

41. This is a procumbent branched ſhrub. The older branches are tubercled and jointed; the younger ones are ſmooth. Leaves perennial, very ſmooth, alternate, ſubſeſſile. Flowers raceme-headed, terminating; each pedicelled, the ſame ſize with the common ſort. Calyx five-parted; the three outer parts ſmall, concave, oblong; the two inner much larger, elliptic, coloured, whitiſh at the edge, greeniſh in the middle, ſubpedicelled, reſembling wings. Corolla two-lipped: upper lip cloven, longer than the lower, appendicled, with narrow ſegments ſomewhat bowed; lower lip keeled, two-lobed at top and fringed. Stamens in two bundles. Capſule flat, obcordate, two-celled, two-ſeeded.

Native of mount Atlas, in fiſſures of rocks; flowering early in ſpring.

42. Stems frequently very much branched: branchlets filiform, pubeſcent. Leaves alternate, ſcattered, ſmooth, perennial; lower elliptic, blunt; branch-leaves narrow-lanceolate, ſubſeſſile. Flowers like thoſe of the preceding; from which it differs in having lanceolate leaves, more ſlender and acute, and pubeſcent branchlets. Native of the ſame places.

43. Stems ſeveral from the ſame common tuft, ſmooth, ſlender, erect. Leaves alternate, ſmooth; thoſe next the root elliptic, blunt; the upper ones lanceolate, acute. Flowers pedicelled, nodding after flowering time. Wings elliptic, blunt, bright roſe-coloured, netted, a little larger than thoſe of the common ſort. Calyx five-parted: the three outer ſegments ſmall and ſubulate; the two inner roſe-coloured, ovate, blunt, reſembling petals. Corolla tubular: upper lip two-lobed; lower fringed at the top, bright roſe-coloured, often exceeding the wings. Capſule flat, obcordate, with a membranaceous rim, two-celled, two-valved. Seeds brown, oblong, pubeſcent, warted at top. It is allied to the common ſort, but is larger in all its parts: and the ſtem is fruteſcent at the baſe. Native of mount Atlas near Tlemſen[k].]

44. Root perennial. Stems two or three, about eight inches high, dividing into ſeveral erect branches. Leaves ſmall, of a dark green colour. Flowers ſmall, of a purpliſh blue colour. Native of Maryland.

45. Root perennial, taper, running deep in the ground. Stems ſeveral, ſlender, ſix or ſeven inches high. Leaves an inch long, and half an inch broad in the middle, drawing to a point at both ends. The flowers are produced in looſe ſpikes; they are larger than thoſe of the common ſort, and of a blueiſh purple colour. It was diſcovered by Dr. Houſtoun at Vera Cruz in New Spain.

PROPAGATION AND CULTURE.

5, 6, 7, 8. Sow the ſeeds ſoon after they are ripe. They are rarely admitted in gardens, nor do they thrive well there.

13. This plant is propagated by ſeeds, which ſhould be ſown in ſmall pots, filled with light loamy earth; ſoon after they are ripe, theſe pots may be placed where they may have the morning ſun only till October, when they ſhould be placed under a hot-bed frame, and plunged into old tanners bark, which has loſt its heat, where they may be defended from froſt during the winter, and in the ſpring the pots ſhould be plunged into a moderate hot-bed, which will bring up the plants. When theſe appear, they ſhould not be too tenderly treated, but muſt have a large ſhare of free air admitted to them; when they are fit to tranſplant, they ſhould be carefully ſhaken out of the pots, and ſeparated, planting each into a ſmall pot filled with ſoft loamy earth, and plunged into a very moderate hot-bed to forward their taking new root, obſerving to ſhade them from the ſun, and gently refreſh them with water as they may require it, but they muſt not have too much wet. When they are rooted, they muſt be gradually inured to the open air, and in June they may be placed abroad in a ſheltered ſituation, where they may remain till the middle or latter end of October, according as the ſeaſon proves favourable; then they muſt be removed into the green-houſe; and treated in the ſame way as Orange-trees, being careful not to give them too much wet during the winter ſeaſon. In the ſummer they muſt be placed abroad with other green-houſe plants, where, by their long continuance in flower, they will make a fine appearance.

[This, and the other Cape ſorts (11, 12, 15, 16, 17, 19, 27, 28, 29, 30, 31) may be increaſed by cuttings, ſome more readily than others.]

26. This plant is very difficult to cultivate in gardens, for it commonly grows out of the fiſſures of rocks, ſo cannot be eaſily tranſplanted, and the ſeeds are with difficulty obtained from abroad; nor do theſe vegetate till they have been a whole year in the ground, unleſs they are ſown ſoon after they are ripe, when the plants will come up the ſpring following; when the plants firſt come up, they make very little progreſs here, and are as difficult to tranſplant as almoſt

[a] Woodville. [b] Ray. [c] Linn. ſpec.
[d] Linn. zeyl. [e] Linn. ſpec. [f] Id. ib.
[g] Id. ib. [h] Ray. [i] Linn. ſyſt.
[k] Desfontaines.

any plant at preſent known, which occaſions its preſent ſcarcity in England.

The beſt method of cultivating this is by ſeeds, which ſhould be procured as freſh as poſſible from the places of its natural growth, and ſown in pots as ſoon as it arrives; the pots may be plunged into the ground, where they may have only the morning ſun. If the ſeeds are ſown before Chriſtmas, there will be a chance of the plants coming up the following ſpring; but thoſe which are not ſown till towards ſpring, will remain in the ground a year; therefore the pots ſhould be plunged into the ground, where they may have but little ſun the following ſummer, and in autumn they may be removed, and plunged into an old tan-bed under a hot-bed frame, where they may be protected from ſevere froſt; for although this plant is a native of the Alps and other cold mountains, yet as the ſeeds will not be covered with ſnow here, as they are in their native ſoil and ſituation, they are frequently ſpoiled by the inconſtancy of the weather in England. When the plants come up, they ſhould be placed in ſhade during ſummer; and in autumn they may be turned out of the pots, and planted in a border where they may have only the morning ſun, for this plant will not thrive long in pots. If the winter proves very ſevere, it will be proper to cover the ſurface of the ground about their roots with mulch to keep out the froſt. If the plants take root in the border, they ſhould remain there undiſturbed, and be only kept clean from weeds, for the ground about their roots ſhould not be dug or dunged.

[Boxleaved Milkwort is not now regarded as a plant difficult of cultivation.' It has creeping roots, and ſuch plants are generally increaſed without difficulty, and ſo is this. Planted in bog earth on a ſhady border, it thrives extremely well, and ſpawns much, ſo that there is no neceſſity of having recourſe to its ſeeds'].

3t. The ſeeds of the Snake-root Milk-wort rarely ſucceed; the beſt way therefore to propagate it, is to procure the roots from America, and to plant them in a bed of light earth, in a ſheltered ſituation. In ſummer keep them clean from weeds, and cover the ſurface of the ground about their roots with old tanners' bark, or any other kind of mulch, in winter, to keep out the froſt.—Theſe directions apply to the forty-fourth ſpecies.

45. This is too tender to live in the open air in England, and not thriving in a pot, is difficult to preſerve here. It is propagated by ſeeds procured from abroad. The ſeeds ſent by Houſtoun remained a year in the ground before the plants appeared, and the plants lived only one year.

35. Polygonum ciliatum.
Lour. cochinch. 243.
Flowers octandrous trigynous, ſtipules ſtriated blunt ciliate, ſpikes very ſhort.

36. Polygonum odoratum.
Lour. cochinch. 243.
Flowers octandrous trigynous, ſpikes long terminating, root creeping.

DESCRIPTIONS, *&c.*

The flowers in *Biſtorta* are in terminating ſpikes, nine-ſtamened, three-ſtyled, with a triangular ſeed and a twice-turned root. In *Perſicaria* they are ſpiked and panicled, axillary and terminating, with five, ſix, ſeven or eight ſtamens and two ſtyles or ſometimes three ſtyles, with an ovate ſeed. In *Polygonum Tournef.* they are axillary, eight-ſtamened, three-ſtyled, with a round ſeed. In *Fagopyrum* corymb-panicled, eight-ſtamened, three-ſtyled, with a triangular ſeed[a]. The outer cruſt of the ſeed is thick and hard enough in ſeveral ſpecies of *Polygonum* to be accounted a nucamentaceous pericarp.

1. Calyx five-leaved; leaflets when ripe equal or unequal, coloured or uncoloured, but conſtantly looſe from the ſeed. Corolla none. Stamens eight. Germ ſuperior. Styles three. Pericarp none, except the outer cruſt of the ſeed. Seed ovate-acuminate, three-ſided, ſhining, of a very dark cheſtnut colour, faſtened to the bottom of the calyx: outer cover cruſtaceous-coriaceous; inner membranaceous: albumen farinaceous, very white: embryo on one ſide: cotyledons ſhort, curved, incumbent[b].

Native of Siberia. Introduced in 1770, by Monſ. Richard. It flowers in july[c].

2. See the deſcription, &c. under *Atraphaxis undulata.*

3. Root perennial and not eaſily extirpated, ſomewhat woody, more or leſs bent or crooked, whence its names *Biſtort Snakeweed* and *Adder's-wort*, outwardly of a cheſtnut, inwardly of a fleſh-colour, furniſhed with numerous fibres and creepers. Stem from one to two feet high, quite ſimple, ſtraight, upright, round, ſmooth, ſwelling at the joints. Leaves waved, veiny, entire, ſmooth, of a fine green, and glaucous beneath, their baſe running down ſo as to render the footſtalk winged. The bottom leaves are rather cordate-lanceolate. The ſtalks of the ſtem-leaves are dilated and ſheathing, or ariſe from long ſheaths incloſing the ſtem; theſe ſheaths are membranous and withered at top, and the mouth is oblique. Spike ſolitary, terminating, cylindrical, blunt, nearly upright, compoſed of many beautiful pink-coloured flowers, having the proper number of ſtamens and ſtyles that belongs to the genus, and ſtanding on a ſlender red pedicel, with a pair of membranous bractes at the baſe[d]: the lower of theſe is three-cuſped, the middle point running out into a kind of awn: pedicels longer than the calyx[e]. Each pair of bractes (or common calyx of two valves) contains two flowers, one on a pedicel, the other ſeſſile ſurrounded with a kind of proper cup, thin, membranous, nearly cylindrical, with an even very entire mouth. One of the bractes (or valves) is large, truncate, the other ſmaller and terminated by a ſkinny projection[f]. The nectary is ſeveral ſmall red glands in the bottom of the calyx. Filaments longer than the calyx[g]. Anthers double, the two parts being only united by the filaments[h]; they are of a purpliſh colour. Germ deep red: ſtyles the ſame length with the ſtamens: ſtigmas ſmall and round. Seed three-ſided, pointed, dark brown, and ſhining as if varniſhed[i].

Native of many parts of Europe, Siberia, and Japan. In Britain it is moſt common in the northern parts, particularly in moiſt meadows, where it is often a noxious weed, frequently forming large patches, and not eaſily extirpated; it flowers in may and june. Near London it occurs at Batterſea, and in a meadow by Biſhop's-wood near Hamſtead; in meadows about Uxbridge; near Rickmanſworth in Hertfordſhire; Hyde Mill, Luton, and Thurleigh in Bedfordſhire; banks of the Iſis beyond Iſley, and near Goſford-bridge in Oxfordſhire; Ham-green near Mathon and Martley in Worceſterſhire; near the infirmary, Staffordſ; cloſes near Howes houſe, Whitwell and Shelford, Cambridgeſhire; Brome and Heigham in Norfolk; Tamworth and Fazeley in Warwickſhire; near Derby; Coſgrave in Northamptonſhire: Lenton in Nottinghamſhire; about Sheffield, Hallifax, Bradford and Settle in Yorkſhire, very common; Kendal in Weſtmoreland; near Newcaſtle upon Tyne. In Scotland, about Inverary.

The root of Biſtort, being one of the ſtrongeſt vegetable aſtringents, might well be applied to the purpoſe of tanning leather, if it could be procured in ſufficient quantity. The young ſhoots are eaten in herb

[a] Juſſieu. [b] Gærtner. [c] Hort. kew. [d] Smith. [e] Curtis. [f] Withering. [g] Curtis. [h] Wich. [i] Curt.

pudding

pudding in the north of England, where the plant is known by the name of *Easter Giant*: and about Manchester they are substituted for greens, under the name of Patience Dock [x].

The root was formerly considered to be alexipharmic and sudorific; but its uses seem only to be derived from its styptic powers. Dr. Cullen frequently employed it in intermittent fevers; and gave it both alone and with Gentian, to the quantity of three drams a day. The dose of the root in substance is from a scruple to a dram [y].

4. This has the same habit with the preceding, but is much less. Stem a hand or hardly a span in height, (according to Villars only two or three inches). Leaves linear-lanceolate, veined, sometimes hirsute underneath; the root-leaves often elliptic-roundish [z]: stem-leaves linear, arising from a sheath, which incloses the stem, and is terminated by a blunt membrane [a]. Spike linear, blunt. Flowers rose-coloured, (whitish, *With.* often white, seldom purple, *Krock.*) with eight stamens and three styles [b], the lower ones frequently changing, as Clusius, Boccone, Linneus, &c. observe, into vegetating bulbs, whence the trivial name of the plant: these bulbs are darkish purple, ovate, mealy and white within [c]. Germ acutely three-sided. The seeds are seldom perfected [d].

According to Scopoli, the leaves are lanceolate; the spike slender, two inches long, with the axis three-cornered; peduncles solitary, shorter than the calyx, which is white; bractæ ovate, acuminate, permanent; stamens eight, with the filaments alternately shorter; anthers two-horned, of a dusky rufous colour; styles two terminated by a pellucid ferruginous globule.

The roots of this species have the same qualities with the preceding; they are eaten by the northern nations, and in some parts of Siberia and Tartary [e].

Plants cultivated during four years in a garden constantly produced perfect seeds in july, and flowered as constantly a second time in september. These latter germs vegetated on the stem [f].

Native of many parts of Europe, in mountainous pastures. In England, in several parts of Westmoreland, as at Crosby Ravensworth, found by Mr. Lawson, in fields between Shap and Hardingdal, by Mr. Gough; shewn to Mr. Ray by Thomas Willisel, near Wherf, near the foot-way leading thence to Settle; on the edge of Lemer water at Carr End, Wensley Dale by Mr. Curtis. In Scotland not unfrequent in dry stony pastures by the sides of mountains, as about the pass of Killicranky, near Blair, about Lock Rannoch in Perthshire, Loch Urn in Invernes-shire, &c. and on Benhuardal, in Strath, in the isle of Skye [g]. Dr. Smith found it near the top of Ben Lomond.

Welsh Bistort is a small variety, about four inches high, with the root-leaves roundish and minutely serrate. It was found by Lhwyd, on a very high rock near Lhan-berys [h].

5. Stems hard, round, green, with great joints on them. Leaves large, broad, dark bluish green, with long points on them, often spotted, but often also without marks, many six inches long or more, and three inches and a half broad, with sundry compassing veins from the midrib, and others smaller transverse. At the tops of the stalks, and from the joints of the leaves, spring spikes of white flowers, succeeded by flat, black, shining seeds. Root perennial, consisting of a great bush of long black fibres [i].

Calyx one-leafed, four-cleft. Stamens five. Germ superior. Styles two, filiform. Seed ovate, lenticular-compressed, very smooth and shining, of a pale chestnut colour. Outer coat cruftaceous, thin, brittle; inner membranaceous, with a ferruginous mark at the base. Embryo on one side: cotyledons ovate-lanceolate, accumbent, cutting one side of the albumen with a vertical cleft [k].

Native of North America. It was cultivated in 1640 by Mr. John Morrice, as appears from Parkinson [l]. Ray also had it in his little garden at Cambridge. It flowers in august and september.

6. Root annual. Stem about three feet high, round, smooth, hollow, branched, the branches spreading, swelling very much above the joints, patulous and sometimes decumbent. Leaves ovate-lanceolate, smooth above, sometimes spotted, underneath dotted with small glands, and often pubescent, edged with little hairs: petioles hairy underneath, and slightly rugged. Stipules nerved at the base, not terminated by any hairs, but sometimes subciliate. Spikes short, blunt, when the seeds are ripe drooping a little. Peduncles rugged with short glanduliferous hairs. Flowers of a greenish colour, (or pale red) on short peduncles, growing thickly together. Stamens a little shorter than the corolla. Style divided nearly down to the base. Seed heart-shaped, pointed, flat, with a depression in the middle, shining, sometimes obtusely triangular.

Mr. Curtis has fully discriminated this species from *Polygonum Perficaria*, of which Haller considers it as a variety, by the following circumstances. That usually grows by the sides of moist ditches; this prefers a more luxuriant soil, and is common on dunghills: it is not a variety however arising merely from this circumstance, Mr. Curtis having seen *Pol. Perficaria*, *Hydropiper* and this, all growing by the side of a stream, within six inches of each other. In its most common state, as described above, it is much larger than *P. Perficaria*, and its joints are more swelled; its stipules are much more strongly ribbed at bottom, and have no ciliæ; its leaves are broader, the veins somewhat deeper, and more strongly marked; the hairs on the edges of the leaves more visible, but particularly so under the petiole, to which they give a manifest roughness; in the uppermost leaves the under side is generally dotted with very minute glands, whilst in the lowermost it is covered with a kind of down, which, contrary to what Linneus asserts, is never in *Pol. Perficaria*, but in this species is always seen more or less predominant; the peduncles are thickly beset with little yellowish glands on short foot-stalks, which sometimes extend half down the plant, this appearance never, or very rarely occurs in *P. Perficaria*: the flowers are of a pale or greenish hue, and form thicker and larger spikes than in *P. Perficaria*, and in their mature state are so heavy as frequently to hang down a little: the style is divided nearly down to the germ, whilst in *P. Perficaria* it is divided only half way: in that species, the seeds are either triangular, or of a pointed oval shape, with a little convexity on each side; in this it is flat, with a depression on each side, it is also larger and broader; now and then a seed occurs, forming an unequal triangle, but these are very rare; whilst the triangular seed is most frequent in *P. Perficaria*.

Mr. Hudson first supposed this to be the *pensylvanicum* of Linneus, but afterwards considered it as a variety of *P. Perficaria*. Dr. Withering has made it a distinct species, under the name of *pallidum*. But it is now ascertained to be the same with the *lapathifolium* of Linneus; which he says is found in France; but he did not know that it is indigenous of England, and gave Bobart's name, in Ray's synopsis, to his *pensylvanicum*, which is a native of North America.

β. The variety with a red stalk and red flowers is often found on dunghills and in corn fields, and is like the true species in every respect excepting its colour, but the red of the flowers is not so bright.

γ. This not only differs in having its stalk spotted with red, but the spikes are much more slender, rather more so than those of *P. Perficaria*, of a red colour, but not so bright; the under side of the petiole is remarkably rough: and the seeds are smaller. It grows much in the same situations, and often with *P. Perficaria* in the ditches about St. George's Fields. When this variety grows in a rich soil, it is still as large as the species; but in a different soil and situation, as on the watery parts of Blackheath and Peckham Rye, it becomes much smaller, generally has its leaves white

[x] Curtis. Withering. [y] Woodville. [z] Smith. [a] Woodward. [b] Smith. [c] Withering. [d] Smith. [e] Linn. amœn. & suec. Gmel. Gunn. &c. [f] Gough in Withering. [g] Lightfoot. [h] Ray syn. [i] Parkinson. [k] Gærtner. [l] Hort. kew.

under-

underneath, and may be taken for *P. Perficaria*, if not attentively examined: its ſpotted ſtalk, and the roughneſs of the petioles, will however readily diſcover it.

3. The variety with leaves hoary on the under ſide, is found here and there in corn-fields and other places, where the ſoil is not very rich, and is obviouſly enough diſtinguiſhed.

Beſides theſe ſtriking varieties, it varies in ſize, according to the richneſs or poverty of the ground, and like *P. Perficaria*, the leaves are ſometimes ſpotted and ſometimes not.

Small birds are very fond of the ſeeds of this ſpecies and its varieties. The farmer ſhould carefully weed them from his dunghills[m].

7. Root perennial, creeping. Stems rooting, erect or floating, a foot and half or more in length, generally ſimple, or branching only in the lower part, round, hollow, commonly red, with the joints a little ſwelled, inveſted with tubular membranous entire ſtipules, which ſheath it above as well as below the inſertion of the foot-ſtalks. Leaves alternate, petioled, lanceolate with a heart-ſhaped baſe, acute, ſerrulate, and edged with hairs, harſh to the touch, deep or bright green, often ſpotted, ſomewhat waved. Pedunckes ſolitary or two together, erect, red, on one ſide flattened, and ſlightly grooved. Spikes bright red, at firſt pyramidal, afterwards ovate, thickly ſet, bracted at the baſe: at firſt they are terminating, but at length the ſtem is protruded beyond them. Bractes ovate, membranous, pointed. The flowers are on ſhort pedicels, and are compoſed of a roſe-coloured funnel-ſhaped calyx, divided into five obtuſe ſegments. Stamens only five, in the jaws of the calyx, of different lengths. Germ ſuperior, red, bearing two ſtyles, united and red a conſiderable way above the baſe, white in the upper part, tipped with red globular ſtigmas. Seed ovate, flattened on one ſide, pointed, gloſſy, brown or of a dark cheſtnut colour, with blunt corners[n].

This is the only European ſpecies in the *Perſicaria* diviſion of this genus, which has a perennial root; it may alſo be diſtinguiſhed from the others by the leaves being hollowed at the baſe, and fringed with hairs at the edges, they are alſo harſher to the touch, eſpecially when the plant grows out of the water; its ſtipules more cloſely ſurround the ſtalk, which has generally two ſpikes, neither of them perfectly terminating; theſe ſpikes are more pyramidal when young, and of a brighter red colour than any of the ſpecies related to it; when it grows in the water the whole plant becomes ſmoother, and is more diſpoſed to bloſſom; it is alſo obſerved that the ſtamens are longer than the calyx when the plant grows on land, and ſhorter when it grows in the water, but this is by no means conſtant[o].

Native of moſt parts of Europe, in ponds, ditches, rivers, and ſometimes on arable land. In water its long creeping roots run deep into the mud, throwing out whorls of fibres here and there, whilſt the leaves float upon the ſurface, and the beautiful ſpikes of flowers, in july and auguſt, are elevated above it. Here the leaves are ſmooth and of a bright green. Frequently however, as Ray obſerves, the roots are thrown out with the mud in clearing ditches, and if by that, or any other accident, the plant gets out of the water, the ſtems grow more erect, the leaves become narrower and hairy, and the flowers are more ſparingly produced[p].

As a weed, few plants are more pernicious, for the roots not only creep, but penetrate ſo deep into the earth, that they are ſeldom or never eradicated: but as it flowers rarely on arable land, it is a more local plant than ſome of the ſame genus, the ſeeds of which are either ſown, or introduced with manure. Waterfowl are fond of the ſeeds.

This ſpecies has the name of *amphibium*[q] from its growing both on land and in water. We may conclude that the latter is its natural ſituation, from its ſeldom producing the fructification in dry places.

[m] Curtis. [n] Curtis, Smith. [o] Curtis. [p] Engl. bot. [q] Curtis.

From its floating leaves the older botaniſts conceived it to be a *Potamogiton* or *Pondweed*. Ray, more attentive to the fructification, aſcertained it to be a *Perſicaria*[r].

Villars informs us, that it was ſuppoſed in Alſace to be injurious to cattle, but he is of opinion that it is rather uſeful to them, on account of its acid antiſeptic qualities. He remarks very juſtly, that all marſhy ſituations being unwholeſome, the plants which are moſt common there are accuſed of doing all the miſchief.

8. Stem round, marked with obſolete raiſed lines, erect, villoſe with cloſe-preſſed hairs, ferruginous. Branches alternate, hirſute, erect. Leaves alternate, acute, entire, ciliate, nerved, villoſe, erect, an inch long. Petioles dilated at the baſe, embracing, ſheathing. Stipules inflated, truncate, membranaceous. Spike terminating, drooping at the top, a ſpan long. Flowers ovate at bottom, cloſe at top, minute, opening in ſucceſſion. Bracte embracing, bearded, three-flowered: within this two other bractes involving each flower, lanceolate, entire. Corolla (or rather calyx) four-parted almoſt to the baſe, ſmooth: ſegments ovate, half a line in length; the three upper ones red, bent towards the lower ones, which are white. Filaments white, inſerted near the germ, a little ſhorter than the calyx, three ſhorter than the other two. Germ three-ſided, ſuperior. Styles two, awl-ſhaped, erect, the length of the filaments. Stigmas ſimple, blunt, patulous, white.

It is very nearly allied to *P. barbatum*, but the flowers have five ſtamens and two ſtyles; the ſpikes are filiform, quite ſimple, and very long; the ſtipules have ſhort ciliæ; and the leaves are ovate, not elliptic.—Native of Japan, near Nagaſaki; flowering in ſeptember and october[s].

9. The ſtipules are entire, ventricoſe, even ſheaths, much wider than the ſtem. Leaves lanceolate, revolute. Flowers in racemes.

Native of Siberia, where it was found by Gmelin[t]. Introduced in 1780, by Peter Simon Pallas, M. D. It flowers in july and is perennial[u].

10. Root annual, fibrous. Stem about two feet (or from one to three feet) high, branched, round, ſwelling above the joints, finally becoming very red, ſometimes creeping at bottom. Leaves of a yelloviſh green colour and ſmooth. Stipules ciliate, obſolelely nerved. Spikes terminating, linear or ſlender, looſe, nodding, (even before flowering.) Flowers pale red, (or green, but red towards the end) with glandular dots on the outſide. Stamens the length of the calyx. Anthers white. Style divided to the middle or deeper. Stigmas blunt. Seed ovate-acuminate, compreſſed, of a cheſtnut colour[v].

Dr. Stokes remarks, that the whole plant is ſprinkled with minute glandular dots, but even with the ſurface, and more obvious with a moderate than a higher magnifier, probably the ſeat of its very acrid property. Mr. Curtis adds, that theſe little cells or glands are more particularly obſervable on the calyx, which is accordingly more biting than any other part of the plant. From its hot acrid taſte it has the name of *Hydropiper*, *Water Pepper*, *Biting Perſicaria*, &c. Although the herb and calyx are ſo acrid, the ſeeds are inſipid and nutritive.

It is the only *Perſicaria* that has any pretenſions to be an active medicine: given in infuſion or decoction, it proves diuretic, and hence is uſeful in the dropſy and jaundice; the diſtilled water is recommended by Boyle in the ſtone and gravel[w]. The aſhes of the plant, mixed with ſoft ſoap, is a noſtrum for diſſolving the ſtone in the bladder; but it may be reaſonably queſtioned whether it has any advantage over other ſemicauſtic preparations of the vegetable alcali. Its acrimony riſes in diſtillation, and the diſtilled water, drank to the amount of two or three half pints daily has been found very effectual in ſome nephritic caſes[x].

Linneus informs, that the plant will dye woollen cloth of a yellow colour: and that all domeſtic quadrupeds reject it.

[r] Curtis. [s] Thunberg. [t] Linn. ſpec. [u] Hort. kew. [v] Curtis and Smith. [w] Curtis. [x] Withering.

It is native of moſt parts of Europe, and is found in great abundance in places that lie under water during the winter; flowering in ſeptember, generally a month later than *P. Perſicaria*. From this it differs principally in its leaves, ſpikes, form and ſize of its ſeeds. Its leaves are of a yellower hue, more undulated, and never marked with any ſpots; its ſpikes are ſlender, and when the ſeeds are ripe, bend and hang down; (Mr. Woodward obſerves that they droop even before flowering) the ſeeds are much larger, more acuminate, and of a cheſtnut colour; the ſtipules are very evidently ciliate, though Haller makes the want of ciliæ one of its ſtriking characters, and Linnæus calls them *ſubnullæ*. Notwithſtanding its obvious difference, Scopoli and Haller ſeem to entertain a doubt whether it be really diſtinct from *P. Perſicaria* and *minus*. There are indeed ſome intermediate varieties which bring them very near together, and perhaps juſtify ſuch ſuſpicion. A variety of the *Hydropiper*, ſcarcely differing in any other reſpect but its inſipidity, is now and then met with, in the ſame ſituation as we uſually find the true ſpecies [a].

11. Root ſimple, fibrous. Stem upright, ſometimes rooting at bottom, two feet (or from two to three feet) high, alternately branched, round, ſmooth, gradually thickened above the joints, often red. Leaves on very ſhort petioles, ſpreading and bent down, lanceolate, acute, quite entire, the edge and midrib ſlightly hairy, otherwiſe ſmooth on both ſides, having in general a large ſpot on the middle ſomewhat like a horſe-ſhoe, or rather creſcent-ſhaped. Stipules tubular ſheathing, ſhort, ribbed, terminated by long hairs, frequently full of a viſcid liquid. Spikes terminating or axillary, blunt, on ſmooth peduncles. Flowers of a bright roſe colour. Stamens the length of the calyx. Style divided to the middle into two, often into three parts. Seed ſhining, either ſubovate-pointed and ſlightly convex on one ſide, or three-ſided [b].

Dr. Withering remarks, that the leaves have very minute briſtles lying along the edge; that the common peduncles ſpring from the ſheathing ſtipules at the joints of the ſtem; that the flowers are three or four together, included in a membranaceous fringed ſheath, on ſhort pedicels of different lengths, which are again incloſed in membranaceous ſheaths; that the ſegments of the calyx are concave and unequal; the ſtamens ſometimes five or ſeven, with two anthers upon one filament.

This ſpecies is very nearly allied to the *lapathifolium*, but the ſtyle is divided only half way down, moſtly into two parts, and then the germ is a little convex on each ſide; but ſometimes into three parts, and then the germ is always triangular: the peduncles are quite ſmooth; the ſtipules are furniſhed with long ciliæ, particularly towards the top of the plant: and it differs much in the form of the ſeeds. It may be diſtinguiſhed from *P. Hydropiper* by the ſpikes, which in this are upright, and of an ovate ſhape more or leſs round [c]. Common in ditches and marſhes in moſt parts of Europe, flowering from july to ſeptember.

Its taſte is ſlightly acid and aſtringent. Woollen cloth dipped in a ſolution of alum obtains a yellow colour from this plant. Goats, ſheep and horſes eat it, cows and ſwine refuſe it [d].

Mr. Miller has mentioned this and the preceding ſpecies, together with *P. orientale* and *divaricatum*, under the name of *Perſicaria*, in the ſeventh edition of his Dictionary; he has alſo noticed the *Biſtorta*; and for *Fagopyrum* he refers to *Helxine*, which article is not to be found. In the eighth edition theſe are all omitted, the author having probably intended to bring them together under *Polygonum*, and having forgot it when he came to that article, as he has done in other inſtances.

12. Stems ſeveral, decumbent and rooting at the baſe, then becoming nearly upright, from a ſpan to a foot in height, little branched, ſomewhat thickened above the joints, ſmooth, reddiſh. Leaves ſmooth on their upper ſurface, with ſcarcely any appearance of veins. Stipules ſheathing, ciliate. Spikes ſlender, almoſt upright or a little drooping, proceeding from each joint. Flowers few, pale, red on the outſide, not dotted. Stamens the length of the calyx. Style bifid (or trifid) only at the top. Stigmas blunt. Seed ovate-acute or triangular, cheſtnut-coloured, nearly of the ſame ſize and ſhape as in *P. Perſicaria* [e].

Linnæus makes this a variety of *P. Perſicaria*. Ray and Hudſon conſider it juſtly as a diſtinct ſpecies, and after the accurate reſearches of Mr. Curtis, it can ſcarcely be doubted.

In height, this ſeldom exceeds a foot, whereas the *Perſicaria* often occurs a yard high; the ſtalk roots at bottom and is abſolutely procumbent, whilſt in *Perſicaria* it is always upright; the leaves are much narrower, approaching rather to linear than lanceolate, and on their upper ſurface have much leſs appearance of veins; the ſpikes, inſtead of being ovate or nearly round and upright, are ſlender and a little drooping; and the piſtil is ſlightly divided at top only.

It is very abundant in the watery parts of Tothill fields, Weſtminſter, with *Siſymbrium ſylveſtre*, in ſeptember [a]. It has been found on Putney-common by Dr. Goodenough; in a gravel-pit on Malvern-chace in Worceſterſhire, by Dr. Stokes; and on Coſtefy-common, near Norwich, by Dr. Smith.

13. Stem herbaceous, rufous. Stipules ſheathing, looſe, ſet with ſtrong briſtles almoſt the length of the ſtipule itſelf. Spikes long, with the flowers remote, three from each turbinate bractæ [f].

It differs from *P. filiforme* in having ſix ſtamens and three ſtyles; the leaves elliptic and acuminate; the ſpikes ſhorter, wider, often divided or ſeveral approximating, and in having the ſtipules awned [g].

Thunberg has diſtinguiſhed three varieties:

1. With the ſtem round, upright, ſmooth, purple; the branches alternate, erect, like the ſtem. Leaves petioled, alternate, elliptic, acuminate, entire, ciliate, villoſe eſpecially on the nerves, which are parallel, and the midrib is thick; they are three inches long, but the upper ones are leſs. Petioles dilated at the baſe, embracing, ſtriated, very ſhort. Stipules intrafoliaceous, cylindrical, hirſute, truncate, with upright awns, the length of the ſtipule. Spikes terminating, ſolitary or ſometimes two together, very ſeldom three, filiform, erect, imbricate, a finger's length. Bractes as in *P. filiforme*.

2. Has the ſtem roundiſh, little villoſe; branches alternate, ſtriated, erect, villoſe; leaves petioled, elliptic, acuminate, entire, ciliate, having parallel villoſe nerves, and two inches long or more. Spikes terminating, cylindric, divided, two or more together, an inch long. Seed dark, ſhining, ſmooth.

3. With a round, weak but upright, ſmooth ſtem; branches alternate, filiform, ſtriated, from upright ſpreading, ſmooth. Leaves alternate, elliptic, acuminate, entire, ciliate, ſmooth, ſprinkled with very frequent minute whitiſh dots, and an inch in length. Petioles, ſtipules and bractes as in *P. filiforme*. Spikes terminating, cylindric, ſolitary or two together, from three lines to an inch in length. Seed dark, ſmooth and ſhining.

All theſe varieties are found in Japan, in ditches and watery places. Thunberg found this ſpecies at the Cape of Good Hope, in Ceylon and Java.

Retzius alſo has three varieties. 1. From China, having the leaves and ſtipules hiſpid; the ſtipules and bractes ciliate. 2. From Malabar, ſmooth all over, the ſtipules only toothletted, the bractes quite entire. 3. From the Cape of Good Hope, ſmooth alſo all over, ſtipules and bractes ciliate.

14. Stem herbaceous, perennial, round, two feet high, manifold, nearly erect. Stipules ſheathing. Leaves quite entire, ſmooth, juicy, alternate, bright green. Flowers bright red, in long branching ſubterminating ſpikes. Calyx five-parted, converging. Style ſemitrifid.

Native of China near Canton. Introduced, according to the Kew catalogue, in 1776, by John Blake, Eſq.

[a] Curtis. [b] Curtis and Smith. [c] Curtis. [d] Linn.

[a] Curtis and Smith. [b] Curtis. [f] Linn. [g] Thunberg.

It is uſed in China to dye a beautiful blue or green colour. According to Thunberg, *P. chinenſe*, *barbatum* and *aviculare* are cultivated in Japan for the ſame purpoſe [k].

15. Root compoſed of many ſtrong fibres, growing in tufts. Stem jointed, eight or ten feet high, the lower part becomes woody, and as thick as an ordinary walking cane, of a fine green and a little hairy. Leaves alternate, often a foot long, and ſix inches broad in the middle, terminating in acute points, they have one ſtrong midrib, and ſeveral tranſverſe veins which run upwards towards the point; their ſurfaces are a little hairy, the upper of a bright green, and the under paler. Petioles broad, half embracing at their baſe. Flowers in cloſe terminating ſpikes, ſeven or eight inches long, hanging downwards. Stamens five, ſix or ſeven [l].

The ſtipules are deſerving of notice, being unuſual in their form, and making the ſtem look as if ruffled [m]. Thunberg remarks that the margin of the ſtipules is entire and revolute.

The calyx is five-cleft and equal. There is a yellow gland at the baſe of each ſtamen. Seed ſubglobular, compreſſed a little on each ſide, black, ſhining. Outer coat cruſtaceous, hard, ſomewhat brittle: inner of a ruſty red colour, with a brown ſpot at the baſe. Albumen farinaceous. Embryo on one ſide, bowed, inverted, yellowiſh [n].

There is a dwarf variety of it, and another with white flowers; it has been obſerved to vary alſo in point of hairineſs [o]. Linneus remarks that the Eaſt Indian plant is far more hairy than that from the Levant. It flowers from july to october, or till the froſts in autumn come on; ſoon after this the plant decays and dies [p]. It was cultivated in 1707, by the Dutcheſs of Beaufort. The variety with white flowers was introduced in 1781, by Monſ. de Wevelinchoven [q].

The ſeeds were firſt ſent to Europe by Tournefort, who ſaw it growing in the Prince of Teffis's garden in Georgia, and afterwards in the garden of the monks of the Three Churches near mount Ararat. They cultivate this plant there, not only for the beauty of the flowers, but for its medicinal qualities, which are the ſame with thoſe attributed to our common ſpecies [r].

16. This has the appearance and habit of *Pol. Perſicaria*, but all the parts are larger and ſtiffer. Stem branched, angular. Leaves acuminate with the keel very rugged underneath. Stipules truncate. Peduncles rugged, with ſtiffiſh hairs ſecreting a clammy juice from the top. Spikes ſubracemoſe, with pedicelled florets.

Native of Pennſylvania, where it was obſerved by Kalm [s].

Ray's *Perſ. mitis foliis pallidioribus* has been ſuppoſed to be the ſame with this; but that is now aſcertained to be the ſame ſpecies with *Pol. lapathifolium* of Linneus.

17. According to Linneus, the Sea Knot-graſs is ſo nearly allied to the common ſort as ſcarcely to be diſtinguiſhed from it. The flowers are in ſouts. Stem flatter on one ſide. All the parts larger and harder. Leaves ovate, coriaceous, evergreen, turning blue in drying. Stem ſhorter, hard, perennial.

Villars deſcribes it as hard, robuſt, thick and ſomewhat woody; the ſtems reddiſh; the ſtipules very large; the leaves thick and in a manner fleſhy; it is very diſtinct from the common ſort.

Deſfontaines ſays that the ſtems are proſtrate, branched, knobbed; the leaves glaucous, ſomewhat fleſhy, coriaceous, elliptic, quite entire, with the margin reflexed underneath. Stipules membranaceous, white, ſheathing. Flowers axillary, three to five at a joint. Calyx five-parted; ſegments elliptic, with a white margin, but greeniſh in the middle. Stamens eight, ſhorter than the calyx. Styles three.

According to Krocker, the calyx (or corolla as he calls it) is bright purple; the ſeeds three-ſided and black. About the ſolſtice, bladders grow on it full of a red juice, which the Poles uſe to make an elegant red dye; hence Schwenkfeld calls this plant *Pol. coccygerum*.

Native of the ſandy coaſts of the Mediterranean ſea, the Levant and Virginia.

Our Sea Knot-graſs, is not this, but a variety only of the next.

18. Root annual, branched, ſomewhat woody, taking ſtrong hold of the earth, of an aſtringent taſte. Stems many, generally procumbent, divaricating, branched, leafy, round, ſtriated, thicker at the joints, and ſeparating there when pulled. Leaves alternate, elliptic-lanceolate, (or varying from ovate to lanceolate and even linear) attenuated at the baſe, ſmooth except at the edge where they are ſomewhat rugged. Stipules acute, ſcariole, with few remote nerves, ſheathing. Flowers axillary, in cluſters, two or three together, pedunculed, ſmall but not inelegant, variegated with white green and blood red. Stamens eight ſhorter than the calyx. Styles three, very ſhort. Seed three-ſided, ſhining, blackiſh [t].

Dr. Withering remarks, that the peduncles are ſhort, but two of them longer than the third: that the calyx is double; the outer with five lanceolate ſegments incloſing the three florets, the inner incloſing only the third floret and ſometimes the rudiment of a fourth. Deſfontaines ſays, one, two or three flowers proceed from the ſame ſheath.

This is one of the moſt common plants, eſpecially in a ſandy or gravelly ſoil, on banks, by roads and paths, and in corn fields; it frequently covers much ground, where the natural graſs has been deſtroyed. Where it grows ſingly in a rich or newly thrown up ſoil, a ſingle plant will often cover the ſpace of a yard or more, and the leaves are then broad and large; but when it grows very thick together, it is in every reſpect ſmaller [u]. On our ſandy coaſts it is found with large oval thick leaves, approaching to *Pol. maritimum*, but not perennial [w]. Dr. Smith has ſatisfactorily diſtinguiſhed our maritime variety from the true *maritimum* of Linneus and other foreign botaniſts. The latter has a ſhrubby perennial ſtem; wide elliptic glaucous leaves, ſcarcely rugged at the edge; but it differs particularly in having numerous approximating nerves to the ſtipules.

This plant has the generic name *Polygonum*, from the abundance of knots on the ſtem; the trivial name *aviculare* from the gratefulneſs of its ſeeds to ſmall birds; the Engliſh name *Knot-graſs*, from the knottineſs of the ſtem, and becauſe it is eaten by cattle, many ſuch plants having obtained the name of *Graſs*, though they bear no ſimilitude to real graſſes. Hogs eat it with great avidity, and hence it is known in many counties by the name of *Hogweed*. All other domeſtic quadrupeds are ſaid to eat it. The ſeeds are uſeful for every purpoſe in which thoſe of Buckwheat are employed; but they are much ſmaller.

This plant has been conſidered by old writers as poſſeſſing ſome medical virtue, particularly as an aſtringent, and was recommended in diarrhœas, dyſenteries, and hæmorrhages; but in the preſent practice it is juſtly ſuperſeded by more efficacious medicines [x].

Thunberg informs us, that this ſpecies, the *chinenſe* and *barbatum* are cultivated in Japan for dyeing [y].

19. This is an annual plant, native of Philadelphia, whence the ſeeds were ſent by Kalm to Sweden.

20. Root annual, ſmall, fibrous. Stem a foot high, with alternate branches towards the top, ſubdivided into a flowering panicle. Stipules ſolitary, ſheathing, wider upwards, entire, truncate, not cloven. Leaves linear, ſmooth. Filiform very narrow ſpikes terminate the panicle, imbricated with ſheathing turbinate truncated bracteæ: from each ſinus ariſes a ſolitary, capillary peduncle, jointed at the baſe, coloured, one-flowered. Calyx fleſh-coloured, five-parted, with the

[k] Loureiro. [l] Mill. fig. [m] Curtis. [n] Mill. fig. [o] Hort. kew. [p] Mill. fig. [q] Linn. ſpec. [r] Curtis. [s] Gærtner. [t] Smith, Curtis. [u] Curtis and Fl. ruſt. [w] Curt. With. Fl. ruſt. [x] Travels, 4. 90. engl. edit. [y] Thunb.

bottom looſer than in *P. avicularе*. Native of Canada, where it was found by Kalm [a].]

21. Root perennial, creeping, compoſed of many ſtrong woody fibres. Stems about three feet high, divided into many confuſed branches, which are generally bent at each joint. Leaves about four inches long, and half an inch broad, ſmooth, of a light green, and ending in acute points. Flowers white, in looſe ſpikes, branching out from the end of the ſtems [b].

[This beautiful ſpecies, ſays Villars, riſes to the height of two or three feet. Stems branching and ſolid. Leaves wide, reddiſh and a little villoſe, with a ſheathing membrane red at their baſe. Flowers of a whitiſh red, divided into four, five or ſix open ſegments. Stamens from five to eight. Piſtils three.—Native of Siberia—Switzerland, Corſica, Dauphin[e], Piedmont; if the different authors quoted mean the ſame plant.—Cultivated in 1759, by Mr. Miller [c].

22. This very much reſembles the preceding. It is perennial and a native of Siberia [d]. Murray has deſcribed it at length in the Gottingen Commentaries.

23. This was found in Barbary by Shaw.

24. Stem four-cornered, ſmooth, even, grooved, decumbent. Branches alternate, like the ſtalk, ſpreading very much. Leaves alternate, ſubcordate, ovate, acuminate, entire, ſmooth, an inch and half long. Petioles dilated at the baſe, ſheathing, ſtriated. Stipules biſid, membranaceous, generally longer than the petiole: ſegments lanceolate, ſetaceous. Flowers terminating, panicled on pedicels, ſubtrichotomous. Peduncles and pedicels four-cornered, grooved, ſmooth (ſcarcely rugged) erect. Calyx ſubglobular, five-parted, whitiſh. Filaments eight, erect, the length of the corolla. Style erect, ſimple at the baſe, but quickly trifid, white, of the ſame length with the ſtamens. Stigmas three, revolute, white [e].

According to Loureiro, the ſtem is herbaceous, ſuberect, three feet high, round, weak: the ſtipules lanceolate, ſmooth, ſheathing: the leaves red at the edge, and ſomewhat curling: the flowers in ſubdivided, ſpreading racemes.

Linnæus ſays, the ſtem is flexuoſe; the peduncles hiſpid, commonly trifid at the top; the flowers capitate; the ſtipules wide, quite entire, not ciliate, ovate; the heads of flowers roundiſh and few.—Native of the Eaſt Indies, China and Japan.

It is cultivated in China and Japan for dyeing, and produces a beautiful blue colour, much like that from Indigo. The leaves are dried, then pounded, and made into ſmall cakes: with theſe, it is ſaid, they dye linnen, ſilk and cotton. When they boil them for uſe, they add aſhes: the ſtronger the decoction is made, ſo much the darker is the blue colour which is obtained, and the contrary [f].

25. Stem decumbent, branched, very ſhort. Branches alternate, four-cornered, the corners ſharp, prickly backwards, ſmooth, almoſt upright, a foot long. Leaves alternate, but oppoſite to the branch, entire, ſmooth, pale underneath, an inch long. Petioles unequal, commonly ſhorter by half than the leaf, prickly, ſpreading very much. Stipules biſid, a little inflated, quite entire, very ſhort. Flowers terminating, collected together into a ſpherical head. Bractes ovate, acute, entire. Stamens ſeven. Piſtils three. Seeds black, with equal, blunt, entire angles [g].

Linnæus remarks, that it ſometimes climbs up ſhrubs.

Native of North America; alſo of Siberia and Japan.—Cultivated by Mr. Miller in 1759 [h].

26. Stem decumbent. Branches alternate, angular, ſmooth, from upright-ſpreading: angles unequal, ſeveral, prickly backwards. Leaves alternate, acuminate, villoſe and ſtrigoſe, unequal, about an inch in length. Petioles prickly, one fourth of the length of the leaf. Stipules truncate, hirſute, ciliate. Flowers on the branchlets alternately aggregate. Bractes ciliate. Stamens ſeven, with three capillary ſtyles. Stigmas globular. Seeds ſmooth and even, with the angles entire [i].

According to Clayton, the ſtem is ſcandent [k].

Native of Virginia and Florida; alſo of Japan.

27. This is a ſmalliſh plant ſcarce more than a ſpan long. The ſtem is decumbent and flexuoſe, ſmooth, thick, round, reddiſh, and branching at the baſe: the branches are alternate, variouſly bent, and axillary: the ſtipules ſolitary, ſheathing, truncated, and of a pale brown: the leaves linear-lanceolate, haſtate, narrowed at the baſe, ſhortly footſtalked, fleſhy, punctated, almoſt without veins, except the rib, and very ſmooth: ſpikes terminal, emerging from the extreme axils, conglomerate, eight or ten-flowered: peduncles cornered, with very ſhort bending pedicels. Corolla five-petalled, greeniſh-white, petals ovate, concave: ſtamens eight, filaments ſubulate. Piſtils three. Germ ſingle, red. Styles three. Stigmas clavate [l].

28. This reſembles *P. ſagittatum* and *arifolium*. Stem angular, with ſmall recurved prickles; as have alſo the petioles. Stipules not ſheathing, but ſpreading, ovate or roundiſh, quite entire. Leaves a little ſinuate at the baſe, more in breadth than length, ſometimes peltate. Peduncles at the the top of the ſtem, few-flowered, prickly [m].

Stem ſhrubby, ſcandent but without tendrils, fifteen feet high, branched, with many inverted prickles on it; as there are alſo on the petioles and peduncles. Leaves quite entire, ſmooth except on the ribs and margin, which are prickly. Petioles long, alternate. Flowers whitiſh or blue, in ſimple, ſolitary, ſhort, terminating ſpikes. Calyx membranaceous, bell-ſhaped, five-parted; the parts ovate. Filaments eight, very ſlender, faſtened to the middle of the tube. Style trifid. Seed roundiſh, black, ſhining.

There is a variety, ſimilar in habit, with a blue flower, which has a calyx and a corolla, both five-cleft, but the latter fleſhy and almoſt cloſed.

It is uſed medicinally for reſolving tumours, and in a waſh for the itch: œconomically frequent at the table; mechanically for ſoftening ivory and bones [n].

Native of the Eaſt Indies, Japan and Cochinchina, in hedges.

29. Root annual. Stem herbaceous, two feet high. Leaves quite entire, ſmooth, few, alternate, on long petioles. Flowers white, on many-flowered, axillary and terminating peduncles; with oblong, curved common involucres. Calyx bell-ſhaped, five-parted. Stamens eight. Styles three. Seed three-ſided, red [o]; cordate at the baſe, pyramidal-mucronate at the top, toothed or repand at the angles, of a dirty aſh-colour: outer coat cruſtaceous; inner membranaceous, with a brown mark at the baſe: embryo central; cotyledons leafy, tranſverſely flexuoſe [p].

Native of Tartary and China.—Cultivated in 1759, by Mr. Miller [q].

30. Root annual, fibrous. Stem upright, ſomewhat flexuoſe, round, ſmooth, leafy, ſucculent, either wholly green or more frequently tinged with red, from a foot to eighteen inches in height, ſometimes quite ſimple, but more often having ſmall branches coming out ſingly and alternately from the axils. Leaves ſmooth, ſucculent, dark green, quite entire, ſometimes waving on the edge; the lower ones are on petioles two inches in length, but theſe become gradually ſhorter till the upper leaves are ſeſſile. Stipules ſhort, quite entire, awnleſs. Racemes of flowers axillary and terminating, panicled, upright, ſhorter than the leaves, on ſlender peduncles an inch or more in length. The flowers make a handſome appearance, and are either quite white, or tinged with red; with age they become more red. Eight little glands ſurround the baſe of the germ. The eight filaments are of the ſame length with the calyx; four between the glands and the germ, and four between them and the calyx. The ſeed is naked, being ſcarcely covered at

[a] Linn. ſpec. [b] Linn. ſuppl. [c] Thunb. jap. [d] Mill. dict. ed. 7. [e] Thunb. jap. & Trav. 4. 91. engl. ed. [f] Hort. kew. [g] Thunberg. [h] Linn. ſpec. [i] Linn. [k] Loureiro. [l] Marr. in comm. gott. [m] Idem. [n] Gærtner. [o] Hort. kew.

the

the base, it is a three-sided pyramid, with the angles straight not sinuated [a].

Buck-wheat is supposed by some to have come originally from Africa, but it is generally allowed that we derived it from Asia. In China the flour of Buck-wheat is frequently made into the form of cakes [b]. So it is also in Japan [c]. It is not indigenous of Europe, though it has found its way into most of the European Floras, and occurs on dunghills and about cultivated fields. In England it is certainly not indigenous, nor will it bear the rigour of our winters. It flowers in july and august.

Besides *Buck* and *Buck-wheat* (or *Beech-wheat*, from the similitude of the seed, in form, to Beech-mast) it has the appellations of *Brank*, *Crap*, and *French Wheat*. Gerarde has also the name of *Bullimong* [d]. In French it is called *Bled noir* or *Sarrazin*.

The flour of Buck-wheat is made into thin cakes, called crumpits, in some parts of England, and it is supposed to be nutritious, not apt to turn acid upon the stomach [e].

The seed is excellent for horses, either whole or broken, mixed with bran, chaff or grains. A bushel goes farther than two bushels of oats, and mixed with at least four times as much bran, will be full feed for any horse a week. Four bushels of the meal, put up at four hundred weight, will fat a hog of sixteen or twenty stone in three weeks: giving him afterwards three bushels of Indian Corn or hog Peas, broken in a mill, dry, with plenty of water. Eight bushels of Buck-wheat meal will go as far as twelve bushels of barley meal [f].

Mortimer recommends, to feed the plant with milch cows just before it blossoms, and it is said to flush them with milk.

Sheep feeding on the green herb are said to become unhealthy. According to the Swedish experiments. Cows, sheep and goats eat it, swine and horses refuse it.

The seeds are excellent food for poultry.

A field of Buck-wheat furnishes a rich repast for Bees late in the season; hence Mons. Duhamel advises to move the hives in the autumn, to a situation where plenty of this plant is sown [g].

31. Root annual, fibrous, of a brown colour. Stem twining, often to the height of six feet; when destitute of support procumbent and about a foot in length, angular, striated, sometimes a little rugged, branched alternately towards the top. Leaves perfectly entire, smooth, petioled, on the lower part of the stem standing singly, on the upper part two or three together, the lowermost often coloured. Dr. Withering remarks, that their angles at the base are sometimes truncate. Stipules small, forming a sheath round the stem. Racemes peduncled, interrupted, having small leaves on them. Dr. Withering, who calls them flowering spikes, observes that they are longer than the leaves. Flowers in bundles, nodding, white, on the outside green and purple, the three outer segments bluntly keeled, and not having the keel dilated. The eight filaments are fixed into the bottom of the calyx, and are very short and tapering: anthers purple, twin. Style very short, not quite so long as the stamens; stigma forming a little head, composed of three lobes. Seed three-sided, very black [h].

Native of most parts of Europe, Siberia, Japan, &c. in corn fields, gardens and hedges: flowering from june to september.

The seeds afford excellent food for small birds [i]. They are indeed as good for use as those of the preceding species, are produced in greater quantity, and the plant bears cold better. According to the Swedish experiments, cows and goats eat it; sheep, swine and horses refuse it. Dr. Stokes says, a horse will eat it [k], and if sheep will eat the preceding, and goats eat both this and that, we may conclude that sheep will not refuse this. Very little dependance is to be placed on these observations in many cases.

32. Root tuberous, somewhat fleshy, fibrous, white. Stem climbing at bottom, flexuose, even; twining at top, filiform, smooth. Leaves alternate, petioled, subcordate, ovate, acuminate, entire, smooth; the lower ones an inch and half wide, subtruncated at the base, two inches long; the upper ones more cordate and smaller. Flowers panicle-racemed from the axils of the leaves. Panicle compound, spreading very much. Peduncles and pedicels capillary, divaricated. Bractes ovate, acute, entire.

It differs from *P. dumetorum*, which it resembles very much, in having minute blunt flowers, in a branched, racemed, very spreading panicle [l].

Native of Japan, where the root is esteemed as a cordial, and is used for that purpose raw; but it is said to taste best when roasted in the embers [m].

33. Root annual. Leaves cordate, with the lobes of the base rounded. Stem not striated. Panicle of a compound raceme, alternately bifarious. Anthers white [n].

Haller says, the principal difference between this species and *Pol. Convolvulus*, consists in the three membranaceous wide much elevated white wings of the three leaves which include the seed. It grows higher. Some of the flowers are in racemes from the axils, others are disposed in rather large many-flowered, spikes, hanging on long peduncles. The stems are striated.

According to Kroeker, the stem is longer and more twining than in *P. Convolvulus*, and it is not striated. The lobes at the base of the leaves are more rounded. The flowers are rather panicled than racemed. The segments of the calyx are wider, winged, whitish and membranaceous.

Leers remarks, that this as well as *P. Convolvulus* has one short style, with three globular approximating stigmas; that the stem is very slightly striated; and that the membrane on the three outer segments of the calyx is waved.—Native of Germany, Switzerland, France, and Siberia.

34. Stems round, red, succulent, winding itself round trees and shrubs, seven or eight feet high, with alternate leaves towards the top, on petioles a quarter of an inch long, they are grass green, juicy, smooth, thick, an inch and a quarter long, and one inch over at the base. The flowers come out from the upper axils, very many, in spikes three inches long, on a very short peduncle, they are round, flat, swelled out in the middle, and green, having a thin white membrane round them, like a Parsnep seed: when the seed is ripe these membranes become somewhat larger, and the protuberant part in the middle turns brown [o].

Linneus observes, that the base of the petioles in this species, *Pol. dumetorum* and *Convolvulus* is perforated underneath by a pore.

Native of America.

It was cultivated in 1759 by Mr. Miller, is perennial, and flowers in august and september [p].

35. Stem herbaceous, simple, four-cornered, upright, slender, a foot and half high. Stipules embracing. Leaves ovate-lanceolate, quite entire, smooth, alternate, subsessile. Flowers terminating, pale red. Calyx bell-shaped, five-cleft. Seed three-sided, naked. Native of China.

36. Stem herbaceous, one foot high, nearly upright, simple. Stipules blunt, ciliate. Leaves lanceolate, quite entire, smooth, alternate, subsessile; having a sharp pleasant smell, and a hot biting taste like pepper. Flowers small, red, in long stiff spikes. Calyx funnel-form, five-parted. Filaments shorter than the corolla. Styles three, the length of the corolla, with very small globular stigmas. Seed subtrigonal, acuminate at each end, within the shrivelled calyx.

Native of Cochinchina, in moist places, and cultivated all over the country, as an excellent sauce both for flesh and fish [q].

PROPAGATION AND CULTURE.

3. Biſtort may be propagated by planting the roots in a moiſt ſhady border, either in ſpring or autumn.

6, 7, 10, 11, 12, are common weeds, not admitted into gardens.

15. Oriental Perſicaria riſes from ſcattered ſeeds much better than when ſown: but where they are ſown, it ſhould be in autumn, ſoon after the ſeeds are ripe: ſown in the ſpring they rarely ſucceed, or if ſome plants come up, they ſeldom grow ſo ſtrong. In the ſpring tranſplant them into the borders of the plantation or flower garden, giving them room. At the beginning of july prune off the ſide ſhoots, to make them advance in height, and preſerve them within compaſs: when they are pruned up to five or ſix feet, they may then be permitted to ſhoot out ſide branches. This plant delights in a rich moiſt ſoil.

[It is diſtinguiſhed no leſs for its ſuperior ſtature than the brilliancy of its flowers; it will frequently grow to the height of eight or ten feet, and become a rival to the Sun-flower. It is commonly ſown in the ſpring with other annuals; thinning the ſeedlings, when they appear, ſo as to ſtand a foot apart. It requires very little care, and will bear the ſmoke of London better than many other plants[1].

30. Buck-wheat ſeems to have been cultivated time out of mind in England. Gerarde, in 1597, informs us, that it is very common about Namptwiche in Cheſhire, "where they ſow it as well for food for "their cattle, pullen (or poultry) and ſuch like, as to "ſerve inſtead of a dunging. It groweth likewiſe in "Lancaſhire, about London, as alſo in Kent and "Eſſex."

It is by no means ſo common a crop with us as in many parts of the continent: the county of Norfolk grows more of it than any other. One principal uſe of it is for cleaning foul land, and as a manure, ploughed in when fully grown[2]. In a dry ſummer it is good fodder; and as a crop it will produce an equal quantity with oats, and ſell for more money. The farmer may have any crop after it, eſpecially wheat.

Winter Tares may be ſowed in ſeptember, and mowed off as ſoon as convenient in the ſpring; then Buck-wheat may be ſowed the ſecond week in may, and ploughed in when in flower, which will be about the ſecond week in july; laſtly, ſow Wheat, each on one earth. Or ſeed Turnep may be rolled in, harrowing with a light buſh harrow.

Making Turneps ſucceed Buck-wheat ploughed, is good huſbandry on light lands, where there is a difficulty in procuring manure; and upon heavy ſtrong lands, that have been long under the plough, with two crops and a fallow. A heavy crop of Buck-wheat is certain to be procured on ſtrong clay land, well pulverized, in the month of june, provided the ſummer proves tolerably dry, after the ſeed is ſown.

There is no better way of laying down light lands to graſs, than in the month of june to let Buck-wheat with graſs ſeeds follow Swediſh Turneps. Twelve pounds of white Clover and eight pounds of yellow Trefoil may be ſown on an acre. One buſhel is ſufficient to ſow an acre; but ſome go as far as two buſhels[3].

After it is mown, it muſt lie ſeveral days, till the ſtalk be withered, before it be houſed. It is in no danger of the ſeeds falling, nor does it ſuffer much by wet. It yields fifty or ſixty buſhels upon an acre in good land[4]. Worlidge ſays, it was much ſown in his time in Surrey[5].

Claſſ. 19. 4. Syngeneſia Polygamia Neceſſaria.

Nat. order of *Compoſitæ Oppoſitifoliæ*. *Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common exterior* ſpreading, larger, four or five-leaved, with ovate leaflets; *ſuperior* eight or ten-leaved, with boat-ſhaped, erect leaflets.

COR. *Compound* radiate. *Corollets* hermaphrodite many in the diſk: female five or ten in the ray.

Proper of the hermaphrodite funnel-form, five-cleft: of the female ligulate two or three-toothed.

STAM. in the hermaphrodites, *filaments* five. *Anther* cylindric, tubular, a little longer than the corolla.

PIST. in the hermaphrodites: *Germ* very ſmall; *ſtyle* filiform, the length of the ſtamens; *ſtigma* blunt. In the females, *Germ* ovate, biggiſh. *Style* filiform, the length of the tube. *Stigmas* two, acute.

PER. none. *Calyx* unchanged.

SEED in the hermaphrodites none; in the females ſolitary, obovate, gibbous, ſomewhat angular inwards, naked.

REC. chaffy, convex, imbricate: *chaffs* ovate, obtuſe, the length of the florets, concave.

OBS. *In* Tetragonotheca *and* Wedelia *the exterior calyx is four-leaved.* Wedelia *differs from the reſt in having the petals of the ray emarginate, and the pappus of the ſeeds flat and ten-toothed.*

ESSENTIAL CHARACTER.

Cal. exterior four or five-leaved: interior ten-leaved, the leaflets concave. *Corol* none. *Recept.* chaffy.

DESCRIPTIONS, *&c.*

1. This has an abiding root, which ſends up many tall ſtalks, ſometimes near ten feet in height. Leaves large, angular, ſinuated, of a deeper green than thoſe of the ſecond ſort. Flowers of a paler yellow colour and ſeſſile. They appear late in the autumn, and are not followed by ſeeds in England. It grows naturally in ſeveral parts of North America. [Cultivated by Mr. Miller in 1768.]

2. Root perennial, running deep in the ground, ſending up in the ſpring many ſtalks in proportion to their ſize; theſe in moiſt good ground will riſe near ten feet high. Leaves large, angular, ſinuated, eight or ten inches over, of a light green. Stems terminated by a cluſter of yellow flowers ſitting cloſe, having very ſhort foot-ſtalks; each having five female ligulate

florets in the border, and ſeveral hermaphrodite florets in the middle, encompaſſed by a double calyx, the outer having five ſpreading leaves, the inner ten erect ones. The flowers appear in october too late to produce ſeeds here. The ſtalks decay in winter.

Native of Virginia, whence Mr. Miller received the ſeeds. [It was cultivated in the Chelſea garden in 1712[a].

Petiver named this plant *Uvedalia* in honour of Robert Uvedale, LL. D. of Trinity College in Cambridge. He lived at Enfield, and cultivated a garden there, which appears to have been rich in exotic productions[b].]

3. Root perennial. Stems about two feet and a half high, branching towards the top. Leaves large, oblong, rough, cloſely embracing; they are a little ſinuated on their edges, and are covered with ſmall hairs. Each of the branches has one large yellow flower at the end, ſhaped like a Sun-flower; before it expands, covered with the inflated four-cornered calyx. The ſeeds rarely ripen in England; and the ſtems periſh in autumn.

Native of Carolina. [Dillenius ſays, that it flowered from Carolina ſeeds, at the beginning of ſeptember 1726, in the Eltham garden. It had the name of *Tetragonotheca*, from its four-cornered calyx[c]. Linneus and Aiton make it a native of Virginia; and Linneus (in his ſpecies) refers to *Gron. virg.* 128. Dillenius refers only to Ray, *hiſt.* 3. *app.* 244. *n.* 7.

4. Root annual (or biennial.) Stem herbaceous, from two to ſix feet high, round, the thickneſs of a finger, rugged, preſſed cloſe, dotted with oval convex browniſh dots, ſparingly branched at top. Leaves like thoſe of *Coreopſis cernua*, embracing, acute, rugged on both ſides. Peduncle terminating, from the forking of the future plant, erect, ſolitary, one-flowered, leafleſs. Common perianth five-leaved, ſpreading, very large: leaflets cordate, ſubſerrate, gaping at the baſe. Corolla yellow: florets of the ray wide, three-toothed, blunt, pubeſcent at the baſe; thoſe of the diſk ſtanding out, pubeſcent at the baſe. Anthers teſtaceous, longer than the corolla. Stigmas ſtanding out, revolute, in the diſk as well as the ray. Seeds oblong, naked. Receptacle convex, chaffy. It has the appearance of *Coreopſis cernua*.

Native of Abyſſinia[e]:—of Africa, where it was found by James Bruce, Eſq. Introduced in 1775. It flowers here in april and may[f].

5. This is a ſhrubby ſcandent plant, with round ſmooth woody ſlender branched brachiate ſtems. Leaves ovate, acute, ſlightly ſerrate, rugged on both ſides, on a ſhort petiole, oppoſite, on the younger branches. Peduncles one-flowered, ſolitary, ſubterminating, new branchlets ſpringing out at their baſe. Flowers yellow, leſs than an inch in diameter. The outer chaffs are larger, and ſeem as if they were the inner leaflets of the imbricate calyx; but on a more accurate inſpection it is plain that they are the chaffs of the radical florets, and that each floret has its proper chaff[g].

It is very nearly allied to the third ſpecies, although the ſeed has a plane ten-toothed crown[h].

The outer calyx is four-leaved only. It differs from the other ſpecies, in having the petals of the ray emarginate, and a plane ten-toothed pappus to the ſeeds[i].—Native of Carthagena in New Spain.]

PROPAGATION AND CULTURE.

1, 2. Theſe plants are propagated by ſeeds, procured from the countries where they grow. If they arrive in the ſpring, and are then ſown, the plants ſeldom come up until the following ſpring: whereas if they could be obtained in november, and were immediately ſown, the plants would appear the following ſpring.

Sow the ſeeds in a bed of light ground in the open air; when the plants come up, thin them, and keep them clean till the following autumn; then take the roots up carefully, and tranſplant them where they are to remain; allowing each plant at leaſt three feet. Keep them clean, and dig about them every ſpring.

3. Sow the ſeeds as directed for the two preceding, and manage it in the ſame manner. The roots will abide through the winter in the open ground, in a warm ſituation. In very ſevere weather they ſhould be covered with rotten tan or peas haulm. They will live three years, but as they do not increaſe it will be beſt to procure ſeeds from abroad annually.

Forſk. prodr. n. 437.
Fronds pinnatifid even, pinnas linear blunt waved diſtant, runners rooting ſcandent.
35. Polypodium pectinatum.
Lin. ſpec. 1545. *Reich.* 4. 413. *Forſk. ægypt.* 7. 185. *Pet. fil.* 31. *t.* 7. *f.* 14. *Plum. amer.* 26. *t.* 37. *fil.* 64. *t.* 83.
Fronds pinnate lanceolate, lobes approximating enſiform parallel acute horizontal, root naked.
36. Polypodium taxifolium. *Yew-leaved Polypody.*
Lin. ſpec. 1545. *Reich.* 4. 413. *Pet. fil.* 35. *t.* 14. *f.* 1. *Plum fil.* 69. *t.* 89.
Fronds pinnate, lobes approximating enſiform parallel acute aſcending, root rough-haired.
37. Polypodium ſtruthionis. *Oſtrich-feathered Polypody.*
Lin. ſpec. 1545. *Reich.* 4. 413. *hort. cliff.* 475. *Pet. fil.* 30. *t.* 3. *f.* 8. *Plum. fil.* 64. *t.* 82.
Fronds pinnate, lobes approximating enſiform repand horizontal.
38. Polypodium ſquamatum. *Scaly Polypody.*
Lin. ſpec. 1546. *ſyſt.* 935. *Reich.* 4. 413. *Plum. fil.* 61. *t.* 79.

Fronds pinnatifid rugged, pinnas lanceolate distant horizontal quite entire.

39. Polypodium loriceum.
Lin. spec. 1546. *Reich.* 4. 413. *Laur. cochinch.* 674. *Pet. fil.* 27. 28. *t.* 7. *f.* 10. 12. *Plum. fil.* 60. *t.* 78.

Fronds pinnatifid even, pinnas lanceolate distant horizontal repand.

40. Polypodium alatum. *Winged Polypody.*
Lin. spec. 1546. *Reich.* 4. 414. *Pet. fil.* 37. *t.* 7. *f.* 13. *Plum. fil.* 65. *t.* 84.

Fronds pinnatifid even, pinnas oblong distant toothed.

41. Polypodium ellipticum. *Elliptic-leaved Polypody.*
Lin. syst. 935. *Thunb. jap.* 335.

Fronds pinnatifid, pinnas elliptic even entire, shoot creeping.

42. Polypodium aureum. *Golden Polypody.*
Lin. spec. 1546. *Reich.* 4. 414. *hort. cliff.* 475. *Plum. amer.* 25. *t.* 35. *fil.* 59. *t.* 76. *Raii suppl.* 56. *Pet. fil.* 15. *t.* 7. *f.* 8. *Mor. hist.* 3. 563.

Fronds pinnatifid smooth and even, pinnas oblong distant, the lowest patulous, the terminating one very large, fructifications in rows.

43. Polypodium quercifolium. *Oak-leaved Polypody.*
Lin. spec. 1547. *Reich.* 4. 414. *fl. zeyl. n.* 382. *Hill. anat. t.* 10. *Baub. pin.* 359. *Mor. hist.* 3. 564. *f.* 14. *t.* 1. *f.* 15. *Pet. mus.* 794. *Raii suppl.* 57. *super. Clus. exot.* 88. *t.* 89. *Pis. mant.* 195. *Rumph. amb.* 6. 78. *t.* 36. *Rheed. mal.* 12. 23. *t.* 11.

Barren fronds sessile shorter blunt sinuate, fruiting fronds alternate-pinnate lanceolate.

3. *Frond trifoliate: peduncle with three leaflets.*

44. Polypodium trifoliatum. *Three-leaved Polypody.*
Lin. spec. 1547. *Reich.* 4. 415. *hort. cliff.* 475. *Pet. fil.* 18. *t.* 7. *f.* 3. *Brown. jam.* 97. 7. *Raii suppl.* 66. 2. (Lonchitis.) *Plum. amer.* 22. *t.* 32. *fil.* 127. *t.* 148. (Hemionitis.) *Sloan. jam.* 1. 85. *t.* 42. (Hemionitidi affinis.) *Pluk. phyt. t.* 291. *f.* 3. (Filix f. Hemionitis.)

Fronds ternate sinuate-lobed, the middle one larger.

4. *Frond pinnate.*

45. Polypodium Lonchitis. *Rough Polypody* or *Spleenwort.*
Lin. spec. 1548. *syst.* 936. *Reich.* 4. 415. *hort. cliff.* 475. *Hudf. angl.* 455. *Wither. arr. ed.* 3. 773. *Lightf. scot.* 668. *Fl. dan. t.* 497. *Act. nidrof.* 4. *t.* 5. *f.* 2, 3. *Gunn. norv. n.* 49. *Hall. helv. n.* 1711. *Scop. carn. n.* 1267. *Villars dauph.* 3. 840. *Gron. virg.* 123. *Bolt. fil.* 19.
Lonchitis aspera. *Baub. pin.* 359. *Raii hist.* 138.—ruajor. *Camer. epit.* 664. *Matth.* 922. *Baub. hist.* 3. 744. *Ger.* 979. *emac.* 1140. 3. *Park. theat.* 1042. 1. *Raii syn.* 118. *Mor. hist.* 3. 566. *f.* 14. *t.* 2. *f.* 1. *Pluk. phyt. t.* 89. *f.* 6.
β. Lonchitis mas f. latifolia aspera minor. *Barrel. ic.* 1121.

Fronds pinnate, pinnas crescent-shaped ciliate-ferrate declined, stipes strigose.

46. Polypodium muricatum. *Thorny-leaved Polypody.*
Swartz prodr. 131. *Sloan. jam.* 1. 81. *t.* 36. (Trichomanes.)

Fronds pinnate, pinnas falcate-lanceolate subferrate eared upwards, at bottom and in front spiny, stipe scaly.

47. Polypodium semicordatum. *Half-heart-leaved Polypody.*
Swartz prodr. 132. *Plum. fil. t.* 113. (Lingua cervina.)

Frond pinnate, pinnas parallel lanceolate very smooth, obliquely cordate at the base, the lower lobe more gibbous, fructifications in four rows.

48. Polypodium sagittatum. *Arrow-leaved Polypody.*
Swartz prodr. 132.

Frond pinnate, pinnas lanceolate blunt entire, having a toothlet on each side at the base, the lower one mutilated triangular minute.

49. Polypodium exaltatum. *Lofty Polypody.*
Lin. spec. 1548. *Reich.* 4. 416. *Brown. jam.* 99. 14. *Plum. amer.* 19. *t.* 28. *Sloan. jam.* 1. 77. *t.* 31. (Lonchitis.)

Fronds pinnate, pinnas ensiform entire, gibbous at the lower base inwards, at the upper base upwards.

50. Polypodium rhizophyllum. *Rooting-leaved Polypody.*
Swartz prodr. 132.

Fronds pinnate decumbent, tailed at the tip, the fruiting ones rooting, pinnas ovate-deltoid.

51. Polypodium auriculatum. *Eared Polypody.*
Lin. spec. 1548. *Reich.* 4. 416. *fl. zeyl. n.* 383. *Brevn. cent.* 189. *t.* 44. *f.* 2. *Raii suppl.* 69. 2. *Burm. zeyl.* 98. *t.* 44. *f.* 2. *Pluk. phyt. t.* 30. *f.* 4. (Filix.) *Mor. hist.* 3. 566. (Lonchitis.)

Fronds pinnate, pinnas falcate-lanceolate ferrate, truncate at the base, eared upwards.

52. Polypodium unitum.
Lin. spec. 1548. *syst.* 936. *Reich.* 4. 416. *Desfont. atlant.* 407. *Pet. mus.* 10. *t.* 1. *f.* 55. *Burm. zeyl.* 98. *t.* 44. *f.* 1. (Filix.)

Fronds pinnate, pinnas ensiform serrate, serratures semiovate ovate-nerved.

53. Polypodium sophoroides.
Thunb. in Linn. transf. 2. 341.

Fronds pinnate, pinnas ensiform gash-serrate, serratures semiovate nerved, the lowest serrature longer above.

54. Polypodium triangulare. *Triangular-leaved Polypody.*
Lin. spec. 1549. *Reich.* 4. 417. *Pet. fil.* 76. *t.* 1. *f.* 10. *Plum. fil.* 54. *t.* 72.

Frond pinnate, pinnas triangular toothed.

55. Polypodium obliteratum.
Swartz prodr. 132.

Frond pinnate, pinnas alternate broad-lanceolate attenuated crenate, notches at the tip and base obliterated on both sides.

56. Polypodium crenatum. *Notch-leaved Polypody.*
Swartz prodr. 132. *Plum. fil. t.* 3. *amer.* 10.

Frond pinnate, pinnas oblong-lanceolate crenate-smooth, fructifications in double rows.

57. Polypodium cordifolium. *Heart-leaved Polypody.*
Lin. spec. 1549. *Reich.* 4. 417. *Plum. fil.* 54. *t.* 72. *Pet. fil.* 75. *t.* 1. *f.* 11. (Trichomanes.)

Fronds pinnate, pinnas cordate blunt quite entire repand.

58. Polypodium simile.
Lin. spec. 1549. *Reich.* 4. 417. *Laur. cochinch.* 674. *Sloan. jam.* 1. 77. *t.* 32. (Lonchitis.)

Fronds pinnate, pinnas lanceolate quite entire distant, the upper ones smaller, dots in rows.

59. Polypodium dissimile.
Lin. spec. 1549. *Reich.* 4. 417. *Brown. jam.* 100. *n.* 23. *Pluk. phyt. t.* 288. *f.* 1. (Filix.)

Fronds pinnate, pinnas lanceolate subpubescent confluent, the lower ones distinct, dots scattered.

60. Polypodium Serra. *Saw-leaved Polypody.*
Swartz prodr. 132. *Sloan. jam.* 1. 90. *t.* 48. *Pluk. phyt. t.* 244. *f.* 1.

Frond bipinnatifid, pinnas linear very long attenuated ferrate, serratures semiovate acute striated.

61. Polypodium tetragonum. *Square-stalked Polypody.*
Swartz prodr. 132.

Fronds bipinnatifid, pinnas lanceolate acuminate opposite distant horizontal, segments ovate bluntish, stipe four-cornered.

62. Polypodium sanctum.
Swartz. prodr. 133.
Acrostichum sanctum. *Lin. spec.* 1526. *Brown. jam.* 105. *n.* 5. *Diff. noftr.*

Fronds subbipinnate, upper pinnas ecaudate, lower linear blunt entire, lowest biggish acute crenate.

63. Polypodium reticulatum. *Netted-leaved Polypody.*
Lin. spec. 1549. *Reich.* 4. 417. *Plum. amer.* 6. *t.* 9. *fil. t.* 92.

Fronds pinnate, pinnas oblong quite entire anastomosing rectangular, dots rectangular approximating.

64. Polypodium deltoideum. *Deltoid Polypody.*
Swartz prodr. 133.

Frond bipinnatifid, lower pinnas abbreviated entire oblong deltoid reflex.

65. Polypodium cicutarium.
Lin. spec. 1549. *Reich.* 4. 418. *Brown. jam.* 97. *n.* 8.

Fronds ternate, leaflets bipinnate laciniate at the base bluntly gash-ferrate acuminate, the lowest more gibbous.

66. Polypodium

66. Polypodium fontanum. *Rock Polypody.*
Lin. ſpec. 1550. *ſyſt.* 937. *Reich.* 4. 418. *Gouan illuſtr.* 80. *Hudſ. angl.* 456. *Wither. arr. ed.* 3. 777. *Hall. helv. n.* 1706. *Laws herborn. n.* 790. *Pallas it.* 2. 28. *Villars dauph.* 3. 849. *Allion. pedem. n.* 2413. *Bolt. fil.* 21.
Adianthum album. *Lob. adv.* 361. 2. *ic.* 810. 1. *Ger.* 980. 2. *Barrel. ic.* 452. *f.* 1.
Filicula ſaxatilis omnium minima elegantiſſima. *Tournef. inſt.* 71. *Pluk. phyt. t.* 89. *f.* 2. 3. *Garid. aix.* 183. *Raii exter.* 126 & 296.
F. fontana. *Tabern. ic.* 792.—minor. *Bauh. pin.* 358.
Fronds pinnate lanceolate, leaflets roundiſh ſharply gaſhed, ſtipe even.
67. Polypodium falcatum. *Sickle-leaved Polypody.*
Lin. ſyſt. 937. *ſuppl.* 446. *Thunb. jap.* 336. *t.* 36.
Fronds pinnate, pinnas cordate falcate acuminate entire, fructifications approximating ſcattered.
68. Polypodium marginale.
Lin. ſyſt. 937. *Thunb. jap.* 337.
Fronds pinnate, upper pinnas coaleſcent, lower enſiform eared upwards gaſhed, ſtipe villoſe.
69. Polypodium evectum.
Forſt. prodr. n. 438.
Fronds pinnate, pinnas oppoſite oblong, at the top linear-acuminate ſerrate, fructifications in a continued line along the margin.
70. Polypodium hirſutulum.
Forſt. prodr. n. 439.
Fronds pinnate, pinnas oblong bluntly ſerrate, eared upwards at the baſe.
71. Polypodium tenellum.
Forſt. prodr. n. 440.
Fronds pinnate, leaflets alternate remote linear acuminate waved.
72. Polypodium diſſectum.
Forſt. prodr. n. 441.
Fronds pinnate, leaflets pinnatifid, pinnules oblong bluntly ſerrate, the lower ones longer ſcarcely coaleſcent.
73. Polypodium nymphale.
Forſt. prodr. n. 442.
Fronds pinnate pubeſcent, leaflets linear very long pointed ſerrate, pinnatifid at the baſe, ſegments oblong blunt ſcarcely falcated forwards.
74. Polypodium inviſum.
Forſt. prodr. n. 443. *Swartz prodr.* 133. *Sloan. jam.* 1. 90. *t.* 51. (Filix.)
Fronds pinnate ſmooth, leaflets linear very long pointed ſerrate-pinnate, pinnas lanceolate falcate-acute, connate at the baſe.
75. Polypodium pennigerum.
Forſt. prodr. n. 444.
Fronds pinnate ſmooth, leaflets linear very long pointed ſubpinnate, pinnas ovate-oblong blunt connate.

5. *Frond bipinnate* or *ſubbipinnate.*

76. Polypodium Phegopteris. *Wood Polypody.*
Lin. ſpec. 1550. *Reich.* 4. 418. *hort. cliff.* 475. *Fl. ſuec. n.* 945. *lapp. n.* 382. *Weiſ. crypt.* 306. *Hudſ. angl.* 456. *Wither. arr. ed.* 3. 775. *Lightf. ſcot.* 669. *Gunn. norv. n.* 50. *Hall. helv. n.* 1698. *Pollich pal. n.* 962. *Villars dauph.* 3. 850. *Bolton, fil.* 20. *Amm. aſt. petr.* 10. *t.* 21. (Phyllitis.) *Petit. epiſt.* 56. *t.* 50. (Filix.)
Filix minor britannica, pediculo pallidiore, alis inferioribus deorſum ſpectantibus. *Mor. hiſt.* 3. 575. *ſ.* 14. *t.* 4. *n.* 17. *f.* 3. *Raii ſyn.* 122.
Fronds ſubbipinnate, loweſt leaflets reflex, each pair united at the baſe by a four-cornered little appendage.
77. Polypodium retroflexum.
Lin. ſpec. 1550. *Reich.* 4. 419. *Plum. fil.* 52. *t.* 68. *Pet. fil.* 72. *t.* 1. *f.* 9. (Filicula.)
Fronds ſubbipinnate, loweſt leaflets reflex, pinnas jagged.
78. Polypodium fragrans. *Sweet Polypody.*
Lin. mant. 307. *Pallas, it.* 3. 293. *Deſont. atlant.* 408. *Lour. cochinch.* 675? *Amm. ruth.* 251. (Dryopteris.)
Fronds bipinnate, pinnas ovate ſublobed blunt naked underneath bent back at the edge, fructifications marginal.

79. Polypodium paraſiticum. *Paraſitical Polypody.*
Lin. ſpec. 1551. *Reich.* 4. 419.
Kari-welli-panna. *Rheed. mal.* 12. *p.* 35. *t.* 17.
Fronds ſemibipinnate lanceolate, lobules rounded quite entire ſtriated.
80. Polypodium varium.
Lin. ſpec. 1551. *Reich.* 4. 420. *Lour. cochinch.* 675.
Fronds lateral bipinnate, loweſt leaflet pinnatifid.
81. Polypodium criſtatum. *Creſted Polypody.*
Lin. ſpec. 1551. *Reich.* 4. 420. *Weig. obſ.* 35. *n.* 24. *Schreb. ſpicil.* 71. *Weis, crypt.* 317. *t. Hudſ. angl.* 457. *Wither. arr. ed.* 3. 778. *Lightf. ſcot.* 670. *Relh. cant. n.* 764. *Sibth. oxon. n.* 746. *Abbot, bedf.* 226. *n.* 736. *Hall. helv. n.* 1075. *Scop. carn. n.* 1271. *Mull. fridr.* 193. *n.* 845. *t.* 2. *f.* 4. *Bolton, fil.* 23.
Filix mas ramoſa pinnulis dentatis. *Ger. emac.* 1129. *Raii hiſt.* 150. *ſyn.* 124. *Pluk. phyt. t.* 181. *f.* 2.
Fronds ſubbipinnate, leaflets ovate-oblong, pinnas blunt ſharply ſerrate at the tip.
82. Polypodium patens. *Pubeſcent Polypody.*
Swartz prodr. 133. *Ait. kew.* 3. 464. *Sloan. jam.* 1. 91. *t.* 52. *f.* 1. (Filix.)
Frond bipinnatifid ſomewhat villoſe underneath, pinnas linear-lanceolate elongated, pinnules oblong acute entire, the loweſt longer.
83. Polypodium Filix mas. *Male Polypody* or *Fern.*
Lin. ſpec. 1551. *ſyſt.* 937. *Reich.* 4. 421. *hort. cliff.* 475. *fl. ſuec. n.* 946. *lapp. n.* 385. *mat. med.* 226. *Woodv. med. bot.* 136. *t.* 49. *Hudſ. angl.* 458. *Wither. arr. ed.* 3. 775. *Lightf. ſcot.* 671. *Relh. cant. n.* 765. *Sibth. oxon. n.* 748. *Abbot, bedf.* 226. *n.* 737. *Gunn. norv. n.* 4. *t.* 1. *f.* 4. *Hall. helv. n.* 1701. *Scop. carn. n.* 1270. *Pollich pal. n.* 963. *Villars dauph.* 3. 842. *Allion. pedem. n.* 2404. *D'Alſo arag. n.* 1000. *Deſont. atlant.* 405. *Weiſ. crypt.* 310. *Blackw. t.* 323. *Knipb. cent.* 6. *n.* 71. *Regn. bot. Bulliard herb. t.* 183. *Bolton, fil.* 44. *t.* 24.
Filix mas. *Fuchſ. hiſt.* 595. *Tabern. ic.* 591. *Matth.* 1290. *Dalech.* 1222. *Trag.* 546. *Dod. pempt.* 462. 1. *Camer. epit.* 991. *Lob. ic.* 812. *Ger.* 969. 1.
F. mas vulgaris. *Park. theat.* 1036. *Raii hiſt.* 143. *ſyn.* 120.
F. non ramoſa dentata. *Bauh. pin.* 358. *Tourn. inſt.* 536. *t.* 310—312. *Mor. hiſt. ſ.* 14. *t.* 3. *f.* 6.
F. vulgo mas dicta, ſ. non ramoſa. *Bauh. hiſt.* 3. 738.
F. mas non ram. pinnulis latis denſis minutim dentatis. *Ger. emac.* 1129. *t.* 1128. *f.* 1.
Fronds bipinnate, pinnas obtuſe crenulate, ſtipe chaffy.
84. Polypodium Filix fœmina. *Female Polypody* or *Fern.*
Lin. ſpec. 1551. *ſyſt.* 937. *Reich.* 4. 421. *fl. lapp. n.* 386. *ſuec. n.* 947. *Hudſ. angl.* 458. *Wither. arr. ed.* 3. 778. *Lightf. ſcot.* 673. *Relh. cant. n.* 766. *Sibth. oxon. n.* 749. *Abbot, bedf. n.* 738. *Gunn. norv. n.* 29. *Hall. helv. n.* 1704. *Pollich pal. n.* 964. *Scop. carn. n.* 1268. *Villars dauph.* 3. 845. *Weiſ. crypt.* 315. *β. Fronds bipinnate, pinnas lanceolate ciliate-toothed, ſtipe ſtrigoſe.

88. Polypodium hirtum.
Swartz prodr. 133.

Frond at bottom tripinnatifid, towards the top bipinnatifid and finally pinnatifid, ſegments ovate blunt almoſt entire, ſtipe and branches rough-haired.

89. Polypodium rhœticum. *Stone Polypody.*
Lin. ſpec. 1552. *Reich.* 4. 422. *Huds. angl.* 458. *Wither. arr. ed.* 3. 780. *Hall. helv. n.* 1708. *Pallas, it.* 2. 28. *Scop. carn. n.* 1272. *Gouan. monſp.* 528. *Villars dauph.* 3. 846. (polymorphum A.) *Bolt. fil.* 45. & 2. 6.

Filix montana ramoſa minor argute denticulata. *Raii ſyn.* 124. *Pluk. phyt. t.* 89 *f.* 4.

F. rhœtica tenuiſſima denticulata. *Bauh. hiſt.* 3. 740.

Filicula fontana major, ſ. Adiantum album, filicis folio. *Bauh. pin.* 358. *Mor. hiſt. ſ.* 14. *t.* 4. *f.* 8.

Fronds bipinnate, leaflets and pinnas remote lanceolate, ſerratures acuminate.

90. Polypodium elongatum. *Cut-leaved Polypody.*
Ait. kew. 3. 465.

Fronds bipinnate ſmooth, pinnas blunt ſharply ſerrate, the upper ones ovate, the middle oblong, the lower lanceolate pinnatifid ſharpiſh.

91. Polypodium noveboracenſe.
Lin. ſpec. 1552. *Reich.* 4. 423.

Fronds bipinnate, pinnas oblong quite entire parallel, ſtipe even.

92. Polypodium pubeſcens.
Lin. ſpec. 1552. *Reich.* 4. 423. *Brown. jam.* 101. *n.* 25.

Fronds bipinnate hairy, pinnas lanceolate-ovate ſomewhat gaſhed acute, the outmoſt confluent.

93. Polypodium marginale. *Marginal flowering Polypody.*
Lin. ſpec. 1552. *Reich.* 4. 423.

Fronds bipinnate, pinnas ſinuate repand at the baſe, fructifications marginal.

94. Polypodium bulbiferum. *Bulbiferous Polypody.*
Lin. ſpec. 1553. *Reich.* 4. 423.

Filix baccifera. *Corn. canad.* 5. *Mor. hiſt.* 3. 579. *ſ.* 14. *t.* 3. *f.* 10.

Fronds bipinnate, leaflets remote, pinnas oblong obtuſe ſerrate bulbiferous underneath.

Lin. ſpec. 1555. *Reich.* 4. 427. *Pet. fil.* 53. *t.* 1. *f.* 6. *Plum. fil.* 29. *t.* 19. (Filix.)
Fronds bipinnate, pinnas ovate toothlet-ſpiny.

109. Polypodium villoſum.
Lin. ſpec. 1555. *Reich.* 4. 427. *Pet. fil.* 52. *t.* 4. *f.* 10. *Plum. amer.* 15. *t.* 23. *fil.* 21. *t.* 27. *Raii ſuppl.* 97. 2. *Sloan. jam.* 1. 100. *n.* 98. (Filix.)
Fronds bipinnate birſute, pinnas oblong obtuſe, the terminating ones acuminate.

110. Polypodium decuſſatum.
Lin. ſpec. 1555. *Reich.* 4. 427. *Pet. fil.* 61, 62. *t.* 2. *f.* 5, 6. *Plum. fil.* 19. *t.* 24. 20. *t.* 25.
Fronds bipinnate, pinnas horizontal quite entire obtuſe, the terminating ones lanceolate.

7. *Fronds ſuperdecompound.*

111. Polypodium axillare. *Slender Polypody.*
Ait. kew. 3. 466.
Frond tripinnate ſmooth, pinnas oblong, ſerrate at the tip, adnate, few-flowered.

112. Polypodium umbroſum. *Madeira Wood Polypody.*
Ait. kew. 3. 466.
Frond tripinnate ſmooth, pinnas lanceolate-linear ſerrate adnate many-flowered.

113. Polypodium Dryopteris. *Branched Polypody.*
Lin. ſpec. 1555. *ſyſt.* 939. *Reich.* 4. 427. *fl. lapp. n.* 387. *ſuec. n.* 949. *Hudſ. angl.* 460. *Wilber. arr. ed.* 3. 780. *Lightf. ſcot.* 678. *Sibth. oxon. n.* 751. *Hall. helv. n.* 1699. *Pollich pal. n.* 966. *Pallas, it.* 2. 26. *Weiſ. crypt.* 324. *Scop. carn. n.* 1276. *Villars dauph.* 3. 850. *Knipb. cent.* 12. *Bolton, fil.* 28.

Thelypteris minor pinnulis dentatis. *Amm. ad. petrop.* 10. 301. *t.* 22. *f.* 2.
Fronds ſuperdecompound, leaflets torn bipinnate.

114. Polypodium ſpelunceæ.
Lin. ſpec. 1555. *Reich.* 4. 428. *fl. zeyl. n.* 384. *Forſk. deſcr.* 185. *Leur. cochinch.* 677. *Burm. ind.* 234. *Pluk. phyt. t.* 244. *f.* 2. (Filix.)
Fronds ſuperdecompound hairy, leaflets lanceolate pinnate, pinnas oppoſite pinnatifid.

115. Polypodium capenſe. *Cape Polypody.*
Lin. ſyſt. 939. *ſuppl.* 445.
Cyathea capenſis. *Smith fil. dorſif.* 253.
Frond ſuperdecompound, leaves bipinnate, pinnas one-flowered at the baſe.

116. Polypodium æmulum. *Dwarf Madeira Polypody.*
Ait. kew. 3. 466.
Frond quadripinnatifid ſmooth, pinnas oblong-linear gaſhed, pinnules toothletted at the tip.

117. Polypodium denticulatum. *Toothletted Polypody.*
Swartz prodr. 134.
Frond quadripinnate at bottom, at top tripinnate ſmooth, pinnules wedge-ovate goſhed toothletted, fructifications ſolitary.

118. Polypodium armatum. *Armed Polypody.*
Swartz prodr. 134.
Fronds quadripinnate, pinnules lanceolate crenulate ſmooth above, birſute at bottom, fructifications crowded, branches and branchlets rough, trunk arboreous prickly.

119. Polypodium glaucum.
Swartz prodr. 134.
Fronds quadripinnate, branches and branchlets lanceolate, pinnas lanceolate pinnatifid, ſegments ovate acute glaucous underneath.

120. Polypodium diſſectum. *Cut Polypody.*
Swartz prodr. 134.
Lonchitis altiſſima globuligera minor. *Plum. fil. t.* 31.
Adianthum nigrum ramoſum max. *Sloan. jam.* 1. 96. *t.* 57. *f.* 1, 2.
Frond quadripinnatifid ſmoothiſh, pinnules ovate blunt gaſh-ſerrate, fructifications ſolitary, branches and branchlets pubeſcent.

121. Polypodium effuſum. *Spreading Polypody.*
Swartz prodr. 134. *Ait. kew.* 3. 467.
Adianthum nigrum ramoſum maximum follis ſ. pinnulis tenuibus longis acutis ſpinoſis. *Sloan. jam.* 1. 97. *t.* 57. *f.* 4.
Frond quinquepinnatifid ſmoothiſh membranaceous, pinnules acute finely ſerrate, rachis of the branches margined.

Species from Withering.

122. Polypodium ilvenſe.
Wither. arr. ed. 3. 774. *Dickſ. hort. ſicc.*
Acroſtichum ilvenſe. *Linn. & Dill. noſtr.*
Acr. alpinum. *Bolton, fil.* 42.
Fronds pinnate, leaflets oppoſite united blunt hairy underneath very entire at the baſe.

123. Polypodium arvonicum.
Wither. arr. ed. 3. 774. *Fl. dan. t.* 391. *Pluk. phyt. t.* 89. *f.* 5. (Filix.)
Acroſtichum ilvenſe. *Hudſ. angl.* 451.
Filix alpina pedicularis rubræ foliis ſubtus villoſis. *Llwyd in Raii ſyn.* 118.
Fronds pinnate, leaflets lanceolate pinnatifid hairy underneath, ſtipe hairy.

124. Polypodium dentatum.
Wither. arr. ed. 3. 776. *Dickſ. crypt. faſc.* 3. *t.* 7. *f.* 1, *hort. ſicc.*
Fronds pinnate, leaflets oppoſite pinnatifid, lobes ſparingly cut at the ſides, finely toothed at the ends, ſtipe very ſlender.

125. Polypodium ſpinuloſum.
Wither. arr. ed. 3. 778. *Fl. dan. t.* 707.
Fronds bipinnate, pinnas lanceolate, pinnules linear-ovate with ſharp-pointed teeth.

126. Polypodium trifidum.
Wither. arr. ed. 3. 779.
Cyathea incifa. *Engl. bot.* 163.
Fronds bipinnate, pinnas lanceolate blunt, pinnules of the lowermoſt pinnas moſtly trifid, ſtipe bordered.

Species from Forſter.

127. Polypodium veſtitum.
Forſt. prodr. n. 445.
Fronds ſubbipinnate, pinnas rhomb-ovate acute gaſh ſerrate, the loweſt lobed ſubpinnate, ſtipe covered with ſcariose ſcales.

128. Polypodium nudum.
Forſt. prodr. n. 446.
Fronds bipinnate, leaflets pinnate, pinnas rhombed goſh-crenate, ſtipe rugged naked.

129. Polypodium ſetoſum.
Forſt. prodr. n. 447.
Fronds bipinnate, leaflets ſubpinnate, pinnas linear gaſh-ſerrate, ſerratures ſetaceous, ſtipe villoſe.

130. Polypodium ariſtatum.
Forſt. prodr. n. 448.
Fronds bipinnate, lower leaflets pinnate, pinnas rhomb-oblong gaſhed, ſegments mucronate-ſerrate, ſtipe ſomewhat villoſe.

131. Polypodium adiantiforme.
Forſt. prodr. n. 4.9.
Fronds ſubbipinnate, leaflets ovate gaſhed, lobes ovate obtuſe crenate-ſerrate, the loweſt ſeparate, ſtipe ſcaleletted rough.

132. Polypodium medullare.
Forſt. prodr. n. 452. *eſcul.* 74. *n.* 48.

Fronds

Fronds bipinnate, leaflets pinnate very long-pointed, pinnas oblong subfalcate acute crenate, ſtipe rough, trunk arboreous biſpid.

133. Polypodium extenſum.
Forſt. prodr. n. 453.
Fronds bipinnate, leaflets pinnate acuminate ſerrate at the tip, pinnas oblong ſerrate, ſtipe rough with dots, ſtem arboreous.

134. Polypodium dealbatum.
Forſt. prodr. n. 454.
Fronds bipinnate, leaflets pinnate acuminate white underneath, pinnas oblong ſubfalcate ſerrate, ſtipe rough, trunk arboreous.

135. Polypodium affine.
Forſt. prodr. n. 455.
Fronds bipinnate, leaflets pinnate acuminate, pinnas linear-oblong crenate, ſtipe ſmooth.

136. Polypodium lunulatum.
Forſt. prodr. n. 456.
Fronds bipinnate, leaflets pinnate ſerrate at the tip ſetaceous, pinnas linear-oblong falcate ſerrulate at the tip, ſtipe rough.

137. Polypodium latifolium.
Forſt. prodr. n. 457.
Fronds ſubbipinnate, leaflets ovate acuminate pinnatifid and lobed, ſegments repand crenate, ſtipe very ſmooth ſhining.

DESCRIPTIONS, *&c.*

The inveſtigation of the ſpecies in this extenſive genus is attended with difficulties, from their general reſemblance in habit, the difference of their appearance at different ages, and the defect of their ſpecific characters. Nor have authors always been accurate in the terms uſed in deſcribing the fronds.

To remedy this in ſome degree, the plants ſhould not be gathered for examination, until they are in a ſtate of full fructification: and the attention ſhould be more particularly directed to the lower parts of the fronds, pinnas, &c. for there the characters are moſt conſtant and obſervable, the extreme parts generally running together ſo as to baffle every attempt at deſcription[x].

Add to this, that the far greater part of the ſpecies are of American growth, little known in Europe but from dried ſpecimens, not always collected with judgment enough to ſhow ſatisfactorily the true characters of the fronds and fructification. In Britain we have at moſt eighteen ſpecies; and very few more in all Europe.

We ſhould be ſcarcely juſtified, ſays Dr. Smith, in ſeparating *Polypodium vulgare* from the other ſpecies, becauſe it has no perceptible involucre. There might be more reaſon perhaps, conſidering the immenſity of the genus, for diſtinguiſhing thoſe in which the involucre is a part of a circle or reniform, from ſuch as have a perfectly umbilicated and circular involucre. But the limits are ſo difficult to define and deſcribe, that it ſeems much ſafeſt, until we get more information, to preſerve the genus as it is generally underſtood[y].

Dr. Smith, however, has removed ſeveral of the *Polypodiums* into his new genus *Cyathea*: and probably more of them will migrate into the ſame genus, when they are more accurately examined.

Linneus calls thoſe fructifications *ſolitary*, which are diſpoſed in one longitudinal row only on each ſide; *ſeriales* or in rows, which are digeſted tranſverſely, in a ſimple row, between each of the tranſverſe nerves; *ſcattered*, which are digeſted in two or more rows between the tranſverſe nerves.

1. Native of South America.

2. Stems many, very long ſlender and compreſſed, fixing themſelves to trees like Ivy, and putting out many branches, ſome very long, others ſhort, covered all over with little narrow acute ferruginous ſcales, interſperſed with abundance of ſmall filaments. Fronds alternate, four inches long, and ſeven or eight lines wide towards the lower part; they are gradually narrowed towards the tip, which is blunt, and the edges are waved; they are membranous, and the upper ſurface is ſmooth and of a bright green; the fructifications are hoary and in one row on each ſide of the midrib[a].

Native of the Weſt Indies, Jamaica, Martinico, Domingo.

3, 4, 5, 6. Natives of Jamaica.

7. Native of Hiſpaniola[b].

8. Native of the Society Iſlands[c].

9. Shoots ſlender, with ferruginous cloſe-preſſed hairs on them. Stipes ſcattered, two or three inches long, convex on one ſide, flattiſh on the other, hoary with villoſe cloſe-preſſed hairs not to be diſtinguiſhed without a magnifier. Fronds four inches long, attenuated at the baſe and acute, flat, hoary with minute ſtellate villoſe hairs underneath, but ſmooth above. Fructifications in a ſingle row along the edge, confluent, ferruginous, villoſe. It is the *P. ſerpens* of Forſter, but quite diſtinct from that of Swartz[d].—Native of New Zealand[e].

10. Root creeping, moſſy. Fronds rough with ſtiffiſh ſtrigæ. Fructifications bearded with fulvous wool[f].

Browne ſays, it creeps along the ground, and caſts its ſmall oval leaves on both ſides, in an alternate order; theſe ſeldom exceed an inch and quarter in length, and lie commonly cloſe upon the ground or rocks.

Native of South America: of Jamaica, according to Browne, but rare in that iſland.

11. Stipes ſeveral, aggregate, not more than an inch in length, flattiſh above, keeled underneath, ſmooth, even. Fronds three or four inches long, an inch wide, ſometimes widening in the middle to two inches, a little attenuated at the baſe, very blunt at the tip, thickiſh, ſcarcely veined. Fructifications large in proportion to the frond, diſpoſed longitudinally in a double row, and immerſed in the ſubſtance of the leaf. Found by Koenig in the Eaſt Indies[g].

12. Native of South America.

13. Native of South America. Swartz refers the firſt ſpecies of Browne to this: but he ſays the leaves are thin and delicate, which ill applies to the name of *craſſifolium*.

14. Root the thickneſs of a finger, five or ſix inches long, black on the outſide, having many fibres. Fronds ſix or ſeven, from two to three feet in length, acute at the end, narrow at the baſe, widening gradually, ſmooth, bright green on the upper ſurface; waved at the edge[h].

Native of South America, and the iſland of Jamaica, on the trunks of old trees, like our common Polypody.

15, 16. Natives of South America: and ſuſpected to be both very nearly allied to the preceding[i].

17. Root tomentoſe, fibroſe, not creeping. Fronds ſeveral, aggregate, erect, elliptic or attenuated at bottom and thence linear-lanceolate, acute very ſeldom biſid, entire with the margin rolled back, ſmooth, a ſpan long. Dots of the fructification in a ſingle row. —Native of Japan, flowering there in October[k].

18. Frond acuminate, erect, from a ſpan to a foot in length. Points of fructification ſcattered, ſolitary, next the midrib at the tip, two or more between the nerves in the middle, orbicular[l].—Native of Japan.

19. Stipe very ſmooth, black. The frond reſembles a flying bird and is three-lobed: lobes elongated, quite entire; the middle one twice as long as thoſe on the ſides, eared on both ſides at the baſe; the lateral ones have only one ear at the baſe. The fructifications are in ſcattered dots. Found in the iſland of Madaſcar by Sonnerat[m].

20. Frond ſimple trifid or quinquefid; the lobes lanceolate, quite entire, the middle one larger. The dots of fructification are rather large, ſcattered, remote. The upper ſurface above the dots gibbous and elevated[n].

According to Loureiro, the root is horizontal, fibroſe and creeping. Fronds half a foot long, ſimple,

[a] Plumier. [b] Swartz. [c] Forſter. [d] Vahl.
[e] Forſter. [f] Linn. ſpec. [g] Vahl. [h] Plumier.
[i] Linn. ſpec. [k] Thunb. jap. [l] Thunb. in Linn. tranſ.
[m] Linn. ſuppl. [n] Linn. mant.

[x] Withering. [y] Eſſay, 231.

petioled,

petioled, three-cleft or five-cleft; the segments quite entire, enſiform, acute or obtuſe. Fructifications ſcattered, remote: without any perceptible involucre, as in the common ſort, according to Dr. Smith.—Native of the Eaſt Indies and Cochinchina.

21. Native of Jamaica[a].

22. Root ſcaly with a brown villus on it. Stipe filiform, grooved, aſcending, ſmooth, a hand high. The lateral lobes of the frond ſmaller, the middle one twice the length of the two others, all lanceolate, acute, entire, ſmooth. Fructifications in a ſingle row on each ſide equidiſtant from the midrib. It differs from *P. trifurcatum* in having the baſe of the frond haſtate-trifid, and not three-forked at the tip.—Native of Japan; flowering from february to june[b].

23. Native of South America.

24. Native of Jamaica. This is the *P. ſcolopendroides* of Linnæus's firſt edition of his *Species Plantarum*, but not of his ſecond edition and *Syſtema Vegetabilium*. This therefore ought alſo to have been inſerted here under that name. The lower lobes in that are remote, whereas in this of Swartz they are united.

25, 26. Natives of Jamaica[c].

27, 28. Natives of South America. Suppoſed to be nearly allied[d].

29. Root creeps obliquely under the ſurface, ſending forth many fibres from little tubercles, it is about the thickneſs of the little finger or more ſlender, covered with brown moſſy ſcales, pale yellow on the outſide, greeniſh within. Stipes ſmooth, grooved on the inner ſide. Fronds from half a foot to a foot in length; the pinnas are ſlightly ſerrate at the edge, and paler underneath. Fructifications in two rows, one on each ſide of the midrib of the pinna or lobe, and parallel to it, in large yelloviſh brown round dots, pedicelled, of a roundiſh ſhape, with the ſurface granulated from the protuberance of the ſeeds, furniſhed with a ſhort elaſtic ſpring, and opening into two valves. Adanſon and Gleditſch, following Tournefort's figure, ſpeak of this fern as deſtitute of the ſpring, which ſeems common to all the ferns. Malpighi long ſince delineated it rudely, and Gleichen has ſince done it elegantly. The lower pinnas are frequently barren. In this ſpecies, the aſſemblages of capſules are not covered with an involucre, or if there be any, it ſoon falls off[e].

It is very common in woods and ſhady lanes on the old ſtumps of trees, and on rocks and walls: in fructification from june to october.

The root of Polypody was employed by the ancients as a purgative; and being thought uſeful in expelling bile and pituitous humours, was recommended in maniacal melancholical diſorders: but to act as a cathartic the root muſt be exhibited in its recent ſtate, and in a large doſe. As a demulcent or pectoral, its ſenſible qualities ſeem to promiſe more advantage: joined with liquorice its good effects have been experienced in coughs and aſthmatic affections. It is rarely uſed in this country[f].

Several varieties of Common Polypody are noticed. The ſmaller is ſcarcely deſerving of regard. Ray has one with the pinnas doubly ſerrate, found on the walls of Windſor Caſtle, and ſince by Dr. Stokes, in Worceſterſhire. Bolton has figured another (2. 5. *b.*) with the pinnas deeply ſcalloped. It was obſerved in a wood near Bingley in Yorkſhire, by Mr. Alexander. Dr. Withering has a third, which he names *acutum*; the pinnas being very long, diſtantly ſerrate, and tapering to an acute point. A ſpecimen of it was ſent him by J. W. Griffith, Eſq. from rocks in North Wales. But the moſt remarkable variety is that which has been long noticed under the name of Welſh Polypody, and is conſidered as a diſtinct ſpecies by Linnæus and others. In this the pinnas are pinnatifid, and the lobes ſerrate. It is certainly, ſays Mr. Lightfoot, no other than a variety of the common ſort, as I have had opportunities of determining, by obſerving its different gradations. In this ſtate it is analagous to a double flower among the more perfect plants, and therefore never produces fructifications. The ſame is obſervable in a variety of common Hart's tongue or *Aſplenium Scolopendrium*[g].

30. This very much reſembles the preceding, but is ſmaller and ſmooth underneath.—Native of Virginia and other parts of America.

31. Native of America[h].

32. Native of Jamaica, in low cool and ſhady places: it riſes in tufts, and ſeldom exceeds ten or twelve inches in length[i].

33, 34. Natives of the Society iſlands.

35. Native of Jamaica and Egypt.

36, 37, 38, 39, 40. Natives of South America[k].

41. Root or ſhoot creeping, wholly covered with brown tomentoſe radicles. Stipes angular, twiſted, ſmooth, erect, a ſpan high. Pinnas acuminate, ſmooth, remote, in four pairs with the end-lobe very large.—Native of Japan[l].

42. Root as thick as the thumb, and ſometimes a foot long, round, much branched, knobbed and fleſhy, green within, but without covered with very ſmall golden ſcales, with holes in the middle of the knots, occaſioned by fallen leaves. Fronds about a foot long, cut into ſeven or eight very deep ſegments, an inch wide, and three or four inches long, remote and acuminate; underneath is a double row of golden dots along the nerves of the ſegments[m].

Native of Jamaica and Martinico, on the trunks of large trees.—Cultivated here before 1742, by Robert James Lord Petre. It flowers in march[n].

43. Some of the leaves are entire, and wide, reſembling thoſe of the oak, others are laciniated, with the ſegments not reaching to the midrib, long, acute: the laciniate leaves are much longer than the others[o].

The fruiting frond is ſo like that of *P. aureum*, that it might be taken for the ſame; but the other leaves are ſhorter by half, wider, only ſinuated, like thoſe of the oak[p].—Native of the Eaſt Indies.

34. This fern riſes commonly to the height of twenty-four or thirty inches; its leaves are very large in proportion, and appear as if they had been torn at the margin[q]. The involucre is umbilicated, according to Dr. Smith.

Native of the Weſt Indies. Introduced in 1769, by Mr. George Houſtoun. It flowers here moſt part of the year[r].

45. Fronds in circles round the crown of the root, which is rough with the remains of decayed ſtipes, keeled from the pinnas being bent upwards on each ſide the leaf-ſtalks. Pinnas cloſely placed as to be imbricate, the lower edge covering the upper edge of the next beneath; ſerratures frequently but irregularly terminating in ſhort ſpine-like teeth, furrowed underneath with veins, the margin of the upper half of the baſe of each pinna parallel to the rachis or general ſtalk. Stipe furrowed above. Fructifications diſpoſed in two parallel lines on each pinna, with five or ſix dots forming two lines[s].

Dr. Withering obſerves, that the plant is about four inches long, and one inch broad, generally curved; and that the larger ſerratures of the pinnas end in ſemitranſparent thorns.

According to Lightfoot, the fronds vary from three to eight inches in length, and are ſtiff and rigid: the pinnas are ſupported on very ſhort but viſible foot-ſtalks, their upper edge ſlightly curved in a concave arch, the lower edge in a convex one, edged with ſerrated ſpinules. The pinnas are truncated at the baſe, their upper angle is elevated, but the lower one is as it were reſcinded, and deſtitute of ſpinules. The fructifications grow upon ten or twelve pairs of the uppermoſt pinnas, but the lowermoſt, which are about as many more, are barren. The ſcale or involucre, which covers each dot, is peltate. The capſules are globular, ſupported each on a foot-ſtalk, and containing each a ſingle ſeed, according to Gleditſch.

[a] Swartz. [b] Thunberg. [c] Swartz. [d] Linn. ſpec. [e] Curtis. [f] Woodville. [g] Fl. ſcot. p. 668 & 661. [h] Linn. ſpec. [i] Browne. [k] Linn. ſpec. [l] Thunberg. [m] Plumier. [n] Hort. kew. [o] Ray. [p] Linn. zeyl. [q] Browne. [r] Hort. kew. [s] Woodward in Withering.

Dr. Stokes remarks, that cultivation does not change the appearance of this fern.

Native of Britain, Norway, Switzerland, Dauphiné, Carniola, monte Baldo, and Virginia. The Virginian plant, according to Linneus, has the pinnas more elongated and leſs incurved, with the ſerratures leſs ciliate-ſpiny. In Wales, on the higheſt mountains of Caernarvonſhire and on Glydar near Llanberris: and in Scotland, at the foot of the rocks among the Highland mountains.

46. This has many long filaments and fibres for its roots, of a dark brown colour, having towards the top, where the root is round and ſolid, ferruginous hairs. Fronds from ſix inches to a foot and half in length: pinnas ſet alternately as thick as they can ſtand from the very root, each of an irregular figure like a trapezium, having very ſmall prickles at the corners, and a ſcarcely diſcernible midrib, on each ſide of which is a row of ſeeds in ſmall ferruginous ſpots.—Native of Jamaica[a].

47, 48. Natives of Jamaica[f].

49. This fern ſeldom riſes above two feet and a half or three feet in height; the ſtipe is very ſimple, and the pinnas pointed and entire; they are connected by very ſhort foot-ſtalks, and project backwards on each ſide of them[g]: they are about an inch in length, and half as broad. Fructifications in two rows of ferruginous ſpots, one on each ſide the midrib[h].

Native of Jamaica, and the continent of South America.

50. Native of Jamaica[i].

51. Native of the Eaſt Indies. Linneus informs us, that the whole plant, in his ſpecimen, is ſmooth[k]. According to Burman, the lower part of the ſtipe is very hirſute, being covered with ſpinules or ſmall ſcales, which diminiſh upwards, till it becomes quite ſmooth towards the top. Pinnas in the lower part commonly oppoſite, in the upper alternate, ſimple: the margin is ſcarce obſervably ſerrate, but each ſerrature is terminated by a very ſlender prickle or briſtle. Fructifications diſperſed in dots on the upper pinnas.

52. Stipe even, upright. Frond flat: pinnas lanceolate, acute, gradually decreaſing upwards, ſemipinnate. Lobes regular, ovate, ſubacute, crowded, ſlightly bowed on one ſide, decreaſing from the baſe of the pinnas towards the top, then confluent and becoming a narrow acute ſerrate appendix. Nerves tranſverſe, oblique, parallel. Fructifications in diſtinct approximating ſpots, in a ſingle row under the ſurface of each lobe, becoming rufous when ripe[l].

Native of the Eaſt Indies, and of Barbary near la Calle.

53. Frond a foot long or more, ſmooth: pinnas lanceolate, acute; ſerratures ovate, parallel-nerved, mucronate, frequently ſubfalcated by the revolute margins: the terminating pinna ſimple, gaſh-ſerrate. Fructifications near the margins of the inciſures. Thunberg at firſt took it for the *unitum*, which it very much reſembles, but it differs from that in having the pinnule or ſerrature at the baſe of the pinnas longer on the upper ſide. Native of Japan[m].

54. Native of South America[n].

55, 56. Natives of Jamaica[o].

57. Native of America[p].

58. Plant three feet high, upright, from an oblong thick horizontal ſimple root[q]. According to Sloane, five feet high. Stipe a foot and half long, roundiſh, dark brown or blackiſh. Pinnas about two inches long, and three quarters of an inch broad at the baſe, roundiſh and blunt at the end, not at all laciniated. On each ſide of the midrib many ferruginous round ſpots of fructifications.—Native of America and China.

59. Native of Jamaica, and other parts of the Weſt Indies.

60, 61. Natives of Jamaica[r].

62. Native of Jamaica. See *Acroſtichum ſaxatum*.

63. Native of America[s].

64. Native of Jamaica[t].

65. Theſe little plants riſe three or four together from a tufted fibrous root, and ſeldom exceed eight or ten inches in height: their foliage is divided very deep, and each lobe is again deeply crenated in the margin[u].—Native of Virginia and Jamaica.

66. This has the habit of *P. fragile*, but the leaflets are cloſer together, and not ſo deeply lobed. Fructifications in larger dots, proceeding not from a roundiſh ſcale, but from an oblong, linear, white valve or chink[x]. The plant is three or four inches high.

According to Gouan, it is eaſily known by its habit. The lower pinnas have the leaflets in threes or fours, ſubcuneiform palmate-toothed: but the middle ones conſiſt of five or ſeven longer acuter and narrower leaflets; finally the end ones are ſtill narrower and confluent.

Dr. Smith has removed this ſpecies into the genus of *Cyathea*. The frond is bipinnate and pinnatifid, its ſegments obovate and notched; the ſtalk winged; the flowers ſcattered; and the calyx torn[y].

Native of England, Germany, Switzerland, the South of France, Piedmont, Siberia, upon moiſt ſhady rocks. Above Hammerſham church, and near Wyburne in Weſtmoreland: alſo in Buckinghamſhire.

67. Stipe ſcaly eſpecially at the baſe, angular, ſtriated, cinereous, erect, a ſpan high: the ſcales are looſe and ferruginous. Pinnas alternate, petioled, wide at the baſe, very long pointed, ſomewhat waved about the edge; the upper ſurface deep green and even, the lower paler, netted, ſmooth; they are an inch or an inch and half in length; and the terminating pinna is three-parted[z].

It reſembles *P. lonchitis*, but the frond is larger, the leaflets on petioles though very ſhort ones, more pointed, and very bluntly ſerrate. The fructifications alſo are not in two rows, but ſcattered over the whole lower ſurface of the leaflets or pinnas, yet diſtinct[a].

Native of Japan, where it was found by Thunberg.

68. Stipes round, tomentoſe. Fronds pinnate below, pinnatifid above: pinnas enſiform, gradually ſhorter, gaſh-pinnatifid, eared upwards at the baſe: inciſures entire, with two fructifications on each ſide at the margin.—Native of Japan[b]. The involucre is nearly reniform[c].

69. Native of the Society Iſles.

70, 71, 72. Natives of the iſlands in the South Sea.

73, 74, 75. Natives of New Zealand[d].

76. Plant ſometimes nineteen, and ſtipe twelve inches high. The lowermoſt pair of leaflets not confluent, as all the reſt are, and placed an inch and half from the pair above it; in a vigorous plant bent almoſt back to back, in conſequence of which, when dried and gummed on paper, they form an acute angle with the ſtalk, and might lead ſuch as had not ſeen the plant growing, to ſuppoſe they were in the ſame plane with the reſt. Lobes ſemielliptical[e]. The whole plant is hairy[f]. The fructifications are diſpoſed in ſmall pale-brown dots, in two rows, near the edges of the pinnules[g].

Native of many parts of Europe and of Virginia, in the cleſts of rocks, moiſt and ſhady places and woods. With us in Devonſhire, Yorkſhire, Weſtmoreland, as Barrowfield wood near Kendal, and by the fall of Lodore near Derwent water; and in the lowlands of Scotland, as about Langholm and Pantonbridge, in Eſkdale, &c.

77. Native of America.

78. Stature of P. fragilis. When freſh-dried extremely fragrant. Stock dark purple, ſmooth and even, with pale red chaffs towards the baſe. Frond ſmooth and even. Pinnas oppoſite, ſeſſile, ovate, obtuſe, ſmooth on both ſides, pinnatifid; the margin thin, bent back, and at firſt covering the fructifications, as in *Pteris*. The fructifications, though marginal only, have the character of this genus, being

covered

covered with their proper ſcale or involucre, which is reniform; in other reſpects it approaches very near to Pteris [k].

Desfontaines deſcribes it as a dwarf plant, with fibroſe, brown, twiſted roots often pubeſcent; numerous, brown, filiform, erect, villoſe chaffy or naked ſtipes; frond ovate-oblong, flat; pinnules oppoſite, ſmall, linear ovate, decreaſing gradually, blunt, entire, lobed or even pinnate; the fructifications in a ſpherical granule are concealed under the folded margin of the pinnule as in *Pteris*, covered with pale membranes.

According to Loureiro, it is a foot high; the fronds radical, erect, ſubbipinnate, lanceolate, hairy; the leaflets crowded; the ſegments blunt, deeply ſerrate. Stipes chaffy, channelled, brown, ſcaly at bottom. Fructifications in rows. This can hardly be the ſame with the fern of Linneus's mantiſſa and Desfontaines.

Native of the South of France, and found by Koenig on the walls of Funſchal in the Eaſt Indies, according to Linneus in his mantiſſa. Desfontaines obſerved it in the fiſſures of rocks on mount Atlas: Loureiro, if his plant be the ſame, in Cochinchina.

The fern which Hudſon has under this name is ſuppoſed to be only a dwarf variety of *P. Thelypteris*; but Dr. Withering recommends farther attention to it from botaniſts who live near Keſwick, where Hudſon found it in moiſt cleſts of rocks.

79. Stipe even. Leaflets lanceolate, pinnatifid to the middle. Fructifications ſcattered.

Native of the Eaſt Indies, on trees [l]. Oſbeck found it in Java.

80. Stipe rough-haired. Frond pinnate, with the lateral leaflets pinnatifid at the baſe; all the pinnas ſeſſile, ſharply and very finely ſerrate; pinnules at the baſe turned downwards next the ſtipe, longer and ſemipinnatifid, by which mark this fern is very eaſily known. Thus the frond, which is ſimply pinnate at the tip, is bipinnate at the ſides, with the pinnule at the baſe elongated, pinnatifid. Found in China by Oſbeck [k].

81. This fern varies from ſix to eighteen inches or more in height; in a moiſt ſoil it is three or four feet high, and is tripinnate, on dry rocks and banks about a foot high, the firſt pair of pinnas the largeſt, the only pair triply divided. The ſtipe and nerves covered with brown filmy ſcales. Outline of the frond nearly triangular. The ſerratures end in ſhort awns. The terminating pinnas are confluent. Fructifications in numerous ſmall dots, in two rows, covered at firſt with a ſcaly involucre. Linneus ſays, that the lower pinnas are barren; but when the frond comes to maturity, the whole is generally fertile [l].

Native of the North of Europe, in moiſt woods and ſhady places in a gravelly ſoil; in chinks of moiſt rocks, on old walls, and in marſhy places at the foot of decaying oaks.

82. Not much more than a foot high, the twigs three inches long, and half an inch broad; the pinnules are a quarter of an inch long, and joined together almoſt to the end, with ferruginous dots on the back, and of a yelloviſh green colour on the upper ſide.

Native of Jamaica on the banks of Rio Cobre, below St. Jago de la Vega [m]. Introduced in 1784, by Mr. Lindſay [n].

83. Common Male Fern, as it is abſurdly called, is from a foot and half to four feet in height. The leaves grow in large circular tufts: they are firſt alternately pinnate, the pinnas increaſing in ſize from the baſe towards the middle, and afterwards gradually decreaſing upwards towards the ſummit of the leaf. Theſe pinnas are again pinnatifid, or ſubdivided almoſt to the nerve into linear obtuſe parallel lobes, crenate on the edges. The ſtipes are covered with brown filmy ſcales. Fructifications kidney-ſhaped, from three to eight on each lobe, in two rows near the baſe and diſtant from the edges; none at the end: they are covered with a permanent ſcaly ſhield or involucre, of a nearly reniform ſhape. Capſules a pale brown, ſurrounded with a ſaffron-coloured elaſtic ring [o].

Native of moſt parts of Europe, Barbary, &c. in woods, heaths, and ſtony places.

It ſeems to have the ſame qualities with the common Brake or *Pteris aquilina*. Both are burnt for their aſhes, which are ſold to the ſoap and glaſs-makers. The Biſhop of Drontheim relates, that the young curled leaves, at their firſt appearance, are boiled and eaten like Aſparagus; and that the poorer Norwegians cut off thoſe ſucculent laminæ, like the nails of the finger at the crown of the root, which are the baſes of the future ſtalks, and brew them into beer, adding a third part of malt: in times of great ſcarcity they mix it with their bread. He adds, that cut green and dried in the open air, it affords not only an excellent bitter, but infuſed in hot water, becomes no contemptible fodder to goats, ſheep, &c. which will readily eat, and ſometimes grow fat upon it [p].

The root of this Fern has lately been greatly celebrated for its effects upon the *Tænia* or Tape-worm. This vermifuge power of fern-root ſeems to have been known to Theophraſtus, Dioſcorides, Galen and Pliny; and was recommended by Hoffman and others among the moderns. Its uſe however was very generally neglected, till Madame Nouſer, a Surgeon's widow in Switzerland, employed a ſecret remedy as a ſpecific in the cure of the Tape-worm. The principal phyſicians at Paris having been deputed to make a complete trial of its efficacy, it was purchaſed by the King of France, and afterwards publiſhed by his order.

After the patient has been prepared by an emollient clyſter, and a ſupper of panada with butter and ſalt, he is directed to take in the morning, while in bed, a doſe of two or three drams of the powdered root (if an infant one dram.) The powder muſt be waſhed down with a draught of water, and two hours after a ſtrong cathartic, of calomel and ſcammony, is to be given, proportioned to the ſtrength of the patient. If this does not operate in due time, it is to be followed by a doſe of purging ſalts; and if the worm be not expelled in a few hours, the proceſs is to be repeated at proper intervals. For the ſucceſs of this, or a ſimilar mode of treatment in this country, ſee Dr. Simmons's account of the Tœnia: but whether the Fern-root or the ſtrong cathartic is the principal agent in the deſtruction of the worm, may admit of a queſtion; it appears however from ſome experiments made in Germany, that the Tœnia has in ſeveral inſtances been expelled by the repeated exhibition of the root, without the aſſiſtance of any purgative [q].

Dr. Withering informs us, that he has frequently uſed it, and ſeldom without the deſired effect. But he does not ſay whether he exhibited the fern-root, with or without cathartics.

84. Fronds a cubit high; the ſtalk generally waved and ſmooth, but ſometimes ſcaly. The firſt diviſion of the pinnas is diſtinct and diſtant, thirty or more in the ſeries; the nerves ſmooth, fine, and ſlender: the ſecond diviſion, or the pinnules upon theſe nerves, are alſo diſtinct, very fine, delicate and numerous, being upwards of thirty pairs upon each nerve, of a linear-lanceolate form and ſemipinnate, the lobes having generally two or three acute ſerratures at the extremity, often ending in a ſhort awn. Theſe lobes are tender and pellucid, commonly nine or ten pairs, varying much in figure, being ſometimes acute and falcated, which is their moſt uſual appearance, at other times truncated, and more deeply and acutely ſerrate [r].

The lower pair of leaflets on each pinna, that is the pair next to the principal or primary leaf-ſtalk, ſtands cloſe to it, and parallel with it, pointing upwards and downwards. The breadth of the leaflets varies conſiderably in different plants, but when they are narrow and the wings diſtant, the whole has a remarkably light and elegant appearance. There is one cluſter of capſules on each lobe of the leaflet, appearing at firſt in diſtinct round dots, each covered with a ſcale, which is deciduous. In a ripening

[k] Linn. mant. [l] Linn. ſpec. [m] Id. ib.
[n] Lightfoot, Withering. [o] Sloane. [p] Hort. kew.

[q] Lightfoot. [r] Idem. [s] Woodville. [t] Lightfoot.

ſtate

ſtate the whole of the leaflet ſeems covered by them; whilſt in *P. Filix mas* the upper end is always bare[s].

Dr. Smith remarks, that the involucre is creſcent-ſhaped, and ſeems inclined to refer this ſpecies to his genus *Darea*.

Native of the northern, and ſome of the more ſouthern parts of Europe, in moiſt and ſhady marſhy places, moiſt rocky woods, about rivulets and on heaths. By no means ſo common with us as the preceding.

85. Stem ſmooth with two furrows, ten or fifteen inches high. Pinnas alternate; ſegments linear-lanceolate, blunt, either entire or finely ſerrate: the two or three lower pairs of wings gradually ſhorter, and the loweſt pair often pointing downwards[t].

Some of the moſt remarkable particulars in which this ſpecies differs from *P. Thelypteris*, with which it has been confounded, as well as with *P. Filix mas*, are theſe. Firſt, *P. Thelypteris* has a ſmall creeping root. *P. Oreopteris* has a large ſcaly root, wrapped and tied together with ſmall ſtrong fibres which cannot be ſeparated without difficulty. Secondly, when *P. Thelypteris* grows old, the under ſide of the leaf is totally covered with the confluent fructifications, and the edges of the pinnules are reflexed or contracted. In *P. Oreopteris* the fructifications are always on the margins, both in a young and old ſtate, and never run into one another; the lobes are oval and plane. Thirdly, this plant is four times as large as *P. Thelypteris*, and the latter always grows in boggy places; whereas *P. Oreopteris* grows in dry woods, on moors and hills, very rarely near water[u].

Mr. Dickſon found it both in England and Scotland, moſt plentifully in the latter. Mr. Teaſdale, in woods at Caſtle Howard and Hornby. He mentions, that this fern has a very agreeable ſcent; and ſuggeſts, that perhaps *P. fragrans* of Hudſon may be a variety of it. Mr. Robſon, in moiſt woods near Darlington, never on dry hills in that neighbourhood. Miſs Read, in a wood at Old Foot's well near Bromſgrove. Dr. Sibthorp, on the north ſide of Shotover hill. According to Mr. Griffith, it is more frequent in mountainous ſituations than any other ſpecies.

86. This has the habit of *P. Filix mas*. The ſtipe is ſmooth; the barren leaves wider and more blunt. Old leaflets covered with capſules[x].

The pinnas are deeply divided, but the diviſions do not reach to the midrib: the lobes, when in ſeed are much contracted, and narrower than before the capſules are fully formed; but this is very general through the whole tribe[y].

Native of the northern parts of Europe in bogs. Near Bungay in Suffolk. In St. Faith's Newton bogs near Norwich. At the foot of Snowdon near Llanberris.

87. Leaves generally near a cubit high, of a firm and rigid texture. Stipe remarkably ſcaly, the baſe eſpecially is covered with numerous broad fuſcous membranes: the rib and nerves have a ſlight filmy down of the ſame colour. The primary pinnas are longeſt near the middle of the rib, and thence decreaſe gradually towards the top and baſe, from thirty to forty pairs in number. Theſe are again pinnated with about twenty pairs of irregularly oval, (or rhomboidal) acute, nerved, auriculated pinnules, (or having a projecting angle on the upper edge near the midrib) edged with ſharp prickly teeth. The firſt or loweſt of theſe pinnules, on the upper ſide, at the baſe of the nerve, is larger than any of the reſt. The extreme pinnules are confluent. The fructifications are as uſual in a double row, and are covered with peltate ſcales. Ten or more of the loweſt pairs are generally barren[z].

Native of moſt parts of Europe, of Barbary, Egypt, &c. in woods and ſhady places.

β. The young leaves put on a different appearance from the full grown ones. They vary from ſix inches to a foot in height, and are only ſimply pinnate; the pinnas of a lanceolate and falcate form, ſemipinnate, and edged with prickly ſerratures. The auricles at the baſe of the pinnas are conjoined at the top of the leaf, but often ſeparate at the bottom of it. In this ſtate, if there are any fructifications, they are only to be found upon ſix or eight of the uppermoſt pairs of pinnas. It grows in ſhady places[a].

88. Native of Jamaica[b].

89. Seven or eight inches high. Stipe red, ſmooth, ſlender, convex on one ſide, bare for two or three inches from the baſe. Pinnas acute. Leaflets linear-lanceolate. Mr. Bolton has well obſerved, that the pinnas are diſtinct all the way up, not becoming confluent at the top, and that the leaflets on the upper ſide the ſecondary midrib are larger than thoſe on the lower, by which it may be diſtinguiſhed from *P. fragile*. The regular ſerratures on the ſides of the lobes alſo afford a good diſtinction, the lobes in *P. fragile* being only ſerrate, towards the end, and that very irregularly[c].

Native of England, France, Germany, Switzerland, Carniola, Siberia. With us in Derbyſhire, Weſtmoreland, Wales and Scotland.

90. Native of Madeira and the Azores. Found there by Mr. Francis Maſſon. Introduced in 1779[d].

91. Habit and ſtructure of *P. Filix mas*, but the pinnas more approximating, quite entire, and having a great abundance of very ſmall floriferous dots; the ſtipe alſo is ſmooth and even. Found in Canada by Kalm[e].

92. This ſeldom riſes above eight or ten inches, and ſpreads into a branched foliage above the middle: theſe are ſimple, and furniſhed with oval alternate and jagged leaves: both the foliage and branches of the plant are adorned with a fine down.—Native of Jamaica, but not common there[f].

93. This has the habit of *P. Filix mas*, but the pinnas are oblong, not crenate, but bluntly ſerrate towards the baſe; it is plainly diſtinguiſhed by the pinnas having at each margin underneath two or three larger diſtinct dots, inſtead of many in the diſk, as in *Filix mas*[g].

According to Dr. Smith, the involucre is nearly reniform, as in that ſpecies.

Native of Canada; introduced in 1772, by Samuel Martin, M. D.[h]

94. Root of many capillary brown fibres. It is a ſlender plant, with narrow pinnules like thoſe of *P. Filix Fœmina*, but ſmaller, and of a yellowiſh green. Among the fructifications are round globules, firſt green, then black, of a ſweetiſh taſte, like the root of the common Polypody, which according to Cornutus when they are ripe fall to the ground, and ſtrike root; accordingly Linnæus calls them bulbs. Bobart rather conceives theſe globules, bulbs or tubers, to be the work of inſects, becauſe it is unuſual to find two ſorts of ſeeds on the ſame plant: but there are ſeveral plants which increaſe both by ſeeds and bulbs[i]. Native of Canada.

95. From four to ſeven inches high, or according to Lightfoot, from two to ten or twelve inches, but its moſt common ſtature about half a foot. Stipe red (at leaſt near the baſe, where it is bare for about two inches) ſmooth, ſlender, brittle. Pinnas nearly oppoſite, from ten to fifteen pairs, the lowermoſt very remote, ſhorter than the middle ones, all placed nearly at right angles with the rib. The pinnules in the ſecond diviſion ſix or eight pairs, each ſemipinnate, their lobes obtuſely oval, toothed on the edges, and about four or five pairs on each pinnule, with an odd one at the end. Leaflets more than twice as long as they are broad. Fructifications white at firſt, large for the ſize of the lobes, brown and confluent when ripe, covering the under ſide of the leaf, as in *Acroſtichum*.

Haller and Weis are of opinion, that *P. Rhæticum* of Linnæus is no other than a variety of this. In habit it approaches near to it, but it is not diſtinctly bipinnate like that plant, nor are the lobes of the leaflets regularly ſerrate at the edges, as in that[k].

According to Dr. Smith, who makes our *P. fragile* a *Cyathea*, the frond is bipinnate and pinnatifid, its ſegments obovate and notched, the ſtalk winged, the flowers ſcattered, and the calyx torn.

Native of Europe on rocks. In England, Peak's hole, and on walls about Buxton in Derbyſhire, near Hyde in Gloceſterſhire, in the road from Bourn Heath to Worms aſh near Bromſgrove. In Wales and in Scotland.

Dr. Withering has three varieties, but they have been all gathered from the ſame root. Villars unites the *fragile*, *regium*, *rhæticum*, and another which he names *laciniatum*, under the name of *polymorphum*.

96. Linneus remarks, that the globules of fructifications in this are larger than in the ſpecies allied to it.

According to Villars, it is about ſix inches high, the leaves are jagged in obtuſe ſegments, wider, rounded, little cut.

Scopoli deſcribes the ſtipes as a ſpan high, ſlender, red, ſmooth. Branches on each ſide to ſixteen; the firſt branches the length of the laſt joint of the thumb, and at the ſame diſtance; to theſe adhere alternate pinnules, to ſeven on each ſide, four or five lines in length, divided into oblong ſegments, three-cleft or four-cleft, ſimple, bluntiſh, a line long. At the origin of each ſegment is placed a yellowiſh globule of ſeeds.

Haller and Weis refer Vaillant's plant to *P. fragile*.

Native of France, Carniola and Piedmont.

97. This is a ſmooth, delicate plant, almoſt diaphanous. The barren leaves are much ſhorter than the fertile ones, and pinnate. Stipe capillary. Pinnules fan-ſhaped, gaſh-lobed; ſegments blunt, unequal. Fruiting leaves erect, on an even, brown, filiform ſtipe. Leaf bipinnate; leaflets often lobed-pinnatifid; lobes ſmall, obovate, blunt, ſometimes toothed at the tip, unequal. Granules very ſmall, aggregate ſcattered over the back of the frond [1].

Linneus, who doubted whether this fern is a *Polypodium*, ſays that it is a middle ſpecies between this genus, *Acroſtichum* and *Oſmunda*, Magnol and Barrelier make it an *Adiantum*, and Swartz affirms it to be a genuine *Aſplenium*; with bipinnate and tripinnatifid fronds, remote pinnas, cuneiform gaſhed lobes, and ſolitary fructifications.

Native of Spain, Portugal, Provence, and Barbary, near Algiers, in the fiſſures of rocks.

98. Root decumbent, thick, clothed with a very ſoft cloſe wool of a deep yellow colour. Stipes from a foot and half in height, green, even, obſcurely angular. Leaflets oblong, the loweſt oppoſite, the reſt alternate, with patulous axils: pinnas acute, with acute lobes ſerrate at the tip. The fronds are ſmooth [2].

Root oblong, horizontal, above a foot long, thick, roundiſh, fleſhy, many-formed, appearing above ground, to which it is faſtened by a few thick fibres: it is entirely covered with very cloſe, ſlender ruſous hairs. Fronds ſix feet high, radical, erect, few, unarmed: leaflets ſmooth, ſeſſile, oppoſite or alternate. Loureiro could not find any fructifications, though he ſearched diligently for them in the month of may, which probably was not the proper ſeaſon: Linneus's ſpecimens had no fructifications, we muſt yet therefore remain uncertain, whether this ſpecies be a *Polypodium*, though there is little doubt of it.

Many authors have writ upon the Barometz or Scythian Lamb, and moſt of them fabulouſly. Some, among whom is Kircher, have given a figure of it much reſembling a lamb, as the fruit of ſome plant on the top of the ſtalk. It is well known however to be the root, which from the variety of its form is eaſily made by art to take the form of a lamb, which the Tartars call *Borametz*, or rather that of a ruſous dog, which the common names in China and Cochinchina imply, namely *Cau-tieh* and *Keu-tſie*. The root riſes above the ground in an oblong form, covered all over with hairs; towards one end it frequently becomes narrower and then thicker, ſo as to give ſomewhat of the ſhape of a head and neck, and it has ſometimes two pendulous hairy excreſcences reſembling ears; at the other end a ſhort ſhoot extends out into a tail; four fronds are choſen in a ſuitable poſition, and are cut off to a proper length, to repreſent the legs, and thus a vegetable lamb or dog is produced, which at a due diſtance it may be eaſy to miſtake for a real animal. It is ſcarcely neceſſary to contradict the fables that have been related of this ſingular root of a fern; ſuch as that no graſs will grow near it, as if the Scythian Lamb had fed it bare. Loureiro, who had an opportunity of examining it in a living ſtate, in its native place of growth, affirms that the root when freſh cut yields a tenacious juice, very like the blood of animals in colour and ſubſtance, but that all the other wonderful ſtories that are told about it are fabulous. He ſays that the root is aſtringent, and will ſtop bleeding; and that it is of ſervice in the gonorrhœa and fluor albus [3].

In the account of the Tartarian Lamb in our Philoſophical Tranſactions, it is ſaid that the down of the root is commonly uſed for ſpitting of blood, about ſix grains going to a doſe, and three doſes pretended to cure ſuch a hæmorrhage: and that in China this down is uſed for ſtopping of blood in freſh wounds as cobwebs are with us; that they have it in ſo great eſteem there, that few houſes are without it. This down is of a dark yelloviſh ſnuff-colour, ſhining like ſilk, ſome of it a quarter of an inch long. The account ſays, that the root ſeemed to have been ſhaped by art, the climbing parts being made to reſemble the body, and the extant foot-ſtalks the legs; that it was more than a foot long, as big as one's wriſt, having ſeveral protuberances, and towards the end ſome ſtalks three or four inches long, exactly like foot-ſtalks of fern both within and without.

Bell, in his journey to Iſpahan, informs us that he walked many a weary mile accompanied by Tartars, in ſearch of this wonderful plant, but from his imperfect deſcription it does not appear that he ſaw the true plant.

Darwin thus characteriſes the Tartarian Lamb, adopting with poetic licence the fable related concerning it:

" Cradled in ſnow and fann'd by arctic air
" Shines, gentle Barometz! thy golden hair;
" Rooted in earth each cloven hoof deſcends,
" And round and round her flexile neck ſhe bends;
" Crops the grey coral moſs, and hoary thyme,
" Or laps with roſy tongue the melting rime;
" Eyes with mute tenderneſs her diſtant dam,
" Or ſeems to bleat, a *Vegetable Lamb* [4]."

Dr. de la Croix has alſo celebrated this Fern in the following Latin verſes.

" Surgit humo Boramez. Præcelſo in ſtipite fructus
" Stat quadrupes. Olli vellus. Duo cornua fronte
" Lanea, nec deſunt oculi, rudis accola credit
" Eſſe animal, dormire die, vigilare per umbram,
" Et circum exeſis paſci radicitus herbis:
" Carnibus ambroſiæ ſapor eſt, ſuccique rubentes,
" Poſthabeat quibus alma ſuum Burgundia nectar;
" Atque loco ſi ferre pedem Natura dediſſet,
" Balatu ſi poſſet opem implorare, voracis
" Ora lupi contra, credas in ſtirpe ſedere
" Agnum equitum, gregibuſque agnorum albeſcere colles."

The falſe figure in the Philoſophical Tranſactions will ſerve to explain in ſome meaſure the above lines.

Sir Richard Clayton has given this figure, together with thoſe of Dr. Hunter, and Dr. De La Croix, in the frontiſpiece to his elegant edition of the latter's *Connubia Florum*.

This ſingular fern is a native of Tartary, China and Cochinchina.

99. Root creeping, ſcaly; ſcales cloſe, membranaceous, brown, ſmooth. Stipe grooved, with remote torn ſcales, erect, two feet high. Fronds ſmooth: pinnas alternate: lower pinnules nearly diſtinct, upper united, loweſt ſubauriculate, very finely ſerrate, not ciliate, gradually ſhorter. Fructifications at the tip of the frond.—Native of Japan, flowering from may to november.

100. Stipe round, ruſeſcent, wholly covered with dark long looſe hairs. Loweſt pinnas bipinnate, upper

[1] Deſfontaines. [2] Linn. ſpec.

[3] Fl. cochinch. 675. 676.

[4] Loves of the plants, 2. p. 24. l. 249—256.

pinnate. Fructifications in the middle of the leaf in a ſingle row.—Native of Japan.

101. Stipe half round, ſmooth, a ſpan high and more, bifid at the top with the rudiment of a frond at the diviſion. Frond ſmooth: pinnas enſiform, pinnatifid; ſegments lanceolate, blunt, entire with a reflex margin. Fructifications in a ſingle row, at the margins of the ſegments, minute.—Native of Japan, flowering in june.

102. Shoot creeping, flexuoſe. Stipe round, ſmooth, flexuoſe-erect, commonly dichotomous, ſometimes but rarely trichotomous. Frond dichotomous-ſubpedate, bipinnate, ſmooth above, glaucous beneath. Pinnules united, acute. Fructifications ſmall in a ſingle row [r].

Native of Jamaica, Japan, and in the dry mountains of New Zealand and the Society Iſles.

The aſhes of this with powdered alum are exhibited in Aphthas and excoriations of the mouth in Japan [s].

The New Zealanders ſuck out the ſweetiſh farinaceous part of the root, having firſt roaſted it, and beat it well with a ſtone or club [t].

103. This fern riſes by a conſiderable hard ſimple and woody trunk to the height of twenty or twenty-five feet; it is, like the other ferns and palms, furniſhed only with ribs, which fall off gradually as it riſes, while the new ſhoots ſpring up from the top: it reſembles the Palm tribe alſo both in the form and ſtructure of its trunk, being very hard immediately under the bark, but looſe ſoft and fibrous in the middle. It holds for many years, bears all the inclemency of the weather with eaſe, and is frequently uſed for poſts, where the ſmaller palms are not at hand [u].

Loureiro ſays that the trunk is ſometimes armed with ſpinules: that the fronds are eight feet long, on roundiſh unarmed ſtipes: that the leaflets are lanceolate, ſerrate, ſmooth, bright green; and the fructifications in orbicular, rufous, ſcattered dots. In Cochinchina the trunk is uſed for rafters in building, and is accounted excellent for that purpoſe.

Dr. Smith removes it into his genus *Cyathea*, and deſcribes it as having an arboreſcent ſcaly trunk, a bipinnate frond, ſeſſile ſerrate pinnules with many flowers at their baſe, and an entire calyx.

Native of South America, Jamaica, Amboina, Cochinchina on the ſouth next Cambodia.

104. Trunk twenty feet high, as big as the human leg, undivided, covered with the ends of the fallen petioles, which are dark brown, as big as the finger, two or three inches long, thick ſet with ſhort and ſharp prickles. At the top of the trunk five or ſix fronds ſtand round, about ſix feet long, having a purple ſtipe, very thick ſet with ſhort ſharp prickles on its back. At about a foot from the trunk, each frond divides into oppoſite branches, placed near the bottom, at about ſix inches diſtance from each other. The branches are a foot long in the middle. The twigs come out alternately, being an inch and half long, and about two thirds of an inch broad, in the middle; they are made up of pinnules one third of an inch long, and half as broad, blunt, indented, dark green above, pale green below, very thin, and ſo cloſe ſet that there is no ſpace between them [x].

Native of South America and the Iſlands. According to Swartz it is a *Pteris*.

105. The lateral nerves of the fronds are branched again. The ſeminal dots are ſcattered near the margin [y].

Cyathea horrida of Smith; with the trunk thorny, the fronds bipinnate and pinnatifid, the ſegments acuminate, ſerrate at the tip, flowering near the margin, and furniſhed with interramifying veins at their baſe.—Native of the Weſt Indies.

106, 107, 108. Natives of America.

109. Stalks many, about two feet high, each as big as a finger, very hairy, and at about a foot from the ground divided into branches, the lowermoſt whereof are about nine inches long, almoſt oppoſite. Twigs more than an inch long, alternate, made up of broad, ſhort, moſtly entire, but ſometimes notched pinnules, roundiſh at the end, often united for ſome ſpace by their edges, pale green; covered, as well as the ſtalks branches and midribs with a whitiſh ſtrong ſhort hair [z].

Native of the Weſt Indies—Jamaica, Martinico, Dominica.

110. Native of the Eaſt Indies.

111, 112. Natives of the iſland of Madeira. Found there by Mr. Francis Maſſon. Introduced in 1779 [a].

113. Plant from five to eight inches or a foot high. Stipe ſlender, ſmooth, brittle, naked above half way up. The outline of the frond approaches near to an equilateral triangle. Pinnas about twelve or fifteen pairs, oppoſite; their ſubdiviſions nearly the ſame, ſmooth, of a pale green colour. Pinnules ſubdivided almoſt to the nerve; lobes linear, obtuſe; the lower ones crenate, the upper ones often entire, and running together. The pinnas do not grow exactly perpendicular, but decline towards the horizon. Fructifications in two rows of round dots upon each lobe; theſe, when ripe, cover the whole lower ſide of the leaf [b].

According to Scopoli, Tragus was the diſcoverer, Cluſius the illuſtrator of this ſpecies.

Native of many parts of Europe, on rocks and in dry ſtony places. With us chiefly in the northern counties, Scotland and Wales. Cornbury quarry in Oxfordſhire; in woods N. E. of the road up Froceſter hill, Gloceſterſhire; in Yorkſhire about North Bierly; among the rocks at the fall of Lodore on the ſide of Derwent-water, Cumberland. Barrowfield-wood near Kendal, and other rocky woods. In Scotland, at Langholm and Broomholm in Eſkdale, about Dunkeld, in Stormount, &c. In Wales, near Tintern-abbey in Monmouthſhire.

Bolton figures a variety with larger leaves: the largeſt lobes divided half way down to the midrib: the ſtalk taller, firmer, white, opaque. He found it in White-ſcars, near Ingleton, Yorkſhire, and in the Peak of Derbyſhire.

114. A foot and half high and unarmed. Fronds radical, ſuberect: pinnas deeply toothed [c].—Native of both Indies, Cochinchina and Egypt.

115. Leaflets lanceolate, alternately pinnate. Pinnas oblong, ſerrate, ſharpiſh, approximating at the baſe. Fructifications ſolitary at the baſe of the pinna [d].

Dr. Smith has removed it to his genus *Cyathea*, and deſcribes it as having a tripinnate frond; the leaflets ſeſſile, acute, ſerrate, bearing a ſolitary flower at their baſe; and the calyx torn. Gathered at the Cape of Good Hope by Dr. Sparrman.

116. Found in the iſland of Madeira by Maſſon. Introduced in 1779 [e].

117, 118, 119. Natives of Jamaica [f].

120. This riſes four or five feet high, having a ſmooth, reddiſh brown, ſhining ſtalk, the ſize of a finger, divided into alternate branches. Pinnules thick, blunt, variouſly ſinuated or deeply cut, eſpecially on their upper ſides, and indented about their round ends, of a dark green colour and ſhining on the upper ſide. Fructifications in ferruginous ſpots, eſpecially near the greater ſinuations by the edges.—Native of Jamaica [g].

121. This riſes three feet high, having a reddiſh ſmooth ſtalk, divided at one foot and a half from the ground into ſeveral branches, having their twigs, and they their pinnules, after the manner of *Adiantum nigrum*, only they are longer, thinner and ſharper at the point, having there a very little prickle, as well as others much ſmaller along their margin, where are no inciſures or very ſmall ones. It is ſometimes of a pale green colour, with almoſt pellucid thin leaves.—Native of Jamaica [h].

Introduced in 1769, by Mr. George Houſtoun [i].

122. Leaflets ſix or ſeven on each ſide the ſtem: the lower ones oppoſite, the upper alternate, thick and opaque, generally cloven into five or ſeven ſegments, rounded at the ends. See *Acroſtichum ilvenſe*.

[r] Thunberg. [s] Idem. [t] Forſter, eſcul. [u] Browne. [x] Sloane. [y] Linn. ſpec. [z] Sloane. [a] Hort. kew. [b] Lightfoot. [c] Loureiro. [d] Linn. ſuppl. [e] Hort. kew. [f] Swartz. [g] Sloane. [h] Hort. kew.

On Ben Lawers in Scotland, and Clogwyn y Garnedd in Wales.

123. From three to five inches high. Leaflets from seven to fifteen pairs, cloven on each side into five or six segments, spear-shaped, hairy underneath. It is a very rare plant even on Snowdon, where it was found by Mr. Lhwyd. Dr. Richardson also found it almost at the top of Clogwyn y Garnedd.

This seems sufficiently distinct from *P. ilvense* found on the Scottish alps by Mr. Dickson. Mr. Griffith thinks that Bolton's fern figured in t. 9. is only a very small and stiff plant of *P. fragile*, gathered in a high exposed situation, and that it is not the plant found by Lhwyd[g].

124. This nearly resembles *P. fragile* in size and habit. Root small, fibrous, bundled, a little woolly. Stipes several, slender, pale brown, shining, somewhat scaly at the base. Fronds bipinnate, lanceolate: leaflets remote, lanceolate, mostly alternate: pinnas ovate, obtuse, gashed, unequally toothed; teeth rather distant, obtuse, pale brown. Fructifications towards the edge, near the incisions[h].

Such is the account given by Mr. Dickson of this new species, which he first discovered in clefts of rocks in the highlands of Scotland; but though his description and specific character mention its being bipinnate, neither his own figure, nor the specimens in his fasciculi of dried plants, authorise us to say that they are so. They are only simply pinnate, and the pinnas divided into lobes, nor have they any proper midrib. *P. dentatum* of Forsk. in Gmel. syst. is a different plant[i].

125. This has been taken for *P. cristatum*, but it is very different from that: of a more delicate and transparent texture; the leaf-stalk but little if at all scaly, the opposite leaflets on the wings not unequal in size, and the midrib serpentine. It agrees with it in the disposition of the fructifications, and in the serratures ending in short awns.

Found on bogs on Birmingham heath; and Holloways in Devonshire[k].

126. Three or four inches high. Stem brown green, slender, bare for an inch or more at the base, edged with a narrow border on each side. Pinnas nearly triangular. Leaflets three-cleft, the middle segment sometimes notched[l].

The chief difference between this and *P. fragile*, which it much resembles in habit, consists in the divisions of the leaves being obtuse in this, and perfectly destitute of the bristly point observable in the other. There is also some difference in their habit and appearance, and the fructification of *P. fragile* is blacker. Dr. Smith has been inclined to believe it the *P. regium* of Linneus, but the original specimen of that in the Clifortian herbarium has a triangular, not lanceolate frond. Neither is ours *P. alpinum* of Jacquin, the divisions of which are linear, or nearly so.

Dr. Smith has removed this and *fragile*, into his genus *Cyathea*, in which the young captules are enveloped in a globular membrane, which goes underneath them, and bursts either at the top in an even and lacerated manner, or at the side, as in this species and some others[m].

In some specimens the fronds are broader and more dilated than in the figure given in English Botany.

Found by J. Wynne Griffith, Esq; of Garn near Denbigh, on Cwm Idwel; and by Mr. T. F. Forster, jun. on a wall near Walthamstow in Essex.

127 to 137. Natives of the islands in the great South Sea: 132 and 134, in New Zealand. N. 132. *P. medullare* is thus described by Forster. Trunk a fathom in height, spongy, full of pith, on the outside hispid and black from the fall of the stipes, crowned at the top with very large fronds spreading out almost horizontally. Frond a fathom and more in length; the stipe rough all over with small callous red tubercles or dots. Leaflets crowded, pinnate, the lower ones two inches long, narrow, very long pointed. All the pinnules sessile, oblong-crescent-shaped, acute; the lowest separate, crenate; the upper ones gradually shorter, connected, so that the apex of the leaf is plainly serrate, with deep sharp teeth. Fructifications globular, biggish, on the disk in a single row.

It is frequent in the woods of New Zealand, where it is called *Mamaga*. The inhabitants eat the pith of the root and lower part of the trunk roasted. It has a taste like that of the Turnep, but better, and approaches to the Sago. The pith abounds in a glutinous red juice, such as was noticed in *P. Barometz*[n].

Allioni and Villars have several species not noticed above:

1. Polypodium Pontederæ.
   Allion. pedem. n. 2405. *Hall. helv. n.* 1702.
   Filicula alpina fol. rotundioribus crenatis. *Ponted. compend.* 19. *Segnier suppl.* 54. *t.* 1. *f.* 2.
   Pinnas few, semipinnate very short acutely serrate.
2. Polypodium molle.
   Allion. pedem. n. 2406. *Villars dauph.* 3. 845. *Hall. helv. n.* 1703.
   Filix mollis f. glabra, vulgari non ramosæ accedens. *Bauh. hist.* 3. 738.
   Fronds subbipinnate, pinnas lanceolate bluntish, crenulate at the tip.
3. Polypodium alpinum.
   Allion. pedem. n. 2409. *Hall. helv. n.* 1709.
   Filicula alpina crispa. *Bauh. pin.* 358. *Segnier suppl.* 55. *t.* 1. *f.* 3.
   Fronds bipinnate, very loosely divided, lobes blunt toothed.
4. Polypodium montanum.
   Allion. pedem. n. 2410. *Hall. helv. n.* 1710.
   Cyathea montana. *Smith fil. dorsif.* 254.
   Filix rhœtica tenuissime divisa. *Bauh. hist.* 3. 740.
   Frond trifid bipinnate pinnatifid, segments slightly crescent-shaped toothed at the tip, rachis winged, fructifications scattered.
5. Polypodium pterioides.
   Villars dauph. 3. 841.
   Filix pyrenaica neque ramosa neque dentata. *Tournef. herb.*
   Fronds bipinnate, wings bowed upwards, leaflets blunt dotted underneath at the edge, with nine simple veins running along them above.
6. Polypodium carthusianum.
   Villars dauph. 3. 842.
   Fronds alternately bipinnate remote, leaflets acutely serrate, teeth often awned and bifid.
7. Polypodium aristatum.
   Villars dauph. 3. 844. *Hall. helv. n.* 1705.
   Fronds subtripinnate, pinnules serrate on both sides.
8. Polypodium myrrhidifolium.
   Villars dauph. 3. 851. *t.* 53.
   Fronds triangularly quadripinnate, leaflets gash-serrate confluent at the tip.

DESCRIPTIONS, &c.

1. Native of Switzerland and Italy.

2. Height from eight inches to a foot. Stem weak and thin. Leaves almost transparent, bipinnate with two or three divisions at the extremity of each leaflet. The dots of fructification are placed before the last division of the leaflets, and are round, not oblong, as in *P. Filix formina*, which this resembles. The plant is also thinner, less compounded, and only half the size[o].

3. Native of Switzerland and Italy. Jacquin has a fern with the same name[p].

4. Native of the European Alps. The calyx of this is torn. It belongs to the genus *Cyathea*, with several of the other species[q].

5. Height about two feet: it has only one sort of bipinnate leaves, with raised pinnas, the blunt leaflets of which have the fructifications very near the margin; and marked with nine pairs of simple nerves above.—Native of Dauphiné and Savoy but not common.

6. This is perhaps only a variety of *P. fragrans*, but it is less cut, higher, glaucous underneath, the leaves are alternate and less remote.—Native of Dauphiné.

[g] Withering. [h] Dickson. [i] Withering. [k] Idem. [l] Idem. [m] Engl. bot.

[n] Forst. fscul. [o] Villars. [p] Collect. 2. 172. [q] Smith, Essays.

7. This fern reſembles *P. Lanchitis* in the darkneſs of its green colour, and in the little ſpines at the end of the leaflets and ſerratures; but the leaf of this is triangular, wider, black at its baſe, and loaded with a great quantity of ſcales.—Native of Dauphiné and Switzerland.

8. This ſpecies has the moſt decompounded leaves of any; in the triangular outline and diviſions it reſembles much *P. Inſitanicum* of Linneus, but the extremities of the leaflets are much finer, and the plant thinner and lower. The fine cut of the leaves, like *Myrrhis odorata*, makes it eaſily known. Dauphiné, near the Grande Chartreuſe *.

Villars gives Allioni's *P. montanum* as a ſynonym, and n. 3. p. 124. of Ray's ſynopſis, which Hudſon refers to *P. rhæticum*.]

PROPAGATION AND CULTURE.

The common Polypody, and all the other ſorts which are hardy enough to bear the open air, being perennial plants may be propagated by parting their roots in the ſpring before they ſhoot, and ſhould be planted in a poor moiſt ſoil under the ſhade of a wall, for if they are expoſed to the ſun, they will not thrive. Many of them grow out of the joints of walls and old buildings, and the fiſſures of rocks, but are commonly found expoſed to the north. [They are well adapted therefore to ornament ruins and rock-work.

Nat. order of *Muſci* or *Moſſes.*

GENERIC CHARACTER.

Capſ. oblong, ſometimes quadrangular, placed on a quadrangular apophyſis. *Periſtome* double: *outer* with thirty-two ſhort teeth, united at the baſe, incurved; *inner* a flat membrane, tranſverſe, glued to the apexes of the teeth of the inner one. *Calyptre* hairy.—*Male* flowers diſcoid, or a circular bud, on a different plant, terminating.

ESSENTIAL CHARACTER.

Capſ. lidded, on a very ſmall apophyſis or receptacle. *Capſ.* villoſe.

SPECIES.

There are only five ſpecies of this Moſs in the fourteenth edition of Syſtema Vegetabilium. Dr. Withering in his third edition of the Arrangement of Britiſh Plants has ſix ſpecies, beſides ſeveral varieties. Dillenius, Hedwig and others, have figured them. Polytrichum commune. Great Golden Maidenhair or Goldilocks, is figured by Micheli, Gerarde, Parkinſon, &c. &c. It is found abundantly in woods and on moors in boggy places. When the Laplanders ſleep all night in the woods, they make themſelves beds of this Moſs; the bears collect it for the ſame purpoſe; ſquirrels and birds alſo uſe it in making their neſts*. Other ſpecies are figured by Vaillant, and in *Flora danica*. Mr. Curtis has detailed the characters very ſatisfactorily in his plate of *P. ſubrotundum*; and Hedwig, *ſtirp.* 1. 13, 14, 15.

Mr. Archibald Menzies has new-modelled this genus, diſtinguiſhed and deſcribed the ſpecies, and added ſeveral new ones. His eſſential character is this:

Capſ. operculate or lidded, roundiſh oblong or quadrangular.

Periſt. toothed: teeth incurved (thirty-two to ſixty-four) glued together at the tips by a tranſverſe membrane.

Calypt. or Veil double: inner ſmooth membranaceous ſmall; outer floccoſe with the tips united.

Male diſk-form, on a diſtinct plant.

Obſ. Linneus's character from the *apophyſis* is excluded, being found only in *P. commune*, and a few others.

Mr. Menzies has given nineteen ſpecies, ſeveral of them are inhabitants of North America, and ten are natives of Britain. The ingenious author has characterized and deſcribed them in the moſt ſatisfactory manner; and has figured eleven with the utmoſt accuracy. For the others he refers to the figures of Dillenius, Vaillant, Hedwig, &c.

The following extract from this very valuable monograph, is as much as is conſiſtent with the plant of this work, in the claſs Cryptogamia.

GENERIC CHARACTER.

* *Male* Flowers.

CAL. *Perianth* one-leafed, wheel-ſhaped, ſix-cleft, very ſhort: *ſegments* rounded.

COR. *Petals* ſix, orbicular, erect, a little longer than the calyx. *Nectary*, a raiſed rim, with ſix little ſwellings.

STAM. *Filaments* ſix, awl-ſhaped, erect, three times as long as the corolla, placed on the margin of the nectary. *Anthers* parabolical, biſid at the baſe.

PIST. *Rudiment* in the centre of the flowers.

* *Female* Flowers, in the ſame raceme with the Males.

CAL. and COR. as in the Males.

PIST. *Germ* obcordate, twin, two-celled. *Style* filiform, four times as long as the corolla. *Stigma* ſimple, compreſſed.

PER. *Berry* globular, fleſhy, ſuperior.

SEED ſingle, ovate, in the centre of the berry.

OBS. *Sometimes rudiments of ſtamens are obſerved in the female flowers. One cell of the germ is entirely obliterated in the ripe fruit.*

ESSENTIAL CHARACTER.

Cal. one-leafed, ſix-cleft. *Pet.* ſix.

MALE. Stamens ſix.

FEM. *Berry* globular, with one ſeed in the centre.

SPECIES.

1. Pometia pinnata.
Forſt. prodr. n. 392.
Palorum arbor alba latifolia. *Rumph. amb. 3. t. 65.*
Leaves pinnate, raceme ſuperdecompound terminating.
2. Pometia ternata.
Forſt. prodr. n. 393.
Leaves ternate, racemes almoſt ſimple axillary.

DESCRIPTIONS, *&c.*

1. Native of the iſlands of Tanna and Namoka, in the South Seas[1]. Juſſieu doubts whether it may not be of the ſame genus with Commerſon's Euphoria, which comprehends the celebrated fruits of the Chineſe, *Lit-chi* and *Lon-gan*[2].

2. The parts of fructification are not ſix, as in the preceding; but two, and multiples of that number. The calyx is four-leaved; the corolla four-petalled, with a four-cleft nectary; eight ſtamens; germs and ſtyles two, the former one-celled, valveleſs, incloſing one ſeed.—Native of New Caledonia[3].

Forſter named this *Aporetica*, ſignifying doubtful or ambiguous, the characters being ſo ſmall, that it is difficult to determine the genus. The flowers are male and hermaphrodite.

POMIFERA. See *Anacardium* and *Genipa.*

POMMEREULLIA. (*So named by the younger Linnæus, in memory of the very illuſtrious lady Du Gage de Pommereull who laboured at the inveſtigation of Graſſes with indefatigable induſtry.*)
Lin. gen. Schreb. n. 96. *Linn. fil. nov. gen. gram.* 31. *ſuppl.* 12.
Claſſ. 3. 1. Triandria Monogynia.
Nat. order of *Gramina, Gramineæ* or *Graſſes.*

GENERIC CHARACTER.

CAL. *Glume* turbinate, three or four-flowered, two-valved. *Valves* equal, wedge-ſhaped, divaricate at the baſe: *claw* incurved, linear, gradually widening, four-cleft: *ſegments* dilated in a ring and involving the florets, unequal; the ſide ones larger, lanceolate, acute; the inner or middle ones ſhorter by half, awl-ſhaped, awned. *Awn* dorſal, inſerted betwen the ſmaller ſegments, ſolitary, ſtraight, upright, longer than the valves.

COR. *Glume* two-valved: *valves* unequal: the *outer* very like the calycine glumes, awned; the *inner* very ſhort, quite ſimple or undivided, ovate, flat, awnleſs.

STAM. *Filaments* three, very ſhort. *Anthers* linear, the length of the valves.

PIST. *Germ* linear. *Style* ſimple. *Stigmas* two, villoſe at the ſide.

PER. none. Corolla unchanged, contains the ſeed till it is ripe, then gapes and lets it drop.

SEED ſingle, oblong, flat on the inner ſide, on the outer convex, pellucid, very ſmooth.

OBS. *The flower reſembles the figure of the Dianthus, with a narrow tube, and a ſpreading ſubradiate border; for the florets in the centre of the flower converge to a point.*

ESSENTIAL CHARACTER.

Cal. turbinate, two-valved, three or four-flowered: *valves* four-cleft awned at the back. *Cor.* two-valved, awned.

SPECIES.

1. Pommereullia Cornucopiæ.
Lin. ſpec. ed. Willd. 314. *ſuppl.* 105.

DESCRIPTION, *&c.*

1. This is a ſmall and very ſingular Graſs. Root creeping, fibrous, white. Leaves equitant imbricate in two rows, compreſſed, ſcarcely a finger's length, even. Culms branched, ſcarcely longer than the leaves. Spike ſubracemed, white, defended at the baſe with a leaf ſomewhat in form of a ſpathe. The whole flower or aggregate of florets reſembles in ſome meaſure a double Pink, or rather a ſhuttle-cock. The ſeed is rufous.

Native of the Eaſt Indies, where it was found by Koenig[1].

Willdenow obſerves, that in his ſpecimen the flowers are all directed one way (ſecundi.)

PER. *Capſule* three-celled, three-winged, each wing two-valved.
SEEDS ſolitary, ovate.

ESSENTIAL CHARACTER.

Cal. five-parted, ſpreading. *Pet.* four, with pilliferous glands at the tip. *Germ* three-ſided. *Capſ.* three-winged, three-celled, with one ſeed in each cell.

SPECIES.

1. Ponæa guianenſis.
Lin. ſyſt. ed. Gmel. 630.
Toulicia guianenſis. *Aubl. guian.* 359. *t.* 140.

DESCRIPTION, *&c.*

1. This is a tree, with a middle-ſized trunk of twenty or thirty feet high; and branched at the top into three diviſions, each of which is garniſhed throughout its whole length with leaves growing pretty near each other: they are of a pinnated appearance, and the leaflets are placed in nearly oppoſite rows: they are divided by a midrib, and are entire, ſmooth, green, firm, oval, and waved at the edges: the largeſt are eight inches long, and about three inches wide: the rib on which they grow is about two feet long; and is ſomewhat ſwelled at its origin; at firſt cylindric, and then triangular; the number of leaflets is eight on each ſide. The flowers, which are very ſmall, and of a whitiſh colour, are produced at the extremities of the branches on large ſpreading panicles: they are ſeſſile, and are placed on the panicle in little approximated heaps. This tree is a native of Guiana, growing near the borders of rivers, and flowering in the month of november[a].

Leaves haſtate, flowers umbelled.

DESCRIPTIONS, *&c.*

[Theſe are aquatic herbaceous perennial plants, with fibrous roots, moſtly natives of the Eaſt Indies. Both root and ſtem-leaves ſheathing, frequently ſagittate. Flowers in ſpikes or umbels terminating, or put forth from the cloven ſheath of the leaves, each having a ſpathe. Some of the ſpecies have a ſuperior or half-ſuperior germ, and are more nearly allied to the *Juncі*[b].

1. Native of ſhady moiſt places in Malabar and Cochinchina. But it belongs to the claſs *Monandria*, and is very nearly allied to *Thalia*, if it be not a ſpecies of that genus[c].

2. Root-leaves petioled, orbicular-cordate or reniform, obtuſe, veinleſs. Stem-leaf ſingle, from the ſheath of whoſe petiole iſſues a half round petiole, the length of a finger. Spathe one-leafed, ovate, permanent, terminating. Spadix hiſpid. Spike pedunculed, ovate with the flowers on pedicels, very ſhort, almoſt imbricate in a head. Corolla ſix-cleft, unequal, having the ſize and appearance of the neuter florets of *Centaurea Cyanus*, or Blue-bottle. Stamens ſix. Germ ſuperior, three-ſided. Style ſimple.—Native of Surinam[d].

3. This is a ſtemleſs aquatic plant. Root jointed, with long capillary whitiſh fibres at the joints. Leaves petioled, radical, half a foot long, roundiſh with the baſe drawn out into a thickened petiole and an acuminate tip, entire, the margin waved, ſtriated, veinleſs, nerveleſs, ſmooth. Petioles thickened, ſuberous, longer than the leaves, round, ſmooth, ſheathing at the baſe, producing the ſcape in the middle from a lateral ſheath. Scape ſhort, terminated by a looſe, ſpreading, many-flowered ſpike. Flowers alternate, approximating; under which one common ovate-cordate, blunt, open ſpathe. Corolla ſalver-ſhaped, ſix-cleft, after flowering ſexpartile, almoſt regular, blue: three of the ſegments exterior, dotted, ſomewhat rough-haired; the middle one ſuperior, wider, ovate. Filaments ſix. Anthers incumbent, haſtate at the baſe. Germ three-ſided. Style longer than the ſtamens. Stigma thickened. It bears ſome ſimilitude to *P. cordata*, but the cordate leaves in that ſpecies diſtinguiſh it very clearly[e].

Native of Jamaica, in moſt of the Lagoons and rivers about the Ferry. Browne calls it round-leafed Water-Plantain or Pontederia; and ſays that the leaves are roundiſh thick and ſmooth; the flowers moderately large; the ſtalk about an inch in diameter; that it grows luxuriantly, and throws up its flower-ſpike a good way beyond the ſurface of the water.

4. Leaves radical, cordate, acuminate, nerved, even, on very long petioles widening a little above the

[b] Juſſieu gen. [c] Swartz obſ. [d] Linn. ſuppl. [e] Swartz, deſcr.

middle or sheathing with a lateral cleft. Raceme lateral, simple, shorter than the leaf, from the sheath of the petiole, erect, but bent back when the flowering is over. Flowers four or five, alternate, on short pedicels. Petals six. Stamens six. Style club-shaped. Germ certainly superior.—Native of the East Indies in watery places*.

Thunberg, who found it about Nagasaki in Japan, describes the root as fibrous, in bundles, rust-coloured: the leaves radical, scarcely cordate, acute, entire, sinooth: petioles loose at bottom, sheathing, weak, erect, a foot long, floriferous. Stem or scape none. Flowers from the sheath of the petioles above the middle, racemed, pedicelled, directed the same way, drooping. Peduncle scarcely a finger's length. Pedicels one-flowered, a quarter of an inch in length. He found a specimen in Java with subcordate leaves, in other respects much resembling the above.

5. This is only two or three inches in height. Roots long, jointed, with whitish, capillary, aggregate fibres at the joints. *Leaves radical, emarginate at the base but scarcely cordate, entire, smooth, nerveless, an inch in length. Petioles sheathing at the base, longer than the leaves, fistular, round, smooth; from which issues, in a cleft or lateral sheath, a scape which is an inch long, round, naked, one-flowered. Spathe lanceolate, one-valved, one-flowered. Corolla blue: tube narrow, cylindrical, inclosed within the spathe: border equal, six-parted: segments lanceolate; the three upper ones all of the same blue colour; the three inner ones having a yellow spot at the base near the throat. Filaments three, inserted into the throat of the tube, short. Anthers sagittate, erect, blue, above the tube. Germ oblong, cylindrical. Style erect, the length of the tube and the stamens. Stigmas six, linear, villose. Capsule elongated, round, acuminate, within the spathe, three-celled, three-valved, three-grooved. Seeds very many, small, roundish, brown. This species is very distinct from the rest, by its one-flowered scape and spathe.

Native of Jamaica and Hispaniola on the muddy banks of rivers†.]

6. This grows naturally in marshy places in Virginia, and most parts of North America, and Dr. Houstoun found it growing plentifully at La Vera Cruz. This has a perennial root, from which arise two or three herbaceous thick stalks a foot high, each having one heart-shaped leaf about five inches long, and two and a half broad, of a pretty thick consistence. The base is deeply indented, and the two ears are rounded; the foot stalk of the leaf closely embraces the stalk like a spatha or sheath, for near three inches in length; above this is another sheath which includes the spike of flowers; this opens on one side, and the stalk rises near two inches above it, where the spike of flowers begins. The spikes are about three inches long; the flowers are blue, sit very close together, and have the appearance of lip flowers. These appear in june, but are not succeeded by seeds in England.

[Loureiro found it in the marshes of Cochinchina. According to him, the plant is almost stemless; the leaves cordate-sagittate, long, smooth, on awl-shaped petioles, two feet in length; scape naked, four feet long, spikes long, upright, terminating: corolla blue, spreading very much, six-parted; the three inner segments ovate, the three outer oblong, all of equal length.]

7. This grows naturally about Madras in watery places. It rises with a single stalk eight or nine inches high, having one arrow-pointed leaf, whose base embraces the stalk like a sheath, and from the open side of the sheath come out the flowers, which are at first inclosed in another smaller sheath: these grow in a small kind of umbel; they are composed of six acute-pointed petals which spread open. Each flower stands upon a slender foot-stalk about an inch long; the foot stalk of the leaf rises a considerable height above the flowers, so that they appear to come out from the middle of the stalk.

* Linn. mant. † Swartz, dekr.

Loureiro found this also in Cochinchina, on the banks of the river that flows through the metropolis. He describes it as almost stemless, like the preceding; the leaves subhastate, smooth, on thick, diffused petioles, two feet long; scape none; flowers blue, in a sessile umbel, bursting out near the top of the petiole which is dilated into a membrane. Partial peduncles long. Corolla superior, six-parted, unequal. Filaments six, placed upon the corolla. Capsule ovate, three-celled, many-seeded.

The sixth species was cultivated by Mr. Miller in 1759*.

PROPAGATION AND CULTURE.

6. As this plant grows naturally in moist boggy places, it is very difficult to be preserved in England; nor does the plant arise from seeds here, for I have sowed the seeds in various situations, and managed them differently, but could never get up any of the plants; but I had three or four of the plants sent me, inclosed in large clods of earth from New England, which I planted in pots, covering them with Moss, and constantly supplied them with water. With this management two of them flowered, but the following winter destroyed them, as they were not put under shelter; so that to preserve them, they should be placed under a hot-bed frame in winter, where they may be exposed to the open air at all times when the weather is mild.

7. This sort is much more difficult to preserve in England, because it is a native of hot countries, and grows always in places flowed with water. A plant of it was formerly brought over to Charles Dubois, Esq; at Mitcham, but it was not long-lived here.

Leaves fmooth on both fides acuminate ferrate deltoid, the tranfverfe diameter longer.]

5. Populus balfamifera. *Common Tacamahaca Poplar Tree.*

Lin. fpec. 1464. *fyft.* 889. *Reich.* 4. 263. *mat. med.* 215. *hort. cliff.* 460. *Du Roi harbk.* 2. 143. *Pallas roff.* 67. *t.* 41. *Gmel. fib.* 1. 152. *t.* 33. *Duham. arb.* 2. 178. *t.* 38. *f.* 6. *Mill. fig.* 174. *t.* 261. *Trew, Ehret. t.* 46.

P. Tacamahacca. *Mill. dict. n.* 6.

Leaves ovate ferrate whitifh underneath, ftipules refinous.

[6. Populus candicans. *Heart-leaved Tacamahaca Poplar Tree.*

Ait. kew. 3. 406.

Leaves cordate acuminate whitifh underneath.

7. Populus lævigata. *Smooth Poplar Tree.*

Ait. kew. 3. 406.

Leaves cordate three-nerved fmooth glandular at the bafe unequally ferrate, petioles compreffed, branches round.

8. Populus monilifera. *Canadian Poplar Tree.*

Ait. kew. 3. 406. *Abbot, Georg. t.* 71.

Leaves fubcordate fmooth glandular at the bafe, ferratures cartilaginous hooked femewhat hairy, nerves patulous, petioles compreffed, branches round.

9. Populus græca. *Athenian Poplar Tree.*

Ait. kew. 3. 407.

Leaves cordate fmooth glandular at the bafe remotely crenate, petioles compreffed, branches round.

10. Populus heterophylla. *Various-leaved Poplar Tree.*

Lin. fpec. 1464. *fyft.* 889. *Reich.* 4. 264. *Du Roi harbk.* 2. 150. *Gron. virg.* 194. 157.

Leaves cordate, the primary ones fubefcent and without any glands at the bafe, petioles roundifh, branches round.]

11. Populus angulata. *Carolina Poplar Tree.*

Ait. kew. 3. 407. *Duham. arb.* 2. 178. *t.* 39. *f.* 9. *Cateſb. car.* 1. *t.* 34.

P. balfamifera. *Mill. dict. n.* 5.

Leaves cordate fmooth, branches angular winged.

DESCRIPTIONS, *&c.*

[1. The White Poplar grows very tall, with a ſtraight trunk, covered with a ſmooth whitiſh bark. Leaves ſmooth, blackiſh green above, but having a thick white cotton underneath; they are about three inches long, on petioles an inch in length, ſtarred and grooved on each ſide: in young trees the leaves are roundiſh, but in adult ones angular, divided into three, five or ſeven lobes; they are without glands, either at the baſe or on the ſerratures. The flowers are exactly ſimilar to thoſe of *P. tremula*[a].

Native of Europe, from Sweden to Italy, alſo of Siberia and Barbary: in woods, hedges, and near rivers and brooks.

Monſ. Deſfontaines remarks that the leaves are larger than in the European tree; that the flowers are monoecous, the ſtamens from eight to thirty, the anthers twin, ſtigmas four, capſule oblong, one-celled, two-valved: his calyx is the nectary of Linneus. In all the ſpecies, except in *P. balſamifera*, the petioles are compreſſed on both ſides.

Leers diſtinguiſhes this from the Black Poplar, thus—Flowering-buds ovate, brown, ſhining; inner ſcales torn, ſcarioſe. Aments thicker, longer, from an ovate baſe cylindric. Scales of the calyx ſeminultifid; with ſimple villoſe ſegments. Stamens eight. Flowering-buds of *P. nigra* ovate-oblong, acuminate, with entire viſcid ſcales. Aments cylindric. Scales of the calyx three or four-parted, with pinnate-multifid naked ſegments. Stamens ſixteen.—Fructification in *P. tremula* the ſame as in *P. alba.*]

β. The leaves of the Abele tree are large, and divided into three, four, or five lobes, which are indented on their edges; they are of a very dark colour on their upper ſide, and very white and downy on their under, ſtanding upon foot-ſtalks which are about an inch long. The young branches of this tree have a purple bark, and are covered with a white down, but the bark of the ſtem and older branches is gray. In the beginning of april the male flowers or katkins appear, which are cylindrical, ſcaly, and three inches long, and about a week after come out the female flowers on katkins, which have no ſtamina like thoſe of the male. Soon after theſe come out, the male katkins fall off, and in five or ſix weeks after, the female flowers will have ripe ſeeds incloſed in a hairy covering, when the katkins will drop, and the ſeeds will be wafted by the winds to a great diſtance.

The leaves of the common White Poplar are rounder, and not much above half the ſize of thoſe of the Abele; the ſhoots of the Abele are paler, the katkins are larger, and the down of the ſeeds is whiter and longer.

[Mortimer ſays juſtly, that the Abele is a ſort of White Poplar, only much finer, bears a larger leaf, and makes a much ſtronger ſhoot, being a much quicker grower. He adds that the beſt ſort comes from Holland and Flanders. Hence in ſome places it is called Dutch Beech.

Samuel Hartlib, in his Compleat Huſbandman, 1659, ſays, that ſome years ago there were ten thou-

[a] Linneus, Ray, Lightf. Withering.

ſand Abeles at once ſent over into England from Flanders, and tranſplanted into many counties. This timber is incomparable, ſays he, for all ſorts of wooden veſſels, eſpecially trays; and butcher's trays cannot well be made without it, being ſo exceeding light and tough.

The fineſt Abeles I ever ſaw were in Buckinghamſhire, at Hartwell near Aylesbury, the ſeat of the late excellent Sir William Lee, Bart. They are remarkably tall, with the cleaneſt bole imaginable.

A ſpecimen of their advance; ſays Evelyn, we have had of an Abele Tree at Sion, which being lopped in February 1651, did by the end of October, 1652, produce branches as big as a man's wriſt, and ſeventeen feet in length. As they thus increaſe in bulk, their value advances likewiſe, which after the firſt ſeven years is annually worth twelve pence more. The Dutch therefore look upon a plantation of theſe trees as an ample portion for a daughter, and none of the leaſt effects of their good huſbandry; which may well be allowed, if the calculation hold of Sir Richard Weſton, who began his plantation not long ſince about Richmond; that thirty pounds being laid out in theſe plants, would render at the leaſt ten thouſand pounds in eighteen years; every tree affording thirty plants, and every of them thirty more, after each ſeven years improving twelve pence in growth, till they arrive to their *acme*.

An Abele Tree planted at Seething in the year 1760, in ſtands without roots (truncheons) ten or eleven feet long, on a bank about thirteen feet broad, with water on each ſide, at about five feet from the ground meaſure five feet to five feet nine inches in circumference, and are tall flouriſhing trees[1].

The wood of White Poplar, ſays Mr. Evelyn, is ſought of the ſculptor; and they ſaw both this and the Black into boards, which continue a long time where they lie dry. In ſword and buckler days they made ſhields of this material. They ſerve alſo for wheel-barrows, and the ſides of waggons and carts, and may be conſidered as an uſeful ſubſtitute to the Aſh[2].

The bark of the White Poplar has been recommended in the cure of intermittent fevers. It ſhould be gathered in ſummer, when the tree is full of ſap, and dried by a gentle heat. A dram of it powdered is given every four hours between the fits: and in obſtinate caſes one fifth part of Peruvian bark is mixed with it[3].

Truncheons of the White Poplar and Abele, nine feet long, and the ſize of a common hop-pole, planted in 1775, on the gravelly bank of a ſtream, ſome yards from the current, in twelve years were from twenty-four to twenty-eight inches in girth, five feet from the ground, and in height were equal to many oaks taken down for timber[4].

A White Poplar in St. John's College walks Cambridge, blown down in a hurricane on friday morning, november the ſixth, 1795, was forty-two feet in length, girted twenty-nine inches and a half, and including the three arms contained three hundred and twenty-eight feet.

It is of quick growth and bears cropping, but is unfavourable to paſturage. The wood is ſoft white and ſtringy, and makes good wainſcotting, being little ſubject to ſwell or ſhrink. Floors, laths, packing caſes and turner's ware are made of it[5]. I have ſeen beautiful floors laid with planks of the Abele.

2. The Trembling Poplar or Aſp, as it is called from the German *Eſpe*, which is the general name for all Poplars, has a green ſmooth bark. The leaves at firſt breaking out are hairy above and cottony underneath, but when full grown are ſmooth; they are ſlightly heart-ſhaped, ſmaller and more approaching to circular than in the preceding, with a few angular teeth on the edges[6]. Linneus ſays that they are rolled inwards at the edge, and that they have two glands running one into the other on the inner ſide above the baſe. He alſo obſerves from Gouan, that the leaf-ſtalks are flatted towards the end, whence the perpetual trembling of the leaves with every breath of wind. But the petioles being flat in the White and Black Poplars as well as in this, Dr. Stokes accounts better for the phenomenon, from the plane of the long leaf-ſtalks being at right angles to that of the leaves, which allows them a much freer motion than could have taken place had their planes been parallel. This trembling of the leaves has been ſo generally noticed as to have become proverbial among us; and Mr. Lightfoot informs us that the Highlanders of Scotland account for it, from a ſuperſtitious notion that our Saviour's croſs was made of this tree, and that therefore the leaves can never reſt.

Of the Aſpen, ſays Evelyn, our woodmen make hoops, fire-wood, coals, &c. and the bark of young trees, in ſome countries, ſerves for candle or torch-wood. He thruſts down a more ſearching foot, and and takes it ill to have his head cut off, as the ſame author quaintly expreſſes it. Villars alſo ſays that it will not bear lopping, like the Black Poplar.

This tree is of ſpeedy growth, and will grow in any ſituation or ſoil, but worſt in clay. It impoveriſhes the land: its leaves deſtroy the graſs, and the numerous ſhoots of the roots ſpread ſo near the ſurface, that they will not permit any thing elſe to grow. The wood is extremely light, white, ſmooth, woolly, ſoft, durable in the air. The bark is the favourite food of beavers[7]. Pannels or pack-ſaddles, canns, milk-pails, clogs, pattens, &c. are made of the wood[8].

The leaves and leaf-ſtalks ſometimes are ſet with red glandular ſubſtances, about the ſize of a pea, which are the neſts of *Tipula juniperina*.

Native of Europe, from Sweden to Italy; in moiſt woods and in boggy ground.

3. The Black Poplar has a naked lofty trunk, covered with an aſh-coloured bark, and a regular handſome head[9.] Leaves ſlightly notched on their edges, ſmooth on both ſides, and of a light green colour. [They have no glands at the baſe, but the ſerratures are glandular on the inner ſide[10]. The petioles are yelloviſh[11]. According to Linneus, the ſtamens are as many again as in *P. tremula*: Leers ſays they are ſixteen in number.] Mr. Miller obſerves that the katkins of this ſort are ſhorter than thoſe of the two former. [Capſule compreſſed a little at the top and ſomewhat acuminate, the reſt turgidly lenticular, one-celled; valves concave ſpreading horizontally. Seeds oblong roundiſh, whitiſh; waving with hairs at top four times as long as the ſeed.

This is a tree of quick growth, and on the banks of rivers, and in moiſt ſituations it grows up to a great height, throwing out numberleſs ſuckers from the roots. It loves a moiſt black ſoil, and bears cropping well. The bark, being light like cork, ſerves to ſupport the nets of fiſhermen. The wood is not apt to ſplinter: it is light and ſoft, and ſometimes uſed by turners[12]. It is incomparable, ſays Mr. Evelyn, for all ſorts of white wooden veſſels, as trays, bowls, and other turner's ware; and is of eſpecial uſe for the bellows-maker, becauſe it is almoſt of the nature of cork, and for ſhip-pumps, though not very ſolid, yet very cloſe and yet light; ſo as it may be uſed for the ſoles, as well as wooden heels of ſhoes, &c. Vitruvius reckons it among the building timbers. Likewiſe to make carts, becauſe it is exceeding light; for vine, and hop-props, and divers vimineous works[13].

It makes uſeful rafters, poles and rails, and in a proper ſoil, makes a very quick return for ſuch purpoſes[14]. It is excellent for flooring boards, and is much uſed for the purpoſes of deal in ſome of the midland counties. The boards are ſo ſlow in taking fire, that the flames are ſaid to have been ſtopped at that part of a building on fire, where this timber had been uſed. It ſmokes a long time before it burſts into a flame[15]: and of courſe is a bad wood for fuel. One

[1] Bath memoirs. 5. 445. [2] Kent's hints. [3] Bath memoirs and Philoſ. Tranſ. [4] Bath memoirs. [5] Withering. [6] Lightfoot. [7] Idem. [8] Linn. [9] Withering. [10] Light. Withering. [11] Silva, b. 1. c. 14. [12] Kent, hints 180. [13] Young's annals, v. 121. p. 64.

of the beſt uſes to which the wood of this and other Poplars can be applied is for packing-caſes[a].

The loppings in january are for the fire, where fuel is dear, but they burn untowardly, and rather moulder away, than maintain any ſolid heat. Of the twigs, with the leaves on, are made brooms. The catkins attract the bees, as do alſo the leaves, which are more tenacious of mildews than moſt foreſt trees, the oak excepted[b]. The red ſubſtance like berries, upon the leaf-ſtalks, as large as a cherry, bulging on one ſide and gaping on the other, are occaſioned by an inſect called *Aphis burſaria*. Many ſpecies of inſects are ſupported by this and the other Poplars[c].

The leaves are gathered in ſome parts of Europe, during the month of october and dried, to be given as fodder to the ſheep in winter[d].

The Black Poplar is trimmed in Italy for the vines to run on. They poll or head the trees every ſecond year, ſparing the middle ſtraight and moſt thriving ſhoot, and at the third year cut that off alſo.

The ſhade of this tree is eſteemed very wholeſome in ſummer, but it does not become walks or avenues by reaſon of the ſuckers, and that it fouls the ground at the fall of the leaf. It ſhould be planted in woods, and to flank places at diſtance, for its increaſe, and the glittering brightneſs of the foliage[e].

Mr. Evelyn mentions divers ſtately trees on the banks of the Po, as he paſſed down that river towards Ferrara; but probably theſe were the Po or Lombardy Poplar, which was not then diſtinguiſhed from the common ſort; though it is remarkable that he ſhould not obſerve the difference in the manner of growth.

The Poplar will flouriſh on almoſt any ſoils, and the large thick leaves full of rich ſweet juice fall in ſuch abundance, as ſoon to create a ſoil, fit for meadow or paſture. Thus tracts of waſte land, not dry, might in a few years be rendered fertile.

In Kamtchatka, the inhabitants are ſometimes reduced to the neceſſity of converting the inner bark into bread.

Scheffer made paper from the cotton down of the ſeeds.

The buds both of this and the White Poplar, ſmell very pleaſantly early in the ſpring, and being preſſed between the fingers yield a balſamic reſinous ſubſtance, which extracted by ſpirits of wine ſmells like ſtorax. A dram of this tincture in broth is adminiſtered in internal ulcers and excoriations, and is ſaid to have removed obſtinate fluxes proceeding from an excoriation of the inteſtines. Theſe buds give name to the *Unguentum Populneum*, which is frequently ordered to aſſwage hæmorrhoidal pains[f].

In the celebrated diſtrict of Waſe in Flanders, the whole of which is diſtributed into ſmall incloſures not more than an acre and half in extent, great quantities of White and Black Poplars are planted in the hedge-rows, ſixteen or eighteen feet aſunder; they are not ſuffered to grow to any great ſize, but are cut down every twenty or four and twenty years, and replaced by young plants of the ſame ſort: the largeſt trees are always cut down, to prevent the land from being too much ſhaded. Fifty trees are allowed to an acre, and they are generally ſold for ſeven or eight florins apiece, for making wooden ſhoes, of which they not only ſend a prodigious quantity into other provinces, but likewiſe ſupply all Holland with them[g].

The Black Poplar is a native of Europe, from Sweden to Italy; near rivers and in moiſt woods.

Pliny mentions diſtinctly theſe three ſorts of Poplar. "Populi tria genera, alba, nigra, et quæ Lybica ap-"pellatur;" the white, the black, and the Lybian or trembling Poplar. The white is called in Greek Λευκη, and the black Αιγειρος. It is well known that this tree was accounted ſacred to Hercules—"Populus "Alcidæ gratiſſima." The hero crowned his head with it, from the banks of Acheron, when he returned from the infernal regions: hence Virgil calls it, "Herculeæ arbos umbroſa corona." It was with the white ſpecies that he uſed thus to adorn himſelf; for Theocritus, in his ſecond Idyllium, calls it Λευκη—

——"Λευκαν Ηρακλειον ιερον δενδρος."

In the invitation of Galatea, in Virgil's ninth eclogue, the ſhepherd among other recommendations, mentions that a White Poplar ſhades the mouth of the cave:—

——"hic candida Populus antro
"Imminet, & lentæ texunt umbracula vites."

4. The Lombardy, Turin or Po Poplar differs from the common Black ſort chiefly in its cloſe conical manner of growth, like the Cypreſs. The leaves are greater in breadth than length, whereas in the Black Poplar the longitudinal diameter is the greateſt.

This has been eſteemed by ſome as no more than a variety of that; and indeed it can ſcarcely be conſidered as a diſtinct ſpecies.

It is recommended for the quickneſs of its growth. A correſpondent in the Gentleman's Magazine (vol. 57. p. 886.) mentions a tree of this ſort, not planted much more than ten years, forty feet high at leaſt, and four feet or more in girt, which has gained for the laſt three years from three to four inches each year in thickneſs, and has made ſhoots near four feet long. As it does not flame readily when burnt, he thinks it might be uſeful for beams and floors of houſes; but he has been informed that it decays near the ground in a few years, that the wood is not durable, and that the young ſhoots are apt to die in hard weather.

Mr. Boutcher obſerves, that it grows even faſter than the common ſorts, is propagated with equal eaſe by cuttings, is as hardy and will ſucceed in the ſame kinds of land.

A correſpondent in Young's annals aſſerts that the Italian Poplar is fit to cut for building uſes in twelve years, and that at eight years growth they are forty feet high. For rafters, ſmall beams, ſtuds, boards, &c. he ſays they have ſtood ſixteen years without the leaſt decay, having been bruſhed over with oil tar and brickduſt, laid on hot.

Dr. Anderſon, who recommends it to be tried for live fences, ſays that he has lately met with ſome facts, that ſeem to ſhow that the Lombardy Poplar is not ſuch an exceeding quick grower, or ſo valuable a tree in other reſpects, as we were made to believe when it was firſt introduced into Great Britain[h].

The quickneſs of growth depends upon the ſoil and ſituation in which it is planted. Mr. Young, in his Iriſh tour mentions ſome which grew to the height of thirty-five feet in five years, and many at two years old of twelve feet. I have meaſured one of my own trees, which has been planted about twenty-five years, and find that it meaſures ſix feet five inches round, a foot above the ground, and ſix feet, at the height of five feet; it is ſixty-three feet five inches high, and has not increaſed ſo much in height as in girt, for ſome years paſt.

For timber it ſeems to be inferior to the common Black Poplar, but it may anſwer tolerably well for floors and other purpoſes where it is not expoſed to the weather, and may prove a uſeful ſubſtitute for deal.

Mr. Songa, his Imperial Majeſty's Conſul here ſuggeſts, that though the Po or Pine-Poplar, as he calls it, ſeems regarded in this country only for its beauty and quick growth, yet in a trading country like ours it may be of ſome conſequence in packing all ſorts of dry goods. The great quantity therefore planted of late years in the neighbourhood of London may in a ſhort time turn to good account for that purpoſe.

The trunk of a Po Poplar about two feet in diameter, and thirty feet in length, which ſize it will attain in twenty years or leſs, is ſold in Lombardy to the dealers for twelve or fifteen ſhillings. They cut it at the water ſaw mills, green, into thin boards of one quarter or one third of an inch, for packers of bales of woollens, boards to put in the middle of ſilk pieces or other manufactures, and for many other uſes where a thin board is wanted. Boards of half an inch, and

[a] Marſhall, midland 2. 387. [b] Evelyn. [c] Wallerius.

[h] Eſſays, 1. 100.

planks from one to two or three inches, are alſo cut out for different uſes; but of about three quarters to an inch moſtly, for boxes and caſes to pack merchandiſe in.

The lightneſs of the wood ſaves much expenſe in the carriage: and nails do not ſplit the Poplar plank, as it frequently happens with boxes and caſes made of other wood. The Poplar gives way to the nail, and cloſes upon it afterwards. If caſes fall or are thrown carelefsly on the ground, which too often happens, this wood gives way a little, and returns to its former poſition without ſplitting; which oak and other heavy woods will not do.

In Lombardy, all the veſſels in which the grapes are carried home in carts from the vineyards, are of Poplar plank about two inches thick, and in them the grapes are ſqueezed. Such veſſels laſt thirty or forty years, and by their lightneſs are manageable, however large and long. A four-wheeled cart is in general covered with one of them, and it contains about fifteen hundred weight of grapes, each hundred being a hundred pound of thirty ounces[1].

The peculiar uſe of the Lombardy Poplar in this country has hitherto been for ornamental plantations and covering unſightly buildings. To the latter purpoſe its upright cloſe conical mode of growing, with its feathering very readily down to the very ground, particularly adapts it.

Mr. Gilpin has thought ſome of the Poplars picturesque. They are at leaſt ſtately trees, but their thin quivering foliage is neither adapted to catch maſſes of light, like the Elm, nor has it the hanging lightneſs of the Aſh. Its chief uſe in landſcape is to mix as a variety, in contraſt with other trees.

The conic form of the Lombardy Poplar, as a deciduous tree is peculiar. Among evergreens we find the ſame character in the Cypreſs; and both trees in many ſituations have a good effect. The Cypreſs often, among the ruins of ancient (and the buildings of modern) Rome, breaks the regularity of a wall, or a pediment: and the Poplar on the banks of the Po, no doubt has the ſame effect among the deciduous brethren, by forming the apex of a clump.

One beauty the Italian Poplar poſſeſſes which is almoſt peculiar to it, and that is the waving line it forms, when agitated by wind. Moſt trees in this circumſtance are partially agitated. One ſide is at reſt, while the other is in motion. But the Italian Poplar waves in one ſimple ſweep from the top to the bottom, like an oſtrich-feather on a lady's head. All the branches coincide in the motion: and the leaſt blaſt makes an impreſſion upon it, when other trees are at reſt. Although this tree ſometimes has a good effect, when ſtanding ſingle; it generally has a better, when two or three are planted in a clump[2].

The Lombardy Poplar is ſaid to have been firſt introduced into this country, in Eſſex, by the Earl of Rochford, about the year 1758, and in that county it goes by his name[3]. In France it has been cultivated ſince the year 1749[4].

5. By the growth of this tree in Europe it ſeems not to be of a very large ſize. Bark ſmooth, like that of the Black Poplar; the young branches have much the ſame appearance, but their annual ſhoots are ſeldom more than a foot in length. The leaves reſemble thoſe of the Pear tree; are about four inches long, and an inch and half broad in the middle, drawing towards a point at each end; their upper ſide is of a deep green, and their under ſide is hoary; they ſtand upon long footſtalks, and are placed without order upon the branches. The male flowers come out from the ſide of the branches in long katkins, in april and may, and fall off ſoon after; their ſtamens are numerous, irregular in height, and crowned with headed anthers of a purple colour. The hermaphrodite flowers are produced at the end of the ſhoots upon long ſlender peduncles in very looſe katkins, having a leafy involucre under each, which is oval and entire; and from the boſom of that ariſes the peduncle, which is very ſhort. Upon the top is placed the petal or calyx (or nectary, according to Linnæus,) ſhaped like a wide cup, having a large ſtyle in the centre, and two ſtamens on one ſide, terminated by pyramidal purple anthers. Theſe flowers appear in july, and are ſucceeded by oval capſules terminating in a point, and incloſing downy ſeeds. The ſcaly covers of the buds abound with a tenacious balſam in the ſpring, becoming liquid by heat. It is of a yelloviſh colour and a fragrant ſcent.

This tree is a native of Canada, and ſome other parts of North America, whence the balſam was brought to Europe. It comes over in ſhells, and is ſmooth, of an even texture, and in colour like ſtrained Galbanum, but lighter.

From Canada it was brought to the iſland of Jerſey, and was propagated there. Six of the plants were ſent from thence to Caroline Queen conſort of King George II, in the year 1731, by the title of *Arbre de la Reine*. One of theſe was given by the Queen to Sir Hans Sloane, and was planted in the botanic garden at Chelſea. This produced male katkins ſeveral years, but produced none of the female or hermaphrodite flowers until the year 1760 or thereabouts. It does not appear that this tree has been long in France; for Monſ. Duhamel mentions it to have been lately planted there, and that it had ſupported the winter of 1754, which had killed many other trees[5].

Mr. Miller's figure and deſcription agrees with the American Tacamahaca as it appears in our gardens. The former repreſents the male aments. Pallas's figure gives the female aments; it has much wider leaves; but he adds a leaf of a Daurian variety with a longer ovate leaf, more like ours; and of an Altaic variety, with a lanceolate leaf.

The trunk of the tree, in Siberia is ſtraightiſh, not tall, covered with an aſh-coloured bark; the wood reddiſh, cloſer and a little harder than in the common Poplars. The branchlets in the Altaic tree are more ſlender, and rod-like; in the Daurian thick, ſhort, knobbed and wrinkled, with a yellow ſkin ſometimes of a very deep colour. Leaves in the rod-like variety ovate-acuminate, in the Altaic commonly lanceolate; in the common Daurian ovate and thicker, ſo as to be in a manner coriaceous; in both very ſharp, ſerrate, quite ſmooth, ſhining as if varniſhed, deep green above, pale underneath. Aments terminating, thick, the female ones ripening in june; containing ovate thick rugged capſules, ſubcalycled with the receptacle, ſcarcely peduncled.

The buds of this tree, from autumn to the leaſing ſeaſon are covered with abundance of a glutinous yellow balſam, which often collects into drops, and is preſſed from the tree for medical uſe. It diſſolves in ſpirits of wine; and the inhabitants of Siberia prepare a medicated wine from the buds, which is diuretic, and eſteemed by them ſerviceable in the ſcurvy. The Grous and other birds of that family feeding on theſe buds during winter, acquire a flavour which is much eſteemed in that country.

This tree occurs firſt, in Siberia, in the upper region of the river Irtis, by the Uba, Ulba, and other ſtreams of the Altaic chain. It is more abundant in eaſtern Siberia, eſpecially in the channels of the Jeniſea and Daurian rivers. On gravelly banks it grows to a conſiderable ſize, but with a ſhort trunk; in ſubalpine ſituations it is taller; in the moiſt plains of Dauria it is ſhrubby, becauſe the graſs is fired there, and the twigs of the former year being thus deſtroyed, it cannot riſe into a trunk[6].

6. This alſo is native of Canada, and is reſinous like the preceding; but the leaves are different, being hollowed next the petiole and drawn out at the point. It flowers earlier, namely in march. Introduced about 1772, by John Hope, M. D[7].

7. Native of North America. Cultivated in 1769, by Hugh Duke of Northumberland. It flowers in march and april.

8. Native

8. Native of Canada; introduced about 1772 by John Hope, M. D. It flowers in may [4].

It appears by Mr. Abbot's fine work on the Province of Georgia, edited by Dr. Smith, that this ſpecies is not confined to Canada.

9. This reſembles the next ſpecies in growth and foliage.—Native of the iſlands of the Archipelago. Cultivated in 1779, by Hugh Duke of Northumberland. It flowers in march and april.

10. A large tree; branches numerous, veined and angular; leaves broad and ſlightly ſerrate: flowers in looſe aments, making little ſhow.—Native of Virginia and New York. Cultivated in 1765 by John Fothergill, M. D. It flowers in april and may [1].

11. Shoots very ſtrong and generally cornered, covered with a light green bark like ſome ſorts of Willow. The leaves upon young trees, and alſo upon the lower ſhoots are very large; but thoſe upon older trees are ſmaller: as the trees advance their bark becomes of a lighter colour, approaching to gray. The aments are like thoſe of the Black Poplar; and the anthers are purple. It grows naturally in Carolina, where it becomes a very large tree. [I have ſeen ſome of a very conſiderable ſize in England.—It was cultivated by Mr. Miller in 1759; and flowers in march [2].]

PROPAGATION AND CULTURE.

Theſe trees may be propagated either by layers or cuttings, which will readily take root, as alſo from ſuckers, which the white Poplars ſend up from their roots in great plenty; but theſe are leſs valuable than thoſe propagated by cuttings, being more liable to ſend up ſuckers. The beſt time for tranſplanting theſe ſuckers is in october, when their leaves begin to decay. Theſe may be placed in a nurſery for two or three years to get ſtrength, before they are planted out where they are deſigned to remain; but if you intend to propagate them from cuttings, it is better to defer the doing of that until february, at which time you may plant truncheons of two or three feet long, thruſting them about a foot and a half into the ground. Theſe will readily take root, and if the ſoil be moiſt in which they are planted, they will arrive to a conſiderable bulk in a few years.

The Black Poplar is not ſo apt to take root from large truncheons, therefore it is the better method to plant cuttings about a foot and a half in length, thruſting them a foot deep into the ground; theſe will take root very freely, and may be afterward tranſplanted where they are to remain. This ſort will grow upon almoſt any ſoil, but will thrive beſt in moiſt places.

I have planted cuttings of this tree, which in four years have been bigger in the trunk than a man's thigh, and near twenty feet in height, and this upon a very indifferent ſoil; but in a very moiſt ſoil, it is common for theſe trees to ſhoot eight or ten feet in a ſeaſon; ſo that where a perſon hath a mind to make a ſhelter in a few years, there is ſcarce any tree ſo proper for that purpoſe as this; but they ſhould not be planted too near the pleaſure-garden, becauſe the katkins and down which fall from theſe trees, will make a prodigious litter in the ſpring.

The white ſorts, as alſo the Aſpen-tree, likewiſe cauſe a great litter in the ſpring, when their katkins and down fall off; and their roots being very apt to produce a large quantity of ſuckers, eſpecially thoſe trees that came from ſuckers, they are unfit to be planted near a houſe or garden; but when they are interſperſed with other trees in large plantations, they afford an agreeable variety, their leaves being very white on their under ſides, which, when blown with the wind, are turned to ſight.

A conſiderable advantage may be made by planting theſe trees upon moiſt boggy ſoils, where few other trees will thrive. Many ſuch places there are in England, which do not at preſent bring in much money to their owners; whereas, if they were planted with theſe trees, they would, in a very few years, overpurchaſe the ground, clear of all expence; but there are many perſons, who think nothing except Corn worth cultivating in England; or if they plant timber, it muſt be Oak, Aſh, or Elm; and if their land be not proper for either of theſe, it is deemed little worth; whereas if the nature of the ſoil was examined, and proper ſorts of plants adapted to it, there might be very great advantage made of ſeveral large tracts of land, which at this time lie neglected.

The wood of theſe trees, eſpecially of the Abele, is very good to lay for floors, where it will laſt many years; and for its exceeding whiteneſs, is by many perſons preferred to Oak; but being of a ſoft contexture, is very ſubject to take the impreſſion of nails, &c. which renders it leſs proper for this purpoſe: it is alſo very proper for wainſcotting of rooms, being leſs ſubject to ſwell or ſhrink, than moſt other ſorts of wood; but for turnery ware, there is no wood equal to this for its exceeding whiteneſs, ſo that trays, bowls, and many other utenſils, are made of it; and the bellows-makers preſer it for their uſe, as do alſo the ſhoemakers, not only for heels, but alſo for the ſoles of ſhoes; it is alſo very good to make light carts, and the poles are very proper to ſupport Vines, Hops, &c. and the lopping will afford good fuel, which in many countries is much wanted.

[Spring is the beſt ſeaſon for planting the cuttings; though they will grow if planted in any of the winter months. They ſhould all be vigorous ſhoots of the laſt year, or at leaſt not older than two years; a foot and half in length. Plant them ten inches or a foot in the ground, in rows two feet and a half or a yard aſunder, and a foot or eighteen inches from each other. Look over the plants in ſummer, to nip off all ſide ſhoots. In two years they may be planted out, if they are for ſmall woods or ſpinneys, in boggy or watery grounds. If they are for ſtandards, they may remain in the nurſery another year; and when planted out, they will be worth in twenty or thirty years as many ſhillings each.

To form a coppice of theſe trees, if the land be not ſo boggy but that it may be ploughed, a crop of oats or other grain may be got off it the year preceding the planting, and in the autumn it ſhould be ploughed again. Let two year old plants from the nurſery be planted one yard aſunder. Hoe down the weeds the firſt year: afterwards they will require no farther trouble till the time of cutting, which may be in ſeven years; and every four or five years after, they may be cut for poles, firewood, &c. By theſe means boggy or marſhy land will often produce more than the beſt paſture. If the ground will not admit of ploughing and ſowing, the plants muſt be ſet in holes at the ſame diſtance.

For timber trees they may alſo be planted a yard aſunder, and when the heads begin to interfere, every other tree may be taken away, or the weakeſt and leaſt thriving: and thus you may continue to thin them as often as they are too cloſe.

After they are finally planted out, never ſtrip them up or take off any ſide branches [3].]

5. The Tacamahacca ſends up a great number of ſuckers from the roots, by which it multiplies in plenty, and every cutting which is planted will take root; ſo that when a plant is once obtained, there may ſoon be plenty of the plants raiſed.

[The cuttings ſhould be planted the middle of february, in rich mellow earth, ſhaded from the mid-day ſun, and watered in dry weather. The ſucceeding february remove them; ſmooth the extremities of their roots, cut off the ſtrong ſide branches, and plant them in rows three feet diſtant, and eighteen inches aſunder in the row: here let them continue two or three years, when they may be tranſplanted to the places where they are intended to remain.

It will grow on almoſt any ſoil; and when there are void ſpaces in plantations, occaſioned by the death of other trees, this will ſooner and better ſupply their places than moſt others [4].]

11. The Carolina Poplar may alſo be propagated by cuttings or layers; the latter is generally practiſed by the nurſery gardeners, being the ſureſt method;

[4] Hort. kew. [1] Idem. [2] Idem. [3] Hunter in Evelyn's ſilva. [4] Boutcher.

and thoſe plants are not ſo full of moiſture as thoſe raiſed by cuttings, ſo are leſs liable to be cut down by the froſt when young: as they are very apt to be, to a conſiderable length. As the trees grow older, the ſhoots are more woody, and not ſo liable to this diſaſter. They ſhould however be planted in a ſheltered ſituation, for their leaves being very large, the wind has great power over them; and the branches, being tender, are frequently broken or ſplit down by the winds in ſummer, where they are much expoſed.

POPULUS. See *Ceccoloba*.

PORANA.

Lin. gen. Reich. n. 230. *Schreb. n.* 286. *Juſſ.* 420. *Burman.*

Claſſ. 5. 1. Pentandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* lanceolate, blunt, commonly ſhorter than the corolla, ſpreading, permanent: in the fruit larger.

COR. one-petalled, bell-ſhaped, half-five-cleft, erect, acute.

STAM. *Filaments* five, capillary, ſpreading, commonly ſhorter than the corolla. *Anthers* incumbent, oval.

PIST. *Germ* ſuperior, ſubglobular. *Style* ſemibifid, longer than the corolla, briſtle-ſhaped, permanent. *Stigmas* capitate.

PER. two-valved.

SEED.

ESSENTIAL CHARACTER.

Cal. five-cleft: in the fruit larger. *Cor.* bell-ſhaped. *Style* ſemibifid, longer, permanent. *Stigmas* globular. *Per.* two-valved.

SPECIES.

1. Porana volubilis.

Lin. ſyſt. 200. *Reich.* 1. 433. *mant.* 560. *Burm. ind.* 31. *t.* 21. *f.* 1.

DESCRIPTION, *&c.*

Leaves diſtant, ovate, ſerrate, ſcarcely ſharp, plaited. Flowers panicled: are not ſome of them male and apetalous[1]?—Native of the Eaſt Indies.

It is a ſmooth twining ſhrub, with alternate leaves. Compare it with the *Borragineæ* and *Ehretiæ*[2].

PORAQUEIBA. See *Barreria*.

PORELLA. (*So named from the number of pores on the capſule.*)

Lin. gen. n. 1186. *Reich. n.* 1303. *Schreb. n.* 1616. *Dill. muſc.* 459.

Claſſ. 24. 1. Cryptogamia Miſcellaneæ: ſed Muſcis (ord. 3.) reſtituenda.

Capſ. oblong, opening with many lateral pores. *Calyptra* none.

OBSERVATION.

Dillenius, who eſtabliſhed this genus, was miſled by an imperfect ſpecimen; and Linnæus adopted it from him, without having ſeen the plant. Mr. Dickſon, with his uſual ſagacity and accuracy, has aſcertained it to be a *Jungermannia*, and has named it *J. Porella*. He has both deſcribed and figured it. It is a native of Pennſylvania*.

POROPHYLLUM. See *Cacalia*.

Claſſ. 18. 4. Polyadelphia Polyandria.

Nat. order of *Lauri*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, coloured, permanent, ſix-parted: *ſegments* ovate, obtuſe, the three inner leſs.

COR. none.

Nectary of nine ſcales, oblong, truncate; ſix outer, inſerted at bottom into the ſegments of the calyx, and incumbent on them: three inner faſtened to the receptacle, obverſe to the former: each having four pores; the outer ones on the inner ſide, the inner ones on the outer ſide.

Glands ſix, roundiſh, fleſhy, growing to the bottom of the calyx, between the inner and outer ſcales of the nectary. *Aublet.*

STAM. *Filaments* thirty-ſix, faſtened to the ſcales of the nectary, each proceeding from each pore. *Anthers* roundiſh, compreſſed, peltate.

PIST. *Germ* ovate, angular, immerſed in the receptacle. *Style* ſhort. *Stigma* obtuſe, concave.

PER. *Drupe* turbinate, faſtened to the calyx. *Rolander. Capſule* roundiſh, four or ſix-celled, covered with the calyx. *Aublet.*

SEEDS two. *Roland.*—very many, extremely ſmall. *Aubl.*

ESSENTIAL CHARACTER.

Calyx ſix-parted, unequal. *Corolla* none. *Filaments* nine, with four anthers on each. *Capſule* covered, four or ſix-celled, many-ſeeded.

SPECIES.

1. Poroſtema guianenſis.

O. guianenſis. *Aubl. Guian.* 2. *p.* 780. *t.* 310.

DESCRIPTION, *&c.*

1. A tree which riſes thirty feet high; branching at top: the branches cornered, ſtraight, and horizontal; leaves alternate, ovate-lanceolate, perfectly entire; ſmooth above and green, beneath ſilky and hoary; ſeated on a ſhort footſtalk which is ſwelled at its baſe, and is ſtretched and prominent as far as the axil of the leaf. The flowers are whitiſh, ſmall, paniculated, terminal, and axillary, and exhale a very pleaſant odour. It flowers in Guiana in april, where it is found in woods*.

PORRUM. See *Allium*.

PORTESIA OVATA *Cavanilles.* See *Trichilia pallida*.

PORTLANDIA. (*So named by Dr. Patrick Browne after the Dutcheſs of Portland, who was a great lover of Botany, and well acquainted with Engliſh plants.*)

Silacoides lauri folio flore carneo. *Barrere, equin.* 67.

Flowers hexandrous, tube ſubincurved, peduncles ternate, leaves ovate, calycine leaflets lanceolate. Sm.

DESCRIPTION, *&c.*

1. Leaves at the tops of the branches, approximating, elliptic, petioled, quite entire, very ſmooth. Stipules dilated, with a point. Flowers axillary, ſolitary, peduncled. Germ inferior, four-cornered, terminated by four, awl-ſhaped, ſhort calycine teeth. Corolla longer, club-ſhaped, four-cornered, white, with a four-cleft border. Anthers long, linear, not exceeding the border.—Native of Savage-iſland in the South Seas[b].

2. This is a ſhrub two or three feet in height, erect, branched. Branches and branchlets round, ſmooth. Leaves oppoſite, ovate or ſuboval, ſcarcely acuminate, quite entire, nerved, ſmooth, ſhining, underneath veined, paler, ſomewhat wrinkled, with a convex margin, three inches long, two inches wide. Petioles ſhort, thick, from round flatted a little, ſmooth. Stipules interpoſed between the leaves, broad-ovate, acuminate, preſſed to the ſtem. Flowers axillary, ſolitary, ſcarlet, on peduncles a little longer than the petioles, angular, ſmooth, coloured. Calycine leaflets acute, coloured. Corolla club-funnel-form, three inches long; tube five-cornered, at top ventricoſe; border five-cleft, ſegments ovate-acute, erect. Filaments the length of the tube, erect, equal. Anthers longitudinal, very long, ſpiral, yellow. Germ oblong, five-cornered, ſmooth. Capſule roundiſh, crowned with the calycine leaflets, ſmooth, coloured.

It differs from the *grandiflora* in having the leaves nearly roundiſh or oval, coriaceous, veined underneath; the corollas ſmaller by half, and of a full ſcarlet colour; the capſules roundiſh.

Native of Jamaica, in the weſtern parts, on precipices of the mountains, but not common. It flowers there in june and july[c].

3. Stem ſhrubby, upright, branched, knotty, with a ſmooth bark cracking longitudinally. Branches oppoſite, ſpreading, round, ſcarcely divided, leafy, covered with ſmooth green bark. Buds gummy. Leaves oppoſite, ſpreading, ſomewhat lengthened at the point, equal at the baſe, entire, very ſmooth, paler beneath, marked with alternate veins projecting on both ſides. Footſtalks very ſhort, thick, round below but flatriſh above. Stipules between the leaves, connate, triangular, pointed, very ſmooth, pale, cloſely preſſed to the branch. Flowers axillary, moſtly ſolitary, between the ſtipules, peduncled, a little nodding, very large, white, beautiful, moſt fragrant at night, in the bud yellowiſh tipped with red. Peduncles ſhortiſh, round, ſmooth. Bractes none. Calycine leaflets ovate, pointed, a little curved backwards, keeled at the baſe, reddiſh towards the top. Tube of the corolla with five ſharp downy angles, inflated at the top: limb in five nearly equal ſomewhat triangular ſegments, margins ſpreading, at length revolute. Filaments on the germ, ſcarcely ſo long as the tube, downy at the baſe. Anthers very long, vertical, ſtraight. Germ ſmooth. Style a little longer than the ſtamens, declined, ſpiral, angular. Stigma at length trifid; ſegments revolute[d]. Capſule ſubturbinate, crowned with the leaflets of the calyx ſpreading very much, coriaceous, unequally five-cornered, ribbed at the corners; partition thin. Seeds elliptical, thickiſh, flat on both ſides, having raiſed dots ſcattered over them, ruſeſcent, horizontal, with an umbilicus, before they are fully ripe, fleſhy, white, of a ſharp-pointed pyramidal form, faſtened to the partition[e].

Mr. Saliſbury ſuſpects that the plant deſcribed above agrees in its generic characters with *Cateſbæa*. This cannot be denied with reſpect to the flower: but Cateſby ſays, the fruit is a berry with a ſingle cell. His authority however is but ſlight.

Jacquin's ſynonym ſeems doubtful on account of the inequality at the baſe of the leaves in his figure, which is never the caſe in our plant; nor is it found in any ſpecimen of Portlandia in Sir Joſeph Banks's herbarium.

This ſpecies, as well as the next, has occaſionally ſix ſtamens, and ſix diviſions of the flower.

Dr. Browne gathered it among rocks at the foot of mountains in Jamaica plentifully[f].

Notwithſtanding the difference in the leaves obſerved by Dr. Smith in Jacquin's figure, I cannot but think that this celebrated author intended the ſame ſpecies with that of Browne. Swartz celebrates Browne's figure as very good, and ſo it is in general; but Jacquin obſerves that the filaments are not made to ſpring from the baſes of the tube, and that the draughtſman has repreſented the excrements of inſects for ſeeds, and that he ſeldom could find the real ſeeds, even in unripe fruit. He mentions the very grateful and refreſhing odour of the flowers in the evening.

It was introduced in 1775 by —— Ellis, Eſq. and flowers in july and auguſt[g]. It is rare in the Engliſh gardens, but very frequently flowers at the Marchioneſs of Rockingham's[h].

4. This is a ſhrub, ſix feet in height, upright, divided into branches that are round, but at the origin of the peduncles compreſſed, rugged with ſmall warts ſcattered over them. Leaves ovate, quite entire, ending in a bluntiſh point, very ſmooth, veined, petioled, oppoſite, five inches long. Common peduncles three-flowered, the axillary ones ſolitary, the terminating ones in threes: the pedicels ſhort. Flowers handſome, ſweet, numerous, near three inches in length; the petals fleſh-coloured on the outſide, white within, marked with lines. Capſules brown variegated with aſh-coloured dots. The ſeeds are moſtly eaten by inſects[i]. Jacquin however found ripe ſeeds in april. It flowers in auguſt and ſeptember. Native of woods and coppices about Carthagena, Guiana and Cayenne.

PROPAGATION AND CULTURE.

3. This may be increaſed either by ſeeds or cuttings. The ſeeds, when they can be obtained, may be ſown in pots in light earth, and plunged in the tan-pit. The cuttings do not ſtrike very eaſily. The plants muſt be managed in the ſame way as other woody plants from Jamaica, and require a ſtove heat.

PORTULA. See *Peplis*.

PORTULACA (*of Pliny, by the Greeks λαπαγυν. According to ſome, it ſhould be writ,* Portulata, *quia foliis portulas imitatur. Leaves obovate flattiſh, peduncles racemed, calyxes five-leaved, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

1. Common Purſlane is an annual herbaceous plant, with a round, ſmooth, procumbent, ſucculent ſtem, frequently red, and diffuſed branches, often throwing out fibres at the joints. Leaves more or leſs wedge-ſhaped, oblong, blunt, fleſhy, ſmooth, quite entire, ſeſſile, cluſtered, eſpecially at the ends of the branches. Flowers ſeſſile, ſcattered: corollas yellow, ſpreading; petals ſubtruncate at the tip and emarginate. Stamens ten. Capſule one-celled, opening horizontally. Seeds round, black, very ſmall[a].

The ſtamens vary in number: according to Haller they are from eight to fifteen; Gmelin ſays, from ſix to twelve and more; Villars twelve. Haller and Scopoli attribute five ſtyles to it; and Gmelin ſays that the ſtigma is four-parted. According to Linneus the flowers open from eleven to twelve: Pollich affirms, that he has ſeen them open at nine a. m.

Native of both Indies, China, Cochinchina, Japan, the iſland of Aſcenſion, &c. and now in many parts of Europe. We learn from Turner, that it was cultivated here in 1562[b]. This is our earlieſt written authority; but we probably had it earlier, ſince it was formerly much in requeſt as a wholeſome ſalad and pickle, and as a medicine for various diſorders. But it is now little uſed.]

β. Garden Purſlane differs from the wild, only in having larger and more ſucculent leaves. If it be permitted to ſcatter the ſeeds, in two years it will become in every reſpect like the wild plant.

There are two other varieties; one with deep-green leaves; and the other with yellow leaves, which is called Golden Purſlane; but they are only ſeminal variations.

2. This alſo is an annual herbaceous plant, with very ſucculent ſtalks, of a purple colour, and branching out greatly: the lower branches lie near the ground, but thoſe above are more erect. Leaves narrow, of a lucid green. At the joints are tufts of white hairs, and between theſe come out the flowers, of a fine pink colour, but of ſhort duration, ſeldom continuing open longer than five or ſix hours. They are ſucceeded by ſhort roundiſh capſules, filled with ſmall black ſeeds.

[The capſule is half inferior, covered by the permanent, ſhrivelled corolla as with a veil, of an oblong ſpheroidal form, girt round the middle with a prominent rim, one-celled, cut tranſverſely: the valves hemiſpherical, nearly equal. Receptacles five, free, diſtant, filiform, branched, erect, faſtened to the bottom of the capſule. Seeds kidney-form with a beak, ſhagreened as it were with very minute ſharp tubercles diſpoſed in parallel rows. The receptacles diſtinguiſh this genus from all others[c].

Linneus remarks, that the leaves are alternate, except that the terminating or floral ones are eight together in a ring: that the flowers are ſeſſile and terminating, with a biſid calyx; that there are fifteen ſtamens; and that the ſtyle is five-cleft.

Native of the Weſt Indies. Browne ſays, it is cultivated in many of the gardens about Kingſton in Jamaica, where it has been introduced, on account of its conſtant greenneſs, and the frequent ſhooting of its flowers. It is a native of the Keys, or ſmaller ſandy iſlands beyond Port-Royal; and grows in ſpreading tufts or beds about the root. All the parts of the plant are very bitter, and frequently uſed by the poorer people as a ſtomachic, &c.

[a] Loureiro. [b] Hort. kew. [c] Gærtner.

It

It was cultivated here in 1690, in the Royal garden at Hampton Court [a].

3. Root annual, fibrous. Stems annual, proſtrate, numerous, round, even, alternate, branched, half a foot long, with rooting, hairy joints. Leaves oppoſite, ſpreading, diſtant, ovate-lanceolate, fleſhy, even, ſeſſile, quite entire, concave underneath, with tranſparent *mica* ſcattered over them. Flowering petioles terminating, but when adult becoming lateral, one-flowered, thickened at top, the length of the leaves, terminated by four ſpreading cruciate bracteæ, reſembling the leaf. Flowers ſeſſile, yellow, ſurrounded with white hairs, like the joints. Calyx two-valved, membranaceous, ovate. Corolla four-parted, ovate-oblong, ſtrivelling. Filaments eight, briſtle-ſhaped, curved outwards at the baſe, the length of the corolla. Anthers roundiſh. Germ inferior, rounded. Style cylindric, thicker at top, the length of the ſtamens. Stigmas four, oblong, blunt, recurved, pubeſcent. Capſule ovate, ſlightly four-cornered, ſharpiſh, one-celled, opening tranſverſely. Seeds roundiſh, muricate.

Native of Egypt [b]:—of the Eaſt Indies. Introduced by Sir Joſeph Banks [b].

4. This grows in beds, and ſpreads a little upon the ground, but the ſtems ſeldom exceed two or three inches in length: the leaves are diſpoſed pretty thick at the top of the branches, and the flowers blow in the centre of them. There is a ſort of cotton ſhoots about the flowers, as it grows old, which in time ſpreads over moſt parts of the plant [c]. The calyx is two-leaved; and the capſule opens tranſverſely [c]. It is an annual plant; native of Jamaica.

5. This is a ſhrubby plant, two feet high. Stems round, woody at bottom, ſmooth, branched, from procumbent erect. Leaves oblong or ſubovate, attenuated at the baſe, ſhining, thickiſh, emarginate with a point, convex or flat, with the ſides often rolled back, brittle, ſcattered alternately. Peduncles at leaſt two-flowered, erect, triangular, terminating. Flowers pretty, but without ſcent, with a bifid calyx, and yellow petals. The capſule opens perpendicularly in three parts.—Native of the Weſt Indies, on rocks by the coaſt [a].

6. This was received by Jacquin under the name of P. triangularis. The ſeeds ſown in a ſtove ſucceeded well, and produced ſeveral flouriſhing plants. It agrees in general appearance with P. triangularis, Jacq. hiſt. ſtirp. amer. From a branching root ariſes a fleſhy ſtem of the thickneſs of one's thumb or more; upright, two feet high, and more: perennial, branching, purple below the leaves; the remainder green: it is round, but obſcurely angular to the touch: the younger branches are apt to be nipped by the froſt and to wither: the leaves are lanceolate, obtuſe, or a little ſharpened; and ſometimes emarginate; thick, veinleſs, alternate, ſubſeſſile, perfectly entire, rather attenuated towards the baſe. Racemes triangular, upright, either ſimple or branched, many-flowered, terminal; and at the ſides of theſe new branches ariſe. Flowers inodorous, pedunculated; calycine leaves ovate, acute, concave, whitiſh and tranſparent. Petals red; thrice the length of the calyx, extremely obtuſe. Filaments about thirty, reddiſh, and with glandular hairs. Anthers yellow. Stigma trifid, and deep purple. Capſule globoſe. The whole plant is very ſmooth [c].]

7. This has a ſhrubby ſtalk, four or five inches high. Leaves thick and ſucculent. At the top of the ſtalk comes forth a ſlender peduncle about two inches long, ſupporting four or five red flowers, appearing in july, but not ſucceeded by ſeeds in England. [The axils of the leaves are hairy; and the ſucculent leaves unite this with the Portulacas, although it has very many ſtamens, and a three-valved capſule. The calyx is two-leaved.

Native of the Cape of Good Hope [a]. Cultivated in 1732, by James Sherard, M. D. [d]

8. This alſo is ſhrubby. Stems round, woody at bottom, ſmooth, brittle, ſuberect. Leaves oval, acute at both ends, thick, fat to the touch, quite entire, petioled, alternate; the lower three inches long, the upper gradually ſmaller. Panicle a foot long, ſpreading, erect, terminating. Flowers ſmall, numerous, red, without ſcent. Calyx bifid, concave. Stamens at leaſt fourteen, equal to the corolla. Stigmas three, thickiſh. Capſule roundiſh, obſoletely three-cornered, perpendicularly three-valved [e].

Stem a foot high, flexile; with alternate, even, four-cornered branches; the lower ones longer. Leaves ſubpetioled, half an inch long, quite entire, keeled, brittle. Panicle elongated; with filiform, dichotomous pedicels. Calyx two-leaved, red. Petals five, ovate, red. Anthers yellow. Styles three. Capſule globular, one-celled, three-valved, with the valves doubled. Seeds ſeveral, black. It is quite diſtinct from *P. fruticoſa*, which has white flowers and a five-leaved calyx [f].

Native of the Weſt Indies. Introduced in 1776, by Chevalier Murray [g].

Cavanilles, who following Adanſon and Juſſieu ſeparates this from the Portulacas under the name of *Talinum reflexum*, ſays that the ſtem ſometimes periſhes, and accordingly he marks it as biennial, that the calyx is monophyllous, and the corolla is deep yellow. But plants that are perennial in their native ſoil, frequently die in a ſhort time in our ſtoves. Jacquin might poſſibly take a calyx deeply bifid for a two-leaved one, and as for the colour of the corolla we cannot depend much on that. I am inclined to prefer deſcriptions of plants made on the ſpot, or from ſpecimens gathered in places where they grow naturally, to ſuch as are formed from the plants as they appear in our ſtoves.

9. This is allied to the preceding, but is diſtinguiſhed from it by the peduncles being thicker, and the lower ones having the flowers in threes and pedicelled, at the tip [h].—Native of Egypt.

10. Annual. Stems the ſtature of *Sedum acre*, filiform, herbaceous, creeping, jointed, branched, round, looſe, red: the joints are rooting, and have a few hairs ſcattered over them. Leaves elliptic-lanceolate, even, ſomewhat fleſhy, terminating, oppoſite by pairs or by fours. Flowers yellow, ſolitary, ſurrounded by wool and four leaves. Calyx two-valved, very tender: leaflets ovate, acute, red. Stamens four to eight, but inconſtant.

Native of the Eaſt Indies; flowering from twelve at noon through the day [c].

11. Stem ſhrubby, decumbent: branches angular, covered with the ſame bloom as the whole plant. Leaves alternate, petioled, remote, quite entire, ſomewhat waved, veinleſs, thickiſh. Racemes from the uppermoſt axils, with an awl-ſhaped ſcale on the ſide oppoſite to the pedicel. Calyx five-leaved. Capſule five-valved [c].—Native of Egypt.

12. The leaves are round and ſucculent, all diſpoſed about the bottom of the ſtalk, which riſes generally to the height of ſixteen or twenty inches [i].—Calyx five-leaved. Corolla white. Capſule three-valved [k]. Native of Jamaica. Browne ſays it is a beautiful plant, and grows in a gravelly ſoil in the road through Cambridge hill.

GENERAL OBSERVATIONS.

The capſule in the five firſt ſpecies is cut tranſverſely or horizontally, which Linnæus calls *circumciſſa*; in the reſt it divides vertically into three valves, except in the eleventh which is five-valved. Hence the diviſion into two genera by Adanſon, Juſſieu and Cavanilles. But it is very well remarked by the younger Linnæus, that *Portulaca* is an exceedingly polymorphous genus in the fructification and number of parts.

The four firſt ſpecies and the tenth are herbaceous; the reſt are ſhrubby. Cavanilles indeed conſiders the eighth as herbaceous; but Jacquin as ſhrubby.

[a] Hort. kew. [b] Browne. [c] Jacquin, hort. [d] Linn. mant. [e] Linn. [f] Jacquin, amer. [g] Linn. [h] Hort. kew. [i] Jacquin. [k] Vahl. [l] Linn. mant. [m] Linn. ſuppl. [n] Linn. ſyſt. [o] Vahl. [p] Hort. kew. [q] Browne.

The calyx in the eleventh and twelfth is five-leaved; in the reſt it is two-leaved or deeply bifid.

The corolla is four-cleft in the third ſpecies; five-cleft in the fourth—the reſt have probably five petals.

The filaments vary exceedingly in number. The firſt ſpecies has from ſix to fifteen; the ſecond has fifteen; the third and fourth have eight; the eighth has ſixteen; the tenth has from four to eight; and the twelfth has from twelve to eighteen.

The following table will diſcriminate the ſpecies at one view:

I. Capſule cut tranſverſely. 1 to 5.
- Herbaceous. 1 to 4.
  - Corolla five-petalled. 1. 2.
    - Stamens ſix to fifteen. N. 1.
    - Stamens fifteen. N. 2.
  - Corolla four-cleft. N. 3.
  - Corolla five-cleft. N. 4.
- Shrubby. N. 5.

II. Capſule opening vertically, 6 to 12.
- In threes valves. 6 to 10 and 12.
  - Shrubby. 6 to 9 and 12.
    - Calyx two-leaved or deeply bifid. 6 to 9.
      - Leaves lanceolate flat. N. 6.
      - —— ovate gibbous. N. 7.
      - —— lanceolate-ovate flat. N. 8.
      - —— wedge-ſhaped flat. N. 9.
    - Calyx five-leaved. N. 12.
  - Herbaceous. N. 10.
- In five valves. N. 11.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds upon a bed of rich light earth during any of the ſummer months; but to have it early in the ſeaſon, it ſhould be ſown upon a hot-bed. This ſeed being very ſmall, little of it will be ſufficient for a family. Keep the plants clear from weeds, and in dry weather water them two or three times a week. In warm weather they will be fit for uſe in ſix weeks. To continue a ſucceſſion, ſow three or four times, at the interval of a fortnight or three weeks.

If the ſeeds are intended to be ſaved, leave ſome of the earlieſt plants for this purpoſe, drawing out all ſuch as are weak, or have ſmall leaves. When the ſeeds are ripe, cut up the plants, and ſpread them upon cloths to dry; then beat out the ſeeds and ſift them, to clear them from the leaves and ſeed-veſſels.

2, &c. The other ſorts, being too tender to live in the open air, muſt be kept in pots and placed in the dry ſtove or tan-pit, according to the country whence they come. The herbaceous ſorts are propagated by ſeeds, and the ſhrubby ones by cuttings. The ſeventh may be treated in the ſame way as the moſt ſucculent ſorts of Aloes.

[Browne ſays, that the ſecond ſpecies roots from the joints, and is very eaſily propagated in Jamaica; but thrives beſt in a warm rich ſoil.

PORTULACA. See *Atriplex*, *Cactus*, *Glinus*, *Montia*, *Sefuvium*, *Trianthema*.

   Craſſula portulacæ facie arboreſcens. *Dill. elth.* 120. *t.* 101. *f.* 120.

DESCRIPTION, &c.

1. This plant riſes with a ſtrong thick ſucculent ſtalk to the height of three feet, ſending out branches on every ſide, ſo as to form a kind of pyramid, the lower branches being extended to a great length, and the others diminiſhing gradually to the top; they are of a red or purpliſh colour and very ſucculent. The leaves are alſo ſucculent and roundiſh, very like thoſe of Purſlane, whence the gardeners call it the Purſlane Tree.

[Native of Africa. It was cultivated in Sherard's botanic garden at Eltham before the year 1732. In that year Dillenius's ſumptuous catalogue of that famous garden was publiſhed, and then this plant had been well known many years before, but had not flowered: "quæ (planta) licet ſatis vulgaris ſit et a "multis retro annis innotuerit, ejuſque plantæ ſatis "annoſæ paſſim obſerventur, non memini tamen flores "ejus vel a me, vel ab aliis adhuc obſervatos eſſe." Mr. Miller has it in the ſecond volume of his Dictionary, publiſhed in 1739.

I do not know that it has yet flowered in England, any more than in the Swediſh ſtoves. It flowered in Italy and Linnæus had the characters of the fructification from Turra.]

PROPAGATION AND CULTURE.

It is propagated with great facility by cuttings, planted during any of the ſummer months, and having been laid to dry for ſome days before. It muſt be placed in a warm glaſs caſe in winter, where it may enjoy the full ſun, and ſhould have very little water during that ſeaſon. In ſummer the plants ſhould be placed abroad in a ſheltered ſituation, and in warm weather ſhould be refreſhed with water twice a week; but the ſtalks being very ſucculent, too much wet is always hurtful to the plants.

Leaves briſtle-ſhaped oppoſite.

14. Potamogeton contortum. *Deſfont. atlant.* 150.

Stem filiform, leaves alternate ſubulate-filiform contorted.

DESCRIPTIONS, *&c.*

Theſe are perennial herbaceous plants, inhabitants of the water.—Leaves ſheathing; thoſe on the ſtem often alternate, the floral leaves frequently oppoſite. Flowers in ſpikes, terminating or axillary; the branchlets and ſpikes have often two ſpathes at the baſe [a].

1. The root conſiſts of long ſimple fibres. The ſtems are very long, round, leafy. Lower leaves ſubmerſed and linear; upper ones floating, oval-oblong, nerved, on long petioles. Stipules intrafoliaceous, linear, acute, almoſt equal to the petiole. Peduncles ſolitary, with a bracte at the baſe of the ſame form with the ſtipules, ſimple, thick, round. Spike ſimple, emerging from the water. Flowers browniſh-green [b]. Gærtner will have what Linneus calls naked ſeeds to be drupes.

Dr. Stokes remarks that the leaves of this ſpecies are opaque, whereas in the others they are pellucid: they alſo float wholly, like thoſe of Nymphæa, on the ſurface of the water [c]. The leaf-ſtalks are for the moſt part longer than the leaves [d]. The ſheaths are very large. Spikes cylindrical, two inches long, cloſe, ſlender [e]. Flowers numerous, (forty-five) ſeſſile, greeniſh or yellowiſh [f].

Native of Europe, in ſlow rivers, lakes, ponds and ditches: flowering in july and auguſt.

The floating leaves afford an agreeable ſhade to fiſh, and are the habitation and food of a moth named Phalæna potamogetonis. The roots are a favourite food of the ſwan [g].

Linneus remarks, that when it grows in water which is dried up in ſummer, it ſurpriſingly changes its appearance, growing upright and reſembling a ſmall Plantago [h]. According to Dr. Withering, in this caſe, the ſheaths of the peduncles and petioles are leſs than half the length of their reſpective ſtalks. The leaves are alternate, except the upper pair: the lower ones are lanceolate, on long petioles; the upper ones are oval, with ſhorter petioles. The ſtem is about four inches high. It is a ſmaller plant, and flowers a month or ſix weeks earlier than the common plant. Dr. Withering found it on boggy ground, on Birmingham-heath.

2. This reſembles the preceding, and perhaps is only a variety ariſing from place: about Berlin however it is conſtantly diſtinct. In rivers of Europe.

3. In the upper leaves this reſembles *P. natans* and *fluitans*, but it is only half the ſize, and diſtinguiſhed by its lower leaves being linear, and very like thoſe of Graſs.

Native of Germany, in ponds [i].

I have inſerted theſe two plants, though I can ſcarcely regard them as diſtinct ſpecies. Desfontaines obſerved the leaves to be ſometimes lanceolate and acute, in Barbary. Pollich remarks that the leaves under water have the petioles of a great length in rapid ſtreams. Our common broad-leaved Pondweed has the ſubmerſed leaves linear, and is therefore heterophyllous. Theſe differences therefore ſeem only to conſtitute varieties.

4. Stems very long, round, alternately branched, with leaves crowded about the top and branches. Leaves cordate-ovate, or rather ovate than cordate, at leaſt in the moſt common appearance of the plant; they are almoſt all uniform. Spikes erect, ſolitary, ſhort, brown. Petals bent in and converging, but diſtant at the baſe; they are of a dull purple, and from their ſituation, the air eaſily paſſes between them, to waſt the pollen to the ſtigma. The ſeeds are compreſſed and ſhining.

Every part of the plant, except the flower-ſtalks, is under water, ſo that it is only diſcovered by the ſpikes ſtanding a little above the ſurface in july and auguſt, and abounding in whitiſh pollen. It ſhould ſeem that the reſpiration of ſuch truly aquatic vegetables muſt be as different from the reſpiration of thoſe which inhale atmoſpheric air, as the breathing of fiſhes is from that of beaſts and birds. Accordingly the leaves are of a different texture, pellucid like oiled paper, as Haller remarks, very vaſcular, harſh and ribbed, but often very brittle; their ſurface, like that of aquatic animals, deſtitute of hair or down of any kind [k].

Linneus ſays, that the leaves in this and the other ſpecies are moſt uſually alternate, but at the forkings of the fruiting ſtalk oppoſite.

Native of Europe, Siberia, Barbary, in ditches, ponds, lakes and ſlow rivers.

Haller has made Loeſelius's plant a different ſpecies, n. 844.

5. This propagates itſelf by runners which throw out fibrous roots here and there into the mud, and ſend up round ſtems, naked and ſimple below, dichotomous above, and thickly clothed with numerous pairs of oppoſite ſeſſile ſpreading leaves, both rows of which often incline to one ſide. Each leaf is ribbed, waved and entire. According to Withering, they are linear-lanceolate, three-ribbed, with the edges very finely ſerrulated. Haller, Pollich and others ſay that the leaves are not ſerrate, and Dr. Smith has not found any ſerratures or prickles on their margin. Peduncles from between the diviſions of the ſtem, the uppermoſt terminating, till young branches are protruded beyond it, ſolitary, ſhort, round, recurved, bearing a ſhort ſpike, or rather a little head, of two or four flowers, well compared by Cluſius, and by Gerarde after him, to thoſe of *Aduxa*. Every part of the flower is pale green [l].

According to Mr. Abbot, one flower ariſes from the fork of the ſtem, ſitting on a ſhort fruit-ſtalk. Bauhin and Cluſius ſay that there are three or four flowers together, and this is confirmed by Desfontaines.

Native of Britain, Denmark, Flanders, France, Germany, Switzerland, Italy, Siberia and Barbary; in ditches, ponds and ſlow ſtreams; flowering in the early part of ſummer.

Dr. Goodenough remarks, that it varies in ſize according to the depth of the water.

6. Stems long, nearly ſimple, a little flexuoſe or zigzag, leafy, round. Leaves alternate, except where the flowers are ſituated, entire, a little waved, ribbed, running down into a ſhort foot-ſtalk, and accompanied by a long obtuſe folded intrafoliaceous ſtipule, longer than each joint of the ſtem. According to Withering, the leaves are beautifully green and pellucid, like thoſe of the *perfoliatum*, ſometimes eight inches long, and an inch and half broad. Flowers in a long denſe ſpike, on a round tumid ſtalk, which ſtands ſolitary in the axil of one of the oppoſite leaves, and is ſheathed at

[a] Juſſieu. [b] Smith. [c] Linn. lapp. & Haller. [d] Withering. [e] Haller. [f] Woodw. Neck. Withet. [g] Lin. ſuec. & Withering. [h] Fl. lapp. [i] Willdenow. [k] Smith, angl. & Engl. bot. [l] Id. Id.

the

the bottom by the ſtipule. Flowers dark green; the ſtigma often purpliſh [a]. Dr. Withering ſays the flowers are reddiſh.

There are two common varieties of this ſpecies; one with lanceolate leaves, tapering down very gradually to their inſertion, figured in Flora Danica, &c. the other with leaves perfectly ovate, and placed on a real foot-ſtalk, leſs perceptibly winged by the running down of the leaf; as figured in Engliſh Botany: theſe two plants however differ in no other reſpect, and may eaſily be traced one into the other.

It is frequent in ditches, ponds, lakes and ſlow-flowing rivers, chiefly on a clay ſoil, growing, like moſt others of the genus, all immerſed in the water, except the ſpike of flowers, which appears above the ſurface about midſummer, or a little after [b].

7. Stem angular. Leaves immerſed, blunt, commonly alternate. Peduncles emerging. Spike few-flowered. Flowers reddiſh, ſomewhat remote [c].

Stems branched, flatted. Leaves alternate, but at the forks of the ſtem oppoſite, ſeſſile, nearly linear, ſemitranſparent, very criſp. Spikes as long as the peduncles. Flowers white or reddiſh [d].

Stem reddiſh. Leaves rigid, the lower alternate, the upper oppoſite and heaped at the top of the ſtem. Spikes from ſix to eight-flowered. Peduncles from two to four inches long [e].

Stems numerous, of various lengths, dirty fleſh-coloured, ſomewhat tranſparent, flattened with a groove on each ſide. Sheaths ſhort, of the ſame colour as the ſtem, ſcarcely to be diſtinguiſhed. Leaves ſhining, three-ribbed, ſharply and finely ſerrate. Peduncles thickiſh, ſomewhat flattened. Petals greeniſh brown. Filaments ſcarcely to be diſtinguiſhed. Anthers white. Seeds naked, rather large, dirty green, flattened on each ſide, toothed externally at the baſe [f].

Native of Europe and Siberia, in ponds and ſlow rivers; flowering in june and july.

Ducks very readily eat not only the ſeeds but the leaves; the introduction of water-fowl therefore may probably prevent it from increaſing too much [g].

β. In this variety the upper leaves are oppoſite, whereas in the other they are commonly alternate [h].

8. This is not a variety of the preceding, but differs chiefly in having the leaves more in cluſters and quite entire [i].

Haller refers to ſynonyms, which we have given under *lucens*; and ſays that the waving edges make the leaves appear to be ſerrate, although they are not really ſo. In the Swiſs lakes the plant grows to the length of from ten to twenty fathoms, forming whole woods as it were in the middle of them.

Krocker ſays that the edges of the leaves are really ſerrate; the peduncles thick and reflex; the ſtipules long, wide, whitiſh; the ſpike eight-flowered and cylindrical.—Native of Europe.

9. Stem flexuoſe, alternately branched, very much compreſſed all the way up. Leaves pale green, generally alternate, but the uppermoſt often oppoſite, quite entire, all exactly linear, having a ſtrong central nerve, and two fine lateral ones on each ſide. Stipules intrafoliaceous, one to each leaf and wider, embracing the ſtem, flatted or depreſſed in angles; the lower ones generally acute and lacerated, the upper ones more obtuſe and entire. Peduncle ſhort, ſolitary, flatted, terminating till the ſtem grows above it. Flowers about four or ſix, diſtant in pairs. It has moſt affinity with *P. puſillum*, but is twice as large in all its parts, and eſſentially diſtinguiſhed by its compreſſed ſtem; neither do the leaves ſpread ſo immediately from the baſe as in that ſpecies [k].

Withering remarks, that the leaves are narrower than in the ſeventh ſpecies, and not waved; the ſpikes ſhorter than the peduncles; and the flowers greeniſh.

Ray ſays, that it has the leaves of *Triticum repens*, but ſhorter, with three nerves; a thin pellucid ſheath under each leaf; a ſhort ſpike of pale-green flowers.

Lightfoot remarks, that the leaves are four or five times longer than the ſtipules; and that the ſpike produces about ſix ſmall flowers.

Native of Europe, in ditches and ſlow ſtreams; flowering in june and july, when its ſmall ſpikes of about four or more browniſh-green flowers emerge from the water [l].

10. Stem ſlender, flexuoſe, very much branched. Leaves ſpreading, approximating, bluntiſh, ſcarcely ſerrulate. Stipules rolled up and tubular; thence, at leaſt the lower ones, narrower than the leaves. Spikes ovate, few-flowered, cloſe, ſolitary; the primary one, from the forking of the ſtem. Peduncles the length of the ſpikes. The Pondweed figured in Flora Danica, t. 222. ſeems to be a different ſpecies [m].

Native of Europe, in ditches and ſlow ſtreams. Near Deptford. Binſey-common. Ditches by the road ſide going to Port-meadow, Oxford. River Skern, near Darlington. It flowers in july.

11. The root of this, as well as of the preceding, has all the appearance of being perennial, though Linnæus marks it as annual; and ſeveral fibres are thrown out from the lower part of the ſtem, which is very ſlender, ſtriated, and alternately branched above. Leaves very narrow, moſtly alternate, but oppoſite under every peduncle, not ſheathing the ſtem, their margin perfectly ſmooth and entire. Stipules membranous, lanceolate, inſerted above each leaf and much broader than it, embracing. Peduncles axillary, ſolitary, frequently terminating till the ſtem ſhoots beyond them, ſhorter than the leaves, longer than the ſpike; which is ovate, ſmall, cloſe, bearing three or four greeniſh flowers [n].

The whole plant is extremely ſlender, and the ſtem much branched. Leaves pointed, ſpreading extremely at the baſe, ſometimes almoſt bent back. Stipules ſhort, but broader than the leaves. Spike ſhort, Flowers pedicelled [o].

Leaves rather longer than the internodes. Spikes nearly globular, with about three flowers in each [p].

Native of Europe, in ditches and ponds, eſpecially in a clayey ſoil; flowering in july.

12. Root originating from a tuberous lump, then creeping horizontally, ſlender, much branched, as is alſo the ſtem, which floats under water, extending often two or three feet; it is round, with alternate approximating branches. The leaves, though extremely narrow and pointed, are flat and grow alternately, ſpreading in two directions, on the ſmall branches, having long ſheathing baſes. Stipule growing to the leaf, with a membranaceous margin, and a bifid acute top. The flowers only riſe above the water in june or july, in a ſimple ſpike, but cluſtered two or three together irregularly, often on very long peduncles, the lower ones very remote. Petals kidney-ſhaped, of a dull olive colour. Anthers yellow, very diſtinctly two-lobed. Stigmas obtuſe, entire [q].

According to Withering, the petals are whitiſh. Mr. Stackhouſe ſays, there are five or ſix flowers on each peduncle. Mr. Ray, that the upper branchlets end in looſe ſpikes compoſed of three or four flowers in a ſort of whorl.

Native of Europe, in ponds, and not unfrequently in rivers, in which, if the ſtream be rapid, it rarely flowers.

β. Leaves growing from the ſheaths, which are ſlightly forked at the extremity, as in *P. pectinatum*. In ſtagnant ſalt water ditches the whole plant is ſhorter; the branches and leaves cloſer and more frequent. In running water, ſalt or freſh, it grows to a vaſt length, and the branches and leaves are farther aſunder, but in both caſes preſerve their parallelism. Spike long, with ſeſſile flowers, growing moſtly in interrupted whorls: t. 186, in Flora Danica more exactly reſembles our freſh than ſalt water plants, though quoted in *Syſt. veget.* for *P. marinum*. In water that is quite freſh it becomes *P. pectinatum*, according to the obſervation of Mr. Crowe [r]. Dr. Smith does not perceive differential marks in the marine plant ſufficient

[a] Engl. bot. [b] Idem. [c] Smith, angl. [d] Withering. [e] Relhan. [f] Curtis. [g] Idem. [h] Smith. [i] Willdenow. [k] Smith. [l] Smith. [m] Idem. [n] Idem. [o] Woodward. [p] Withering. [q] Engl. bot. & Smith, angl. [r] Woodward in Withering.

even to conſtitute it a variety of that which grows in freſh water.

13. This is diſtinguiſhed by its oppoſite briſtle-ſhaped leaves.—Native of Europe in ditches. Mr. Hudſon found it in peaty ditches in Lancaſhire. On his authority it reſts entirely as an Engliſh plant.

Dr. Smith has not ſeen the plant either in the Linnean herbarium or elſewhere. It flowers in july and auguſt [a].

14. Found by Desfontaines in the rivulets of Caſſa in Barbary [b].

Claſſ. 12. 5. Icoſandria Polygynia.

Nat. order of *Senticoſæ*. *Roſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, flatiſh, ten-cleft: the alternate ſegments ſmaller reflex.

COR. *Petals* five, roundiſh, ſpreading, inſerted by their claws into the calyx.

STAM. *Filaments* twenty, awl-ſhaped, ſhorter than the corolla, inſerted into the calyx. *Anthers* elongate-lunulate.

PIST. *Germs* numerous, very ſmall, collected into a head. *Styles* filiform, the length of the ſtamens, inſerted into the ſide of the germ. *Stigmas* obtuſe.

PER. none. Common receptacle of the ſeeds roundiſh, juiceleſs, very ſmall, permanent, covered with ſeeds, incloſed within the calyx.

SEEDS numerous, acuminate-wrinkled. *G.*

OBS. *If a fifth part of the number be taken away in all parts of the fructification* Potentilla *gives* Tormentilla: *ſince they differ therefore only in number, the two genera might be combined.*

ESSENTIAL CHARACTER.

Cal. ten-cleft. *Pet.* five. *Seeds* roundiſh, naked, faſtened to a ſmall juiceleſs receptacle.

SPECIES.

* *With pinnate leaves.*

DESCRIPTIONS, *&c.*

Theſe are moſtly perennial herbaceous plants, the firſt is ſhrubby, and one or two ſpecies are ſaid to be annual. The leaves are unequally pinnate in ſome, (Pentaphylloides, *Tourn.*) digitate in others, (Quinquefolium, *Tournef.*) and in a third ſet ternate, as in Fragaria; hence Linneus's three ſubordinate diviſions. Stipules like wings faſtened to the bottom of the petiole. Flowers commonly in terminating corymbs *.

Tournefort and others ſeparated this genus too much. Haller has thruſt too many genera into it. Linneus had no objection to *Termentilla* being joined to *Potentilla*: but Haller has inſerted *Frogaria*, *Potentilla*, *Tormentilla*, *Sibbaldia*, *Comarum*, and called the whole *Fragaria*.

*1. The whole plant is ſet with fine ſilvery hairs. Stems erect, clothed with a brown bark which cracks longitudinally, branching very much, about three feet (or in gardens four feet) high, frequently reddiſh. Leaves alternate, covering the branches, petioled, quinate-pinnate, or conſiſting of five rarely ſeven oblong leaflets, ſomewhat rolled back, quite entire, hairy underneath, the upper ones ternate. Dr. Withering ſays, the leaves can hardly be called pinnate, conſiſting of two pairs ſet croſs-wiſe, riſing from the ſame point, with a terminating one divided down to the baſe into three open ſegments; and that the leaflets are linear-lanceolate, turned back at the edges, dark green above, pale underneath. Loureiro affirms that they are truly pinnate, though repreſented as digitate in Amman's figure. Stipules embracing. Flowers terminating, ſolitary, peduncled, of a bright yellow or golden colour and very ornamental; petals roundiſh or obcordate. The five outer leaves of the calyx are oval, ſpreading and remarkably large †.

Native of Oeland, England, Siberia, China; between the rivers Delaware and New York in North

* Juſſieu. † Smith and Withering.

America.

America. In England this ſhrub was firſt obſerved by Johnſon of Brignal near Greta-bridge in Yorkſhire, on the ſouth bank of the Tees below Thorp, and below Eggleſton Abbey in Yorkſhire. He ſhowed it to Mr. Ray, and communicated the ample deſcription which is given in his Hiſtory of plants. Mr. Lawſon afterwards obſerved thouſands of theſe plants by Mickle Force, in Teeſdale. Mr. Robſon, of Darlington, informs us, that it ſtill grows about the river Tees plentifully. It flowers with us in June and July.

The beautiful appearance of its numerous flowers has gained this ſhrub admittance into gardens. Beſoms are made of it. Kine, horſes, ſheep and goats are ſaid to eat it, and ſwine to refuſe it [q].

2. Root branched, outwardly dark brown or whitiſh, furniſhed with ſmall fibres, and penetrating deep. Stems or rather runners extending to a conſiderable length, round, jointed, reddiſh, downy, creeping. Leaves ſilvery-white underneath, petioled: leaflets ſeſſile, oppoſite, oval, gaſh-ſerrate, blunt, the lower ones gradually ſmaller: the root-leaves on longer petioles and procumbent. Petioles villoſe, flat on the upper ſide, forming a ſheath at the baſe, which is hollow, membranous, tender, downy, running down each ſide of the petiole. Sheaths of the ſtem or rather ſtipules of the runners ſolitary at the joints, bifid and often multifid at top, bearing an oblong indented ſmall leaf. Peduncles axillary, ſolitary, round, villoſe, upright. Calyx ſilky, the five inner ſegments entire, ſharpiſh, yellowiſh at the baſe; the five outer blunt iſh and jagged. Petals yellow, obtuſe, twice the length of the calyx. Receptacle hairy. Germs ovate, obtuſe, white, ſurrounded by theſe hairs: ſtyles yellowiſh, ſhorter than the ſtamens: ſtigmas truncate.

Few plants render themſelves more conſpicuous by the whiteneſs of their leaves than this, indeed its old name Argentina was derived from this circumſtance; it muſt be remarked however that in this particular it is ſubject to much variation, the leaves being ſometimes ſilvery on both ſides, and ſometimes entirely green, but it is moſt commonly found with the upper ſide of the leaves green, and the under ſide ſilvery; the more clayey the ſoil, the whiter the leaves are generally found to be.

It is a plant which thrives moſt in moiſt ſituations, eſpecially in clay where the water is apt to ſtagnate, and is common by way ſides; flowering from june to ſeptember [r.] Mr. Miller ſays it is a ſure mark of the ſterility of the ſoil.

[Ray informs us, that about Settle in Yorkſhire they call the roots *Moors*, and that during the winter the boys dig them up and eat them: he adds, that he was a witneſs to ſwine devouring them greedily, and that an apothecary of that neighbourhood aſſured him that they had a ſweet taſte, like Parſneps.

Theſe roots are frequently eaten by the common people in Scotland, either roaſted or boiled. In the iſlands of Tirey and Col they are much eſteemed, as anſwering in ſome meaſure the purpoſes of bread; they have been known to ſupport the inhabitants for months together during a ſcarcity of other proviſions. In their barren and impoveriſhed ſoils, and in ſeaſons wherein their crops ſucceed the worſt, the roots of the Moor-graſs never fail to afford a ſeaſonable relief to them [s].

The leaves are mildly aſtringent; dried and powdered they have been given with ſucceſs in agues; the uſual doſe is a table-ſpoonful of the powder, every three hours, between the fits. Kine, horſes, goats and ſwine are ſaid to eat it; and ſheep to refuſe it [t].

It ſhould ſeem by the names *Anſerina*, *Gooſe-graſs*, and *Gooſe Tanſey*, that geeſe are fond of it. The leaves reſemble thoſe of Tanſey very much; hence it is alſo called *Wild Tanſey*.

3. The habit of the leaves is that of the preceding, although they are very ſmall: but it has the ſtem and fructifications of the *verna*. The root is clothed with black ſcales which are the remains of leaves. The leaves conſiſt of about thirteen ovate ſilky leaflets, which are pectinate-pinnatifid. Peduncles hairy. Stems twice or thrice the length of the leaves, having no runners, and not creeping, furniſhed in the middle with a ſingle ſmaller and more divaricating leaf, round, with a few yellow alternate peduncled flowers at top.

Native of Siberia [u]. Introduced in 1780 by Peter Simon Pallas, M. D. [x]

4. The habit ſhows much affinity with *P. argentea*. The leaves conſiſt of ſeven leaflets. The ſegments are linear or lanceolate, five or at moſt ſeven, alternate except in the odd leaflet where they are oppoſite, gaping from each other or remote at the tip, tomentoſe underneath [y].

Gmelin and Pallas refer n. 116 of Ammann and the ſynonym from Buxbaum to *P. biſurca*. Pallas ſays, that Linneus's deſcription given above is a variety of *P. ſericea*.

Native of Siberia—Linneus ſays of Tartary alſo, Cappadocia and Switzerland; but he has probably mixed two plants together. Cultivated in 1759, by Mr. Miller [z].

5. This has the appearance of *Fragaria ſterilis*. Root ſomewhat tuberous. Leaves ſilky on hairy petioles, with three, five or ſeven leaflets, which are ovate, oppoſite, ſerrate, leſſening as they approach the baſe. Runners decumbent [a].

Willich refers Haller's name to *P. ſtipularis* [b].

Native of Siberia. Introduced in 1773, by Chevalier Murray [c].

6. Whole plant hairy. Stem forked above. Leaves, ſerratures, and ſegments of the calyx tipped with ſcarlet or purple [d].

Stem almoſt a foot high, branched, leafy, ſtriated. Leaflets ſubovate, blunt, gaſh-ſerrate, veined, hairy but not hoary, five or ſeven in the root-leaves and lower ſtem-leaves, three only in the upper ones. Radical ſtipules linear, acute; roundiſh-rhombed to the ſtem-leaves. Peduncles ſubpanicled, one-flowered, villoſe. Calyx villoſe at the baſe. Petals obcordate, white. Styles reddiſh. Seeds not wrinkled, but of an even ſurface; hence perhaps it ſhould be referred to *Fragaria*, to which it is allied in appearance [e].

Native of ſeveral parts of Europe and Siberia, on ſhady alpine rocks. With us it has occurred only in Wales, on the ſides of Craig Wreidhin mountain in Montgomeryſhire, where it was found by Lhwd [f].

7. Root fuſiform, little branched. Stem almoſt upright, round, tomentoſe, branched, a foot high, dichotomous, at the extremities very ſlender, almoſt filiform, leafy. Lower leaves pinnate, gaſh-ſerrate, with two, three or four pairs of leaflets, with the end one trifid or bifid, wedge-form, ſmooth, on ſhort petioles, which are alternate, winged and placed on ſmall ſtipules; the number and ſize of the leaflets are ſucceſſively diminiſhed, ſo that at the extremities ſegments remain which are very ſhort, ſolitary, petioled, bifid or more frequently trifid. Flowers come out ſingly from the axils alternately almoſt over the whole ſtem, on peduncles half an inch long, very ſlender, villoſe, reflexed when the flower goes off. Calyx whitiſh green, ſomewhat hirſute, with the ſegments almoſt equal. Petals ſmall, brimſtone coloured, equal to the calyx [g].

Native of Siberia and Sileſia. Introduced in 1773, by John Earl of Bute [h].

8. Found by Tournefort in Armenia, among rocks. Cultivated in 1758, by Mr. Miller. It flowers from june to auguſt [i].

9. This has the habit of *P. recta*. Root-leaves pinnate; leaflets oblong, blunt iſh, ſerrate-toothed, marked with lines, ſoft, villoſe; the three outer connate and larger; the inner ſmaller and alternate: ſtem-leaves ſubdigitate, in ſevens, as in *P. recta*, but pinnatifid. Petals ſcarcely larger than the calyx [k].

Native of North America. Introduced in 1773, by John Earl of Bute. It flowers from june to auguſt [l].

[q] Withering. [r] Curtis. [s] Lightfoot. [t] Withering.

[u] Linn. ſpec. [x] Hort. kew. [y] Linn. ſpec. [z] Hort. kew. [a] Linn. ſpec. [b] Reichard. [c] Hort. kew. [d] Withering. [e] Smith. angl. [f] Ray, ſyn. [g] Krocker. [h] Hort. kew. [i] Idem. [k] Linn. mant. [l] Hort. kew.

10. Root ſmall, white within, covered on the outſide with brown ſcales. Stem a foot or more in length, procumbent, dichotomous, leafy, round, having a few hairs on it: branches oppoſite. Leaves alternate except the uppermoſt which are conjugate, two inches in length, and near one inch in breadth, on long petioles: pairs of leaflets four or five, with the odd one more cloven, all oblong-ovate or lanceolate, gaſh-ſerrate, ſeſſile, white-tomentoſe on the back, near half an inch long, and three lines wide. Rachis pubeſcent, grooved above. Petioles ſlightly hairy, placed on embracing, ovate, acute ſtipules, ciliate at the edge. Peduncles from the forkings and tops of the branches, alternate, ſolitary, round, pubeſcent, four lines in length, erect but hanging down after the flower is gone off. Flowers little more than three lines in diameter. Calyx ſlightly pubeſcent: ſegments ovate, unequal, green not white. Petals yellow, obcordate, blunt, much ſmaller than the ſegments of the calyx. Receptacle pappoſe [m].

Native of Germany, Auſtria and Siberia. Introduced in 1773, by Chevalier Murray. It flowers in july [n].

11. Stem about a foot high, rigid, covered with a pile rather than hairs, reddiſh, at top corymbed, or dividing into ſeveral peduncles forming a ſort of umbel. Leaves large, having each five or ſeven oblong villoſe leaflets, frequently of a ruſſet colour, with ten or twelve blunt teeth; they are ſtiffer, longer and wider than in *P. hirta*, and when old are almoſt naked: the lower ones are petioled, the upper ones ſeſſile, finally becoming linear and ſtipular. The flowers are abundant on the top of the ſtem, erect on ſolitary peduncles, altogether making the ſtem panicled. Calyx tomentoſe, whitiſh, with almoſt equal ſegments. Petals large, emarginate, of a golden colour. Receptacle pappoſe [o].

Native of Germany and the South of Europe. Cultivated in 1648, in the botanic garden at Oxford. It flowers in june and july [p].

12. Stems many, woolly, round, hard, half erect, from a ſpan to a foot or more in height. Leaves alternate, petioled, the upper ſide green, the lower covered with ſnow-white cottony down, as are the calyx and upper part of the ſtem, which laſt is dichotomous, and aſſumes the form of a corymb at top. The lower petioles are long, but gradually ſhorten upwards. The floral leaves have one or three linear entire ſegments. The flowers are numerous. The calyx downy, as long as the corolla: the petals ſmall, bright yellow or golden coloured, and ſoon ſhedding. The flowers appear in ſucceſſion from june to autumn. Seeds ſmoothiſh. No other Britiſh Potentilla can be confounded with this. Its form and habit much reſemble the *Tormentilla*, except in being far more woody. The pure whiteneſs of the leaves, like that of the white Poplar, renders this plant conſpicuous whenever it is diſturbed by wind or any other accident [q].

Native of Europe. It was reckoned by Ray among our rarer plants, but is found in many parts of England on a gravelly ſoil. It is ſaid to indicate clay under the ſurface [r].

In Cambridgeſhire it grows among furze, near Hilderſham, Gamlingay and White-wood. In Oxfordſhire on Henley-park Hill. In Bedfordſhire at Ampthill, Aſpley, and Rowney Warren. Near Harefield in Middleſex. On Blackheath, Kent. Holt Caſtle in Worceſterſhire. Among furze on the heaths and on the walls in Purbeck, Dorſetſhire. About Harrowgate in Yorkſhire it is plentiful. Near Snenton in Nottinghamſhire In the den of Bethaick near Perth in Scotland. It flowers from june to ſeptember.

13. This is a middle plant between *P. argentea* and *norvegica*, whence its trivial name; it would indeed be the latter, if the root were not perennial, and the leaves next the foot quinate. But the lower leaves are alternate, the upper oppoſite: leaflets obovate, gaſh-ſerrate, not tomentoſe, with nine ſerratures: the ſtem-leaves are ternate, oppoſite to the panicle [s].

Monſ. Villars ſays that it approaches nearer to the *rectà* than any other, but that the ſpecies is well marked. The reddiſh villoſe ſtems a foot high, are much inclined, and branch out from the very bottom: the peduncles then are ſtraight and inclined, ſome ſimple, others forked. The leaves at bottom are in ſevens; they are oblong, villoſe, unequal, with ſeven or nine deep indentations: the ſtem-leaves are almoſt oppoſite, in threes, ſpringing between two large wide ſtipules: the uppermoſt are ſimple or trifid, and confounded with their ſtipules. Petals yellow, middle-ſized, emarginate. The diviſions of the calyx are very villoſe; and the receptacle is a little ſo.—Haller has given Linnæus's *opaca* as a ſynonym, and ſays that his deſcription does not much differ from it; the *opaca* however has no farther ſimilitude to this ſpecies than that of the genus. The *opaca* has the ſame relation to *verna*, that *intermedia* has to *rectà*, but it is not ſtraight, and the branches are filiform.

Native of Switzerland and Dauphiné.

14. Root-leaves five or ſeven; ſtem-leaves five, all alternate, ſublinear, with three or five teeth. Stem, peduncles and calyxes very hairy [t].

Monſ. Villars gives two ſpecies much reſembling each other, *hirta* and *piloſa*; both have ſtraight ſtiff ſtems, long hairs and deep indentations on the leaves. This is a foot high, and has many ſtems; it is not viſcid; it is rougher, ſtraighter and harder than the *piloſa*. It has the port of *P. argentea*, but is not at all white or ſilvery, only duſky and rough with long diſtinct hairs. *P. piloſa* is ſmaller than the *hirta*. Stems villoſe, about half a foot high; having at top three or four yellow, middle-ſized flowers, with emarginate petals. Leaves quinate, villoſe, deeply cut at the end, unequal, ſo that the lower or lateral ones are ſcarcely half the length of the middle ones, they have all long, weak, diſtinct, and very apparent hairs. The whole plant is a little viſcid. The *heptaphylla* of Miller, *n.* 9. ſeems to be the *hirta*.

Native of the South of France, the Pyrenees and Sileſia. Cultivated in 1725 in the botanic garden at Cheliſea. It flowers from may to ſeptember [u].

15. Stem aſcending, filiform, even, divided at the tip. Stipules embracing, ſolitary, emarginate. Leaflets eight or nine, linear-lanceolate, ſubſerrate, ſmooth, hanging from the notch of the ſtipule without any petiole.—Native of Siberia [v].

16. Stems ſhort, branched from the bottom, decumbent, round, ſoft, tomentoſe, reddiſh, forming a tuft. Leaflets ſeſſile, obovate, ſoft, tomentoſe, hoary: petioles ſheathing, channelled above, villoſe, an inch and half in length. Stipules ſoft, tomentoſe. Floral leaves ſeſſile, trifid and jagged. Flowers in a ſort of panicle at the ends of the branches. Peduncles one-flowered, leſs than half an inch in length. Petals yellow, blunt [x].

Villars deſcribes his *opaca* as having the port of the *verna*, but larger in all its parts. Leaves wider, of an aſh-coloured or ruſſet green on both ſides; like thoſe of the *ſubacaulis* lanuginous, blunt, with regular rounded indentations. Corolla ſmall, ſomewhat notched, a little longer than the calyx, pale yellow without any deeper ſtain. Segments of the calyx blunt. This, with the ſhort cloſe pile that covers the plant, independant of the colour, ſize, &c. diſtinguiſhes it at firſt ſight from *P. verna*.

Native of Germany, and ſome parts of the South of Europe.

17. Stems from three to ſix or ſeven inches high, nearly erect, branched, leafy, hairy. Leaves thin and almoſt membranous, of a lighter green than in *P. verna*, with foot-ſtalks more than twice as long: leaflets five, a little ſhining, ſomewhat hairy, paler beneath, and deeply ſerrate towards the top: root-leaves on very long petioles, with blunt leaflets; ſtem-leaves ſubſeſſile; uppermoſt moſtly oppoſite. Stipules lanceolate, entire. Peduncles axillary and terminating,

[x] Pollich.

ſolitary, very long, one-flowered, hairy, erect. Calyx hairy, its ſegments all nearly equal in length, but alternately narrower. Petals obcordate, of a full yellow and almoſt orange colour. Seeds longitudinally wrinkled, which Gærtner conſiders as a diſtinguiſhing character of this genus [a].

Native of the mountains of Scotland, Denmark, Switzerland, Auſtria, Sileſia and Dauphiné. It was firſt introduced as a Britiſh plant in Dr. Withering's new edition of his Arrangement, on the ſuppoſition of its being *Pentaphyllum parvum hirſutum* of Ray's Synopſis, referred by Hudſon to *P. opaca* of Linneus. But Mr. Curtis is moſt probably right in referring Ray's plant to the *verna*. The real *aurea* was gathered in 1793 on Ben Lawers and other mountains of Breadalbane, by Mr. John Mackay. It flowers in july [b]. It was cultivated by Mr. Miller in 1739; not being then known to be a native of England.

Crantz, Allioni and Villars have a ſpecies which they name *rubens*, from the redneſs of the ſtalks. Reichard refers Crantz's plant, with a mark of doubt, to Linneus's *opaca*: it has the lower leaves quinate, the upper ternate, and deep-yellow flowers without any ſpots. Allioni has deſcribed it at length, and refers to Villars; who ſays that it may be the *rubens* of Crantz; that the ſtems, leaves and flowers exactly hold a middle place between *P. aurea* and *intermedia*; that it has the ſize of the former, with fewer flowers, rougher blunt leaves, and a ſmaller corolla of a deep yellow colour; but without a golden ſtripe at the baſe of each petal, which he and Crantz aſſign to the *aurea*. Our *aurea* has it not, and therefore probably is the ſame with the *rubens* of theſe authors; if the *rubens* be really different from the *aurea*.

Monſ. Villars has another ſpecies, which he names *inclinata*, and figures in his forty-fifth plate. The whole plant is hairy. The ſtem is very diſtinct and riſing, naked in part, bifid at top, where there are two ſmall ternate leaves. The lower leaves have five or ſix oblong leaflets, ſomewhat aſh-coloured, with blunt teeth on the edge; the ſtem-leaves are ternate and oblong. Petals yellow, the length of the calyx, truncate and not cordate.

18. The whole plant is beſet with ſoft ſhining ſilky hairs. Stems almoſt proſtrate, branched, leafy, ſpreading very wide in a circular direction among graſs. As the ſeaſon advances they turn red, as well as the leaves; which colour, intermixed with the bright yellow of the flowers, makes a ſtriking contraſt. Leaves rigid, ſomewhat coriaceous, ſmoothiſh, marked with lines, ciliate along the edge and keel: root leaves on longer petioles, quinate, with the leaflets wedge-ſhaped and ſomewhat retuſe; ſtem-leaves ternate, trifid, ſubſeſſile; upper ones ſimple and often entire. Stipules in pairs, lanceolate, embracing. Peduncles ſubterminating, (or terminating and axillary) one-flowered, long, ſlender, upright. Calyx tomentoſe and hairy, with the ſegments not very unequal, half as long as the corolla. Petals emarginate or obcordate, of a golden colour. Seeds leſs wrinkled than in the preceding [c].

Native of moſt parts of Europe, in dry elevated paſtures.

Thomas Williſell brought it to Ray from Kippax, near Pontefract in Yorkſhire; the Rev. Mr. Wood has ſince found it there. It has occurred in ſeveral other places of Yorkſhire and Lancaſhire, as Preſton, Giggleſwick, near Carr End Wenſleydale, &c. Sir Thomas Gery Cullum, Bart. obſerved it many years ſince near Bury, in Suffolk. It grows alſo on Gogmagoghhills near Cambridge. Mr. Pennant found it in Gloggaeth, Caernarvonſhire. In the King's Park, Edinburgh, near Arthur's ſeat, by Dr. Hope; and on Braid-hills and Craig Lochart, by Mr. Brown; and in ſeveral other parts of Scotland.

Haller obſerves, that it is a very variable ſpecies, and approaches ſo nearly to many others, that its characters and ſynonyms are ſcarcely to be made out [d].

Villars has three ſpecies, which he allows may poſſibly be varieties of the verna:

1. P. ſerotina; the leaves of which are a little larger and more cut; the ſtems longer; the flowers yellow without any ſtripe at the claw.

2. P. filiformis. Stems proſtrate, red, villoſe; leaflets five or ſeven, oblong, widening at the end, unequal, ſerrate; petals obcordate, deep yellow, a little larger than the calyx.

3. P. rotundifolia. Leaves ſmooth, wide, as are alſo the petals, inſomuch that they are often concealed one under the other. The leaflets have only four or five diviſions, which are ſmooth and rounded; whereas the ſecond has from nine to eleven diviſions of oblong leaflets, villoſe or rough-haired.

Villars has alſo another ſpecies, which he names *frigida*. It is a ſmall plant, with the ſtems creeping. The leaves reſemble thoſe of the *verna*, but they are ternate, villoſe, with ſharp deep indentures; the petals are narrow, rounded at the end; the diviſions of the calyx are large in proportion to the plant, they are equal, blunt, and nearly as long as the petals. The whole plant becomes red in autumn.

19. The ſeeds of this were received by Jacquin from Aſtracan. The firſt year they produced only radical leaves, but in the ſucceeding ones ſeveral ſtems, which were annual, aſcendant, round, ſomewhat villoſe, and about a foot high, ſpreading into panicled peduncles: the alternate and loweſt radical and cauline leaves are quinate, footſtalked, rather hirſute, and at their origin are auriculated on each ſide by a lanceolate ſtipule: the leaflets are oblong, obtuſe, ſeſſile, and inciſo-ſerrated: the remaining cauline ones and thoſe of the branches are ternate, with unequal and incided leaflets: the higheſt towards the peduncles are oppoſite, ſeſſile, and trilobate; or rather theſe are trilobate ſtipules without leaves. The peduncles are one-flowered, and rather ſhort: the calyxes hirſute: the petals yellow: the anthers deep yellow or luteous.

20. This has the habit of *Fragaria*. Root-leaves quinate: leaflets obovate, acutely ſerrate, pubeſcent above, villoſe and ſilky-white underneath; the petioles very hirſute with white hairs. Stem a finger's length, branched, with few leaves on it. Corolla yellow. It reſembles *P. verna*, but the leaves are very hairy, finely ſerrate, roundiſh; and the ſtem is very hirſute.

Native of Canada [e].

21. Stems branched. Root-leaves on long petioles: leaflets lanceolate, bluntiſh, entire except towards the end, where there are five or ſeven ſerratures; they are ſlightly downy above, paler and more downy underneath, with the veins and edges white with a ſilky down. The petioles are alſo downy. Peduncles very long, ſlender, downy, one-flowered. Segments of the calyx acuminate, ſilky. Petals white, obcordate, as long as the calyx. Receptacle villoſe with long, cloſe briſtles. Seeds obſcurely wrinkled [f].

Native of the South of France, Germany, Switzerland, Auſtria, Carniola, Hungary. According to Hudſon, it was found in Wales by Mr. Haviland. Dr. Smith ſays, that he knows of no other authority.

22. The procumbent ſtem riſes ſometimes to three or four inches in height, bearing ſeveral white detached flowers, from the middle of which ſpring the hairs of the receptacles. The leaves are on long petioles; thoſe that come out in ſummer continue on all the winter, and accompany the ſtem during the year following. The whole plant becomes red with age. Each leaflet is villoſe, entire, oval, rounded, with three or four pointed, approximating indentures at the top [g].]

The leaves are on foot-ſtalks which ariſe from the root, and are very long; the leaflets are oblong, a little ſerrate at their ends, very hoary and ſilky on their under ſides, but green on their upper. Flowers on long ſlender peduncles, which ariſe immediately from the root; they are white and appear in may, but are ſeldom ſucceeded by ſeeds in England.

Native of Auſtria, [Switzerland, Sileſia, Dauphiné, Piedmont. Cultivated by Mr. Miller in 1759 [h].

23. This, according to Jacquin, is an elegant ſpecies,

growing

growing among the clefts of the Alpine rocks, the ſtems are numerous, and are commonly roughened by the remains of the loſt leaves: the principal ſtems are decumbent, the others upright: the flowering ſtems riſe on the ſides of the terminal leaves; and are ſimple, erect, pubeſcent, purple, annual, two or three inches high, and bear but few flowers: the leaves are of a pale green. The flowers are ſubcorymboſe, pedunculated, inodorous, and the calyx is in ſome hirſute and purple: the petals white and obtuſe: the filaments in ſome white; in others red. Jacquin thinks it truly diſtinct from the P. cauleſcens of Linneus [i].

Native of Auſtria. Allioni does not think it diſtinct from the *cauleſcens* of Linneus.

24. This ſpecies is very ſmall; the ſtems are only an inch or two in height, ſometimes upright, ſometimes decumbent, bearing but one flower, ſeldom two. Leaves ſmall and ſilvery, three or four rarely five together; they are ſhort, quite white, a little notched, with two or three ſharp teeth at the end. Corolla white, open, with the petals a little longer than the calyx, entire, narrow at the claw, widening ſuddenly, as in moſt of the *Arenarias*, and then oval. The flower is frequently reflex. Receptacle lanuginoſe [k].

Turre remarks that the leaves are ternate. Linneus ſays, that he has a ſpecimen or two with the lower leaves only quinate, and that the root-leaves are to be determined by culture [l].

Villars informs us, that on Mont Bovinant it is ternate, and at Colet in the way to Charmanſon conſtantly quinate, although the plants are not larger or in any wiſe different from the others.

Native of Monte Baldo, Dauphiné, Auſtria.

25. There are a few ternate leaves on the ſtem. Flowers dichotomous, corymbed, cluſtered. Petals white, ſhorter than the calyx [m].

Villars remarks that this ſpecies may eaſily be confounded with *cauleſcens* and *alba*: but *cauleſcens* is partly decumbent, *alba* is quite ſo, and this not at all. *Alba* has narrow leaves, in *cauleſcens* they are a little wider, and in this ſtill more ſo. The upright villoſe ſtem riſes to the height of ſix or eight inches, and branches at top, where it has ten or twelve flowers very cloſe together. The leaves in ſome degree reſemble thoſe of the Lupin, and are in ſevens; the leaflets are villoſe, duſky, rounded, and ſlightly toothed at the end; they are wide enough to touch one another, and even to conceal their margins. Flowers in tufts: petals white, narrow, diſtinct, oblong, little emarginate, almoſt always approaching to the piſtils, which are villoſe and lanuginoſe.

According to Allioni, the root is thick, red, tough, and divided. This throws out a great number of leaves on long petioles, and many ſtems that are almoſt upright or a little reclining. The leaves proceed from a wide ſtipule, and the petioles are hirſute: leaflets firm, ſilky-hoary, veined and nerved underneath, five, ſix or ſeven. Stems almoſt naked, with flowers in a corymb on the branches. Stem-leaves quinate, on ſhorter-hooked ſtipules. Leaves at the origin of the branches ternate. Petals very pale ſulphur or white. The whole plant is ſilky-hoary, with the ſtems and petioles evidently ſubhirſute.

Native of the mountains of Piedmont and Dauphiné.

26. Root fuſiform, with few fibres, penetrating deep, the ſize of the little finger, or even of the thumb when old, outwardly of a dark cheſtnut colour. Stems round, ſmooth, proſtrate, creeping, leafy. Leaves petioled, erect, quinate, (ſometimes ſeptenate, ſometimes ternate;) leaflets obovate-cuneate, hairy, unequal in ſize, ending in purpliſh points. The petioles come out in pairs from the joints of the ſtem at conſiderable diſtances. Stipules in pairs, compoſed of three ovate or ovate-lanceolate leaflets. Peduncles ſolitary, nearly upright, longer than the leaves, one-flowered. Calyx hairy. Petals of a golden colour [n].

Native of Europe, common in meadows, and by way ſides; flowering from june to ſeptember.

[i] Jacquin. [k] Villars. [l] Syſt. veg. [m] Linn. ſpec. [n] Curtis, Smith.

Tormentilla reptans has been thought by ſome a variety of this, but they are very different; this ſtriking root at every joint, that trailing, but never ſtriking root from the ſtem [o].

This plant is the *Pentaphyllum* of the London Pharmacopœia. The roots have a bitteriſh ſtyptic taſte. They were uſed by Hippocrates and Dioſcorides, and by the former particularly recommended for the cure of intermittents. Ray tells us that the peaſantry ſtill employ them with this intention. The medicinal quality is confined to the red cortical part of the root, and depends merely upon its aſtringent effects; it has therefore been chiefly preſcribed internally in diarrhœas and other fluxes, and externally in gargles for looſe teeth and ſpongy gums, and in aſtringent lotions: but its efficacy being much inferior to many other plants of this claſs, Cinquefoil is now rarely uſed. In large doſes however, it may be found no bad ſubſtitute for ſome of the other aſtringents [p].

The roots have been uſed for tanning leather. All our domeſtic quadrupeds will eat the leaves [q], and therefore it is no bad plant in paſtures.]

27. This is a perennial plant. The ſtalks grow erect, about a foot high; they are very hairy. Leaflets oblong, ſerrate. The peduncles come out above the joints of the ſtalk. The flowers are white and large: they come out in june; and the ſeeds ripen in autumn.

[Linneus obſerves, that the leaflets are ovate, bluntly and equally ſerrate. He marks it as annual, but it is not.

Native of the South of France. Cultivated by Mr. Miller, in 1759 [r].

28. Root annual, fibrous. Stems ſeveral, a foot high, at firſt erect, roundiſh, with ſpreading hairs. Leaves petioled, having ſpreading hairs ſcattered over both ſides, ſerrate-toothed: leaflets oblong, veined. Branches from the axils. The upper part of the ſtem is dichotomous, and the leaves there become oppoſite and ſubſeſſile. Peduncles naked, one-flowered from the diviſions. Petals yellow, entire; the ſtamens and piſtils are of the ſame colour, but the ſtigmas are blackiſh. Stipules half-cordate, gaſhed or toothed, eſpecially in the lower leaves [s].

Seeds, according to Gærtner, ſmall, ſubovate, above obliquely mucronate, compreſſed like a lens, marked with wrinkles downwards, diverging towards each edge of the ſeed, of a yellowiſh bay colour. Coats three: *outmoſt* coriaceous, wrinkled; *middle* cruſtaceous, ſmooth, thickiſh; *inmoſt* membranaceous, of a red ferruginous colour. The ſeeds are wrinkled in almoſt all the ſpecies.

Retzius remarks, that it puts forth the upper peduncles from the forkings of the branches, but the lower from the branch itſelf, at a diſtance from the axil.

Native of Norway, Sweden, Pruſſia, Sileſia, Switzerland, Canada, Siberia. Linneus ſays that it has migrated from Norway into Sweden.

29. Stem herbaceous, aſcending, quite ſimple, a ſpan high, with villoſe hairs thinly ſcattered over it. Leaves heaped at bottom, but only one or two on the ſtem: leaflets ſmooth, veinleſs, acute at the baſe, bluntly three-toothed at the top, almoſt equal only the ſide ones narrower. Floral leaves three-parted, ſeſſile, lanceolate at the baſe and in the middle of the peduncles. Petioles linear, channelled, the length of the leaflets. Stipules lanceolate. Peduncles bifid at top; peduncle at the fork leafleſs, one-flowered. Calycine leaflets lanceolate, hairy. Germs hairy [t].

Native of Newfoundland and Groenland. Introduced in 1766, by Benjamin Bewick, Eſq. It flowers in june [u].

30. This has the ſtructure of *P. verna*, or the leaves of *P. argentea*, but ternate and wider, more hirſute, and ſnow-white underneath. Corolla yellow. The Lapland plant has larger leaves, ſmoother on the upper ſurface than the Siberian [x].]

[o] Afzelius in Withering. [p] Woodville. [q] Curtis. [r] Hort. kew. [s] Linn. ſuec. [t] Vahl. [u] Hort. kew. [x] Linn. ſpec. and ſuec.

31. Root perennial. Stems trailing. Leaflets ovate, obtuſe, bluntly indented on their edges. Flowers larger than in the *monſpelienſis*, and the whole plant of a deeper green. It flowers in july, and the ſeeds ripen in autumn.

[Linnæus marks it as annual, but there is little doubt of its being perennial. He obſerves that the leaves are of the ſame colour on both ſides, not ſilvery underneath; and that the ſtems are a foot high, aſcending, and ruſeſcent.

Culture, ſays Mr. Curtis, is known to produce great alterations in the appearance of moſt plants, but particularly in thoſe which grow ſpontaneouſly in dry mountainous ſituations: this is ſtrikingly exemplified in this ſpecies of *Potentilla*, which becomes in every reſpect much larger, as well as much ſmoother than in its natural ſtate.

Native of Switzerland, Dauphiné, the Pyrenees and Siberia. Cultivated by Mr. Miller in 1768 [y].

32. Leaves wrinkled, coriaceous, wedge-ſhaped, blunt. Stipules wide, acute, hairy. Stem or ſcape decumbent, often longer than the leaves, two-flowered or one-flowered. Corolla very large, yellow: petals emarginate, paler yellow at the baſe. Stamens yellow [z].

Native of the South of France, Granada, Siberia, Japan.]

PROPAGATION AND CULTURE.

1. The beſt ſeaſon for tranſplanting the Shrubby Cinquefoil is october, that it may get new roots before the hard froſt ſets in; for as it grows naturally upon moiſt boggy land, when removed in the ſpring, if due care be not taken to water it in dry weather, it is apt to miſcarry; nor will this plant live in a dry hot ſoil, but in a ſhady ſituation and on a cool moiſt ſoil it will thrive exceedingly.

2 and 26. Are common weeds, increaſing much by roots or runners.

3, &c. Moſt of the other ſpecies are eaſily increaſed by ſeeds, or parting the roots, or both. Autumn is the time for ſowing, parting and tranſplanting.

6. Loves a moiſt ſoil and ſhady ſituation.

22. This may be increaſed by runners like the Strawberry, in autumn. It loves a cool ſoil and a ſhady ſituation.

27. If the ſeeds are permitted to ſcatter, they will produce plants in plenty the following ſpring.

31. This will alſo come up from ſeeds, or the roots may be parted.

[POTENTILLA. See *Comarum*, *Fragaria*, *Tormentilla*.]

POTERIUM (*of Pliny*. Ποτηριον *of Dioſcorides*; *from* ποτηριον, *a cup*.)

GENERIC CHARACTER.

* *Male Flowers* in a ſpike.

CAL. *Perianth* four-leaved: *leaflets* ovate, coloured, caducous.

COR. four-parted: *ſegments* ovate, concave, ſpreading, permanent.

STAM. *Filaments* very many, (thirty to fifty) capillary, very long, flaccid. *Anthers* roundiſh, twin.

* *Female Flowers* in the ſame ſpike above the males.

CAL. *Perianth* as in the male.

COR. one-petalled, wheel-ſhaped. *Tube* ſhort, roundiſh, converging at the mouth. *Border* five-parted: *ſegments* ovate, flat, reflex, permanent.

PIST. *Germs* two, ovate-oblong, within the tube of the corolla. *Styles* two, capillary, coloured, flaccid, the length of the corolla. *Stigmes* pencil-form, coloured.

PER. *Berry* formed of the tube of the corolla, hardened, thickened, cloſed.

SEEDS two—inverted, *Gærtn.*

OBS. P. ſpinoſum *has a fleſhy globular berry, with oblong, cylindrical ſeeds.*

P. Sanguiſorba *has a juiceleſs angular berry, with four-cornered ſeeds acuminate at both ends; and two weak piſtils inſerted into the male flower.*

Calyx two, three or four-leaved. Reich. *four-parted, ſuperior*, Gærtn.

Gærtner, who joins this genus with Pimpinella, calls the fruit a drupe.

ESSENTIAL CHARACTER.

MALE. *Cal.* four-leaved. *Cor.* four-parted. *Stam.* thirty to forty.

FEM. *Cal.* four-leaved. *Cor.* wheel-ſhaped, five-parted. *Piſt.* two. *Berry* formed of the hardened tube of the corolla.

DESCRIPTIONS, *&c.*

1. [The common, ſmall or upland Burnet has a perennial root, penetrating deep into the earth. Stems nearly upright, from nine inches to a foot high:] Mr. Miller ſays, a foot and half, [as it is in cultivation: branched, ſtriated, reddiſh, ſmooth except at bottom, where they are ſlightly hairy. Leaves unequally pinnate, on pretty long peduncles, next the root collected into a tuft, on the ſtem alternate. Leaflets ſmooth, pale or bluiſh underneath, deeply ſerrate about the edge, the lower ones on the ſame leaf commonly alternate, and the upper ones oppoſite. The bottom leaves have ſeven or eight pairs of roundiſh leaflets; the ſtem-leaves have five or ſix or at top only two pairs of ovate pointed leaflets. The petiole is three-cornered, channelled, hairy, and ſome-

[y] Hort. kew. [z] Linn. ſpec.

ſomewhat membranaceous at the baſe. Stipules toothed. Flowers peduncled in little roundiſh heads; greeniſh, ſometimes purpliſh on the outſide, the terminating one largeſt: each head has male flowers below, and female or fertile flowers above, expanding before the former, which are frequently imperfect hermaphrodites. Calyx two, three or four-leaved, inferior. Corolla four-parted. Filaments twenty or more, very long, commonly red. Stigma very red [a]. Linneus conſiders the fruit as a Berry formed of the calyx hardened; according to Gærtner it is a Drupe, which in this ſpecies is ovate, acuminate at both ends, quadrangular with the angles compreſſed and ſharp, wrinkled with little excavations at the ſides: rind coriaceous, of a yelloviſh bay colour, or ſometimes reddiſh: ſhell the ſubſtance of paper, ovate, two-celled. Seeds ovate-acuminate, plano-convex, pale yellow, with a ferruginous area at the baſe.

Leers remarks, that the male flowers have a germ and ſtigmas, but all imperfect and barren, as in *Valeriana dioica*: Curtis—that the ſtyles are ſhorter and the ſtigmas leſs expanded; both calyx and corolla larger.

This has the habit of the Great Burnet, (Sanguiſorba officinalis) and the fruit bears a near reſemblance. But that is a coarſer larger plant, and grows in moiſt meadows; it has only hermaphrodite flowers, and differs from this in the number and diſpoſition of the ſtamens. The ſtems of upland or leſſer Burnet are not ſtiff and upright, but rather declining; the lower leaflets rounder; the heads ſometimes purpliſh when in fruit; but never of ſo deep a tinge or ſhining, as in the Great Burnet.

Native of England, Germany, Switzerland, in high dry paſtures, in a calcareous ſoil; flowering in may, and ſometimes in april.

The leaves, when bruiſed, ſmell like Cucumber, and taſte ſomething like the paring of that fruit; they are ſometimes put into ſalads and cool tankards.

The leaves and ſeeds are mildly aſtringent, and have been uſed in dyſenteries and hæmorrhages.

Some years ſince Mr. Rocque attempted to bring Burnet into uſe as an early ſpring-feed for cattle, and it was ſaid to grow ſo faſt as to allow of being mowed three times during the ſummer.

On the ſubject of ſo doubtful a plant it may not be amiſs to ſtate the moſt material evidence on each ſide.]

Mr. Miller ſays, this plant has been of late recommended by perſons of little ſkill, to be ſown as a winter pabulum for cattle; but whoever will give themſelves the trouble to examine the grounds where it naturally grows will find the plants left uneaten by the cattle, when the graſs about them has been cropped to the roots; beſides in wet winters and on ſtrong land the plants are of ſhort duration, and therefore very unfit for the purpoſe, nor is the produce ſufficient to tempt any perſons of ſkill to engage in its culture.

[Burnet, ſays Mr. Curtis, is one of thoſe plants which has for ſome years paſt been attempted to be introduced into agriculture, but not anſwering the farmer's expectations, is now in a great degree laid aſide. Cattle are ſaid not to be fond of it; nor is its produce ſufficient to anſwer the expenſe attending its culture. It is to be lamented that perſons do not pay a little more attention to the nature of plants before they ſo warmly recommend them. It ſeems very unlikely that a ſmall plant, ſcarce ever met with but on hilly and chalky ground, and to which cattle in ſuch ſituations do not ſhow any particular attachment, ſhould afford better, or more copious nouriſhment, than the Clovers and other plants already in uſe. It is not meant by this however to diſcourage that laudable ſpirit of improvement which ſo happily prevails at preſent; but to caution ſuch as introduce any new plant, to make themſelves well acquainted with its natural hiſtory.

According to Mr. Boys, in the Agricultural Survey of Kent, it affords herbage in the winter and ſpring months, but is not much liked either by cattle or ſheep.

Dr. Anderſon reports, that Burnet retains its verdure pretty well during the winter months, but affords ſuch ſcanty crops, as hardly to be worth the attention of the farmer [b].

A correſpondent in the Muſeum Ruſticum, a work very favourable to Burnet, confeſſes with reluctance that it is not deſerving of any exalted character, but rather the contrary; and that it is in no degree to be compared to the common Clover, which is cultivated at half the expenſe [c].

It appears from ſome accounts there that horſes will not eat it at all, and that kine frequently will not take it without great reluctance. Its ſlow growth is alſo made a great objection: being only about five inches high, and having ſcarce one head in flower; whilſt Lucerne, on the ſame ſoil, ſown the ſame day and much thicker, was eighteen or twenty inches in height [d].

A Warwickſhire correſpondent in the ſame work, ſays it is a general rule with ſurveyors on encloſures in that county, to ſet land abounding in Burnet at the loweſt quality. He attributes its keeping long green to a pungent oil with which it abounds; this oil preſerves it from froſt, but at the ſame time makes cattle not fond of the hay; it heats their mouths, and after a day or two they will rather eat ſtraw [e].

Certainly Burnet, in its wild ſtate, is generally ſmall, dry and not ſucculent. Cattle and even ſheep will not eat it when it is run up to ſtalk. But this is not peculiar to Burnet; and we are not to judge of the value of plants in cultivation from the appearance they make when wild. Nor are we, from this difference of appearance, to conclude, as ſome have done, that the wild and cultivated Burnet are ſpecifically different.

A gentleman farmer ſowed five acres of a poor ſandy ſoil, well prepared, with Burnet ſeed, bought of Mr. Rocque, twelve pounds to the acre, in the month of auguſt. The firſt ſeaſon it ran all to ſtalks, with few leaves, ſo that he had not above ſeven hundred weight of hay from each acre, and that very bad. The next year the crop was ſtill worſe, perhaps owing to a long drought. However he was diſſatisfied with it, and finding Saintfoin much ſuperior on his land, ordered the five acres to be ploughed up [f].

Others affirm that Burnet is ſo ſtalky and ſtiff, that it is more fit for fuel than hay; that horſes will ſooner eat their litter than this plant; and that even ſheep will rather eat the hedge round the cloſe than the crop of Burnet in it [g].

But let us now attend to the other ſide of the queſtion.

Mr. Rocque, of Walham Green in the pariſh of Fulham in Middleſex, firſt introduced Burnet to public notice, as food for cattle, about the year 1760, at the recommendation, as it is ſaid, of Mr. Wyche, who firſt gave Rocque the *Bird-graſs*, which is a ſpecies of Poa; and, as I believe, the *Timothy-graſs* or *Phleum pratenſe*.

Rocque's own account of it is, that it is always in ſap, and that you can have the green feed from the middle of ſeptember, till february, march and april, which are the months when other graſſes are commonly ſcarce. He directs it to be fed from february to the firſt of may: to be mowed for ſeed about the middle of june, and to be threſhed between wet and dry, leaving part of the ſeed with the hay, which will be as good as corn and hay together, even if the ſeed is not amongſt it. It muſt be mowed again in the middle of ſeptember, and threſhed like the firſt. Mr. Rocque adds, I now (december 1763) actually keep a horſe with only the Burnet hay or ſtraw, and every body is aſtoniſhed to ſee how well he looks: and Burnet is of ſuch a ſtrong nature, that when horſes feed upon it, their fleſh is ſo firm, that the higheſt-kept horſes are not to be compared to thoſe fed upon Burnet, for firmneſs of fleſh. The chaff, he believes, is as good as Pollard for a horſe; and in his

[a] Curtis, Stokes, Fl. ruſtica.

[b] Eſſays, 2. 46. [c] Vol. 6. 157. [d] Id. 5. 253. 257. [e] Id. 4. 36. [f] Id. 5. 157. [g] Id. 5. 297. 300.

opinion, when cattle are fed upon it, we ſhall have firmer meat than ever we had [k]. When horſes have the greaſe, he adviſes them to be turned in upon the Burnet, but obſerves, that it is only the firſt crop which has this effect. He affirms that it is always green, even when the ſeed is ripe; and that no dry weather ſtops or injures it; inſomuch that he has ſeen Fennel periſh, whilſt Burnet remained green and thriving [l].

Large allowance is to be made for the partiality and feelings, both of a man who has introduced a new object to public notice, and of thoſe who from ſome cauſe have been diſappointed in their great expectations.

A neighbour of Mr. Rocque's, early in november 1763, ſaw his plot of Burnet: it had been cut at the end of ſeptember, looked then very freſh and vigorous, and had acquired a conſiderable growth ſince the cutting. He alſo ſaw ſome hay made of it, in Mr. Rocque's barn: it was not bad, but would have been excellent had it not been left till the ſeed was perfected, and had it not been got up in a wet ſeaſon. The beſt time, he juſtly ſays, to make Burnet into hay, is juſt before it begins to flower, as it is then fulleſt of ſap, tender and nouriſhing: when the ſeeds are left to perfect, the ſtalks are apt to grow ſticky.

Burnet, he adds, is not only a wholeſome food for cattle, but they are remarkably fond of it both in a green and dry ſtate: this, with its vegetating in the cold winter months, ſhould induce farmers to ſow it, eſpecially as there is no fear of its thriving in almoſt any ſoil, and it is a quick grower [m].

Mr. Rocque himſelf informs us in another place that the firſt crop of Burnet purges horſes, as well as the ſtrongeſt phyſic, for three days ſucceſſively; and that being at Lord Uxbridge's in auguſt 1764, he ſaw ſix horſes feeding upon three acres of Burnet: they had been turned upon it three weeks and four days; they purged exceſſively the three firſt days, but the fourth day it ſtopped, and they then throve amazingly. The Burnet grew faſter than the horſes could eat it, though the land is gravelly and full of large ſtones [n].

Mago, who was a well known character, and a very good farmer, informs us, that he rode ſeveral times during the winter of 1764 5 by Mr. Rocque's Burnet; that there were four acres of it; that they looked ſurpriſingly well, and were a fine deep feed [o].

This gentleman having firſt heard of Burnet in the ſpring of 1763, in july 1764 ſowed a piece of ground with five pounds of Rocque's ſeed; and in the october and march following planted it out on four acres of light hot land: the ſummer was very dry, his plants however ſtood it out, and were of a beautiful verdure; the weeds were kept down, and about 160 pounds of ſeeds were collected by hand: part was then mowed, and afterwards four cows and two horſes were turned into the field. The cows ate very freely, preferring the lower part as being moſt leafy; the horſes took ſtalks and all without diſtinction: but at firſt the horſes did not ſeem to like it ſo much as the cows. After theſe had been two or three days on the Burnet, the butter and cream were perceptibly improved in flavour. The coach-horſes lived upon it near a month, and throve very much, after a day or two [p].

Chriſtopher Baldwin, Eſq. of Clapham Common made ſeveral experiments on Burnet in the years 1763 and 1764. In july 1764 he ſowed eight rods of ground with five pounds of Rocque's ſeed, and in the autumn and ſpring following tranſplanted it on four acres. The plants were once hoed, and ſtood over for ſeed. When that was got, four cows and two horſes were turned in. The cows fed freely on it, but the horſes did not ſeem to like it much at firſt, though in two or three days they fed well upon it. In four or five days the cows increaſed much in milk, and the cream was ſuperior in flavour. The horſes were afterwards fed in the ſtable about five weeks with the haulm from which the ſeed had been thraſhed; and they throve much upon it, though they had only half their allowance of oats. The next winter four cows were turned in, which were in very good feed on natural graſs, and had beſides a large truſs of oat-ſtraw put in their cribs every night, yet they gave very little milk, and indeed were almoſt dry. They had not been in the Burnet above ſix days, before they gave much more than double the milk, of an exceeding fine quality, and ſoon began to leave half their ſtraw in the cribs. Mr. Baldwin's land is dry poor upland gravel [q].

The Earl of Northington ſowed an acre of Burnet at the Grange by way of experiment. The ſoil was light, but rich enough for wheat or any other common grain. It was ſown by itſelf broadcaſt, kept clean, and mown once the firſt year; the ſecond twice, once for ſeed, and once for green food: horſes, hogs and ſheep fed freely on it, which was ſuppoſed to depend upon not giving it them when too old and ſtalky. When Mr. Young ſaw it in 1767, it was two years old that ſpring, was ſtanding for a crop of ſeed, not having been cut that ſeaſon, and was a very fine thick crop, of great bulk, with very few weeds in it [r].

Mr. Johnſton of Iſford had one rood drilled in rows two feet aſunder, and one acre in rows at three feet diſtance; both very fine crops in 1767. The year before he fed cows and horſes with the produce of the rood; both eat it very freely, and even with greedineſs. The land is dry and gravelly [s].

Mr. Young alſo viewed an acre of Burnet at Stoak in Norfolk, which was three years old in 1767: it was ſown broadcaſt on a good loam, and kept perfectly clean from weeds a year at the expenſe of above two guineas; but it anſwered very well, for it has every year yielded a great quantity of hay, beſides luxuriant food ſo early as the month of february for many horſes. It was a regular crop, and appeared to grow very quick [t]. He remarks that Lord Clare had a piece of Burnet at Goſfield for his deer in winter, which anſwered extremely well [u].

Mr. Young obſerves, it appears extremely clear from theſe minutes, that the idea of cattle diſliking Burnet is a moſt miſtaken one: and that the trial at Stoak is perfectly ſatisfactory, particularly in the point of having a luxuriant head of food for ſheep and horſes in january and february, which no other graſs would give [w].

Mr. Young relates an experiment made by Mr. George Siſſon, a farmer of Bridge Caſterton in the county of Rutland, in may 1767, upon an acre of light ſandy land, in Ingthorp lordſhip, which turned out very advantageouſly, and when Mr. Young ſaw it was a fine after-crop, the firſt having been mowed for hay. He ſowed fourteen pounds of ſeed, and in july 1768 he mowed it, and having threſhed it, he had twenty-three buſhels of ſeed, which weighed five hundred ſixty-two pounds and a half [x].

Sir Digby Legard, in april and may 1766 and 1767, ſowed twelve acres with Burnet ſeed, twelve pounds to the acre, on light loam well prepared; the ſeed was ſown by hand and without corn. The firſt year's crops were a ton on an acre; the next year better, but the third much inferior. The produce of ſeed very great. The hay is coarſe, but cattle will eat it. Cows and horſes in general eat it very greedily, but ſome horſes diſlike it at firſt. Three acres yielded fourteen buſhels of ſeeds in 1767, one buſhel of which weighed twenty-four pounds [y].

Mr. Searanche, at Hatfield, on an upland gravel, ſowed Burnet by itſelf, after a complete fallow and manuring with ſaintfoin, and alſo with oats. It was kept clean for a year by hand work. For hay he eſteems it as nothing; but good for cows, making fine butter; and alſo very early for ſheep. It ſtands the rigour of the ſevereſt winter without being damaged.

Mr. Dalton, at Sleningford, on a ſhallow light loam on limeſtone, ſowed five acres with barley in 1767. It was ſed down the firſt ſpring by forty ſheep, three weeks in april, after which it ſtood for hay, and yielded

[k] Id. 1. 298, 308. [l] Id. ib. 462. [m] Id. ib. 229. [n] Id. ib. 230. [o] Id. 4. 177. [p] Young's Six week's tour. 5. 204. [q] Id. 237. [r] Id. 1. 33. [s] Id. 2. 75. [t] Id. 7. 346. [u] Six month's tour through the north of England, 1. 71. [w] Id. 2. 41.

a large

a large cart load by the acre. Very good, and eaten freely by cattle.

From theſe trials, Mr. Young obſerves, it appears clearly, that Burnet will abide the winter's froſt, yield plenty of green feed early in the ſpring, and make cows yield very fine milk; and that horſes feed on it both green and in hay.

There is only one minute againſt it, which is Mr. Hewet, of Bilham, on a fine light hazel mould, in drills, and kept perfectly clean. He ſays, no cattle whatever would eat it, unleſs abſolutely forced by hunger [r].

Mr. Young, in his Eaſtern Tour [s], ſays that in ſumming up his intelligence concerning Burnet in his tour of 1768, he found the accounts very contradictory. That it is a good paſture in ſome places, and a bad one in others, he juſtly looks upon as highly improbable; and imputes the diverſity of accounts to circumſtances unrelated, or in ſome inſtances perhaps to prejudice.

Cattle, he obſerves, may have been turned into it, after it had got a head and was near ſeeding; then it is generally agreed they will not touch it. But ſo it is with Ray-graſs; what is that good for as feed after midſummer?—The ſeed of Burnet having fetched a good price, much has been ſeeded, and the *ſtraw* has been too often confounded with the *hay*. The original intention of it was for a winter paſture; and in that ſeaſon cattle will eat and thrive on food, which at other times they will not touch: this has not been ſufficiently attended to. Cattle may have been turned into a Burnet field ſo hungry, that they might feed on it for a time, without proving it to be good food in general. From actual practice however ſeveral facts may be deduced.

Firſt, the balance of the account is greatly in favour of Horſes eating it in the common manner of all other food.

Secondly, we cannot deny it to be a good food for Sheep, and the balance of intelligence lies much in favour of it.

Thirdly, in a few inſtances Cows and Oxen diſlike it, but in many they eat it freely.

Upon the whole the reports are favourable: but the proper application of Burnet ſeems to be, to leave it a good head in autumn ready for ſheep in the ſpring, for them to keep it down as cloſe as poſſible about two months, upon the plan of Ray-graſs; and after that to let it ſtand for a crop of hay.

But the moſt advantageous method ſeems to be, to ſow it with other graſſes in laying down land to paſture.

Since theſe obſervations of Mr. Young's were made, there have been other trials of Burnet.

Mr. W. Pitt, of Pendeford near Wolverhampton, in april 1783, ſowed an acre of Burnet inſtead of the uſual ſeeds, in the midſt of a field of barley, the reſt of the field being ſeeded with clover and ray-graſs. The ſeeds came well, and the following autumn it was paſtured with ſheep and horned cattle. The ſheep preferred the clover and ray-graſs; but the horned cattle ſeemed to prefer the Burnet. It was hayed up at Chriſtmas, and notwithſtanding the great inclemency of the weather at Lady-day, the Burnet was a good picking for cows. It evidently preſerved its verdure in ſevere weather much beyond clover [t].

The ſame excellent cultivator, in his Agricultural Survey of Staffordſhire ſays, that Burnet has been ſown by many perſons there of late years, and by ſome on a broad ſcale; that he knows it by experience to be a valuable addition to cow paſtures; cows preferring it to clover: that Mr. Miller, a very attentive neighbour of his, who keeps a large dairy, and has for ſome years back ſown large quantities of it, is ſo very partial to Burnet, that he would have ſown ten hundred weight of the ſeed, could he have procured it. Certainly, ſays Mr. Pitt, it is a good mixture with other herbage, with which it interferes little, drawing its nouriſhment deep from the earth by a long tap root. He thinks that ſheep and horſes prefer clover, and he allows that it is by no means ſo productive as broad clover, by one third.—However he eſteems it a good plant to ſow inſtead of ray-graſs with clover or treſoil, being abiding, and extremely hardy, bidding defiance to froſt, coming very early in the ſpring, and ſuſtaining the chilling blaſts of the eaſt wind without fading. It has alſo the property of preſerving hay from overheating in the ſtack [u].

That ſheep eat wild Burnet when young appears from many of our chalk downs, particularly Saliſbury-plain between Saliſbury and Everley, where this plant forms almoſt the whole ſtaple of the herbage over a great extent of that moſt excellent ſheep-walk. It is kept ſheared very cloſe by the large flocks which depaſture on it every day, except here and there a flower-ſtem which is left growing. Hence Dr. Withering obſerves, he has no doubt but that it is a moſt valuable plant in hard-ſtocked ſheep paſtures [x].

To aſcertain how far ſheep are fond of cultivated Burnet, Thomas Le Blanc, Eſq. of Cavenham in Suffolk, in october 1782, ſowed a ſpace, ſeveral perch ſquare, with Burnet-ſeed and rye, being part of a hundred acres laid to ray-graſs, treſoil and white clover; the ſoil a blowing ſand upon a chalk bottom. It was folded for the rye. The 5th of april 1784 between ſix and ſeven hundred ſheep were turned in. The graſſes were in general backward, but the Burnet was much forwarder than the reſt. For the firſt two or three days they did not eat it at all; but a fortnight after it was eaten to the ground, and on the 4th of june it was pared cloſe. When a ſtock has ſo large a range as a hundred acres, and the growth of any ſmall ſpot is eaten up ſo clean, it is a far more ſatisfactory proof that the ſheep have no diſlike to the plants growing there, than if they were confined to a ſmall field with no other herbage [y].

On this deciſive experiment Mr. Young makes the following very pertinent obſervations.—On three-fourths of the ſheep-walks in England, ray-graſs is the only plant uſed, or ſometimes broad clover on ſoils much too poor for it. Granting the neceſſity of ſome ray-graſs, is it not a great object to introduce other plants, not ſo exhauſting, that ſhall have the ſame or ſuperior qualities? There is no doubt of the exhauſting quality of ray-graſs; but the broad leaf of Burnet, and its deep carrot root indicate the contrary effect, and accordingly in ſeveral trials it has been found to ameliorate. The pooreſt ſoils in the kingdom agree well with it; and the hot pungent quality of the plant has been found exceedingly beneficial to ſheep touched with the rot.

The aſſertions that were made for ſome years againſt Burnet reſulted from attempting to feed it when too much grown. The right time to feed it with ſheep is while it is in its young yellow ſhoot, and in that period of its growth nothing refuſes it.

Mr. Le Blanc alſo, in the ſpring of 1788, laid down an acre of incloſed good but looſe ſand, with ten pounds of Burnet ſeed. He kept it in autumn for ſheep feed, and fed it bare in the ſpring accordingly. At the end of may it was riſen again to be a fine regular growth, and produced ſeven buſhels of ſeed. In the ſpring of 1790 he fed it again with ſheep. In part of the ſame field were turnep-rooted cabbages. When ſheep and cows were turned in promiſcuouſly they did not begin the burnet till the cabbages were eaten; but at laſt they eat it bare as a board to paſt the middle of april [z].

J. William Allen, Eſq. of Whipſtead made an experiment on a ſtrong tenacious loam, on a clay bottom. Five roods of this land were ſummer-tilled in 1791, and in the ſpring of 1792 ſown with barley, at the ſame time twenty-eight pounds of Burnet were harrowed in. The Burnet looked well after harveſt, and at michaelmas was about ſix inches high. The 5th of april he turned in thirty Norfolk ewes and lambs; they eat it greedily, and in three weeks had trimmed it ſo

[r] Id. vol. 4. p. 70. [s] Vol. 4. p. 131. letter 35.
[t] Young's Annals, 1. 394.
[u] Idem, 3. 366.
[x] Arrangem. of Brit. plants, p. 494. ed. 3. note.
[y] Young's Annals, 2. 168. [z] Idem. 16. 355.

much as to become reſtleſs, and were therefore removed. On the 1ſt of may nineteen Leiceſter ewes with twenty-three lambs were turned in till the 10th, when the field was ſhut up for ſeed. It was mowed on the 20th of july, and produced three quarters and two buſhels of clean ſeed. The ſtraw was laid up for winter proviſion for ſheep; and the horſes are very fond of the chaff[f].

Robert Proctor Anderdon, Eſq. thinks Burnet ſo healthy a graſs for ſheep, that he earneſtly recommends it to all farmers to interſperſe ſome of it in every field ſown with graſs-ſeeds to remain in paſture; for he conceives it to be warm and aſtringent, having put ſheep that ſcoured into ſuch of his fields as abound with it, by which they have ſoon been viſibly benefited[g].

His cows, in a dry ſummer, being put into an old hilly paſture, where Burnet grows naturally, produced an amazing increaſe of milk[h].

From the above accounts we may collect the utility of this plant properly cultivated on a ſuitable ſoil. The produce of it, both in hay and ſeed is conſiderable; the paſturage, not only in autumn and ſpring, but in winter, maintaining its growth and verdure in drought and froſt, render it particularly valuable; in general cattle and ſheep are fond of it, and grow fat by it; the milk, cream and butter of cows feeding on it are excellent in quality and great in quantity: it will flouriſh and afford large crops on ſandy, gravelly and ſhaley ſoils. Theſe are valuable qualities, and yet Burnet is not cultivated to any great extent, nor is it generally admitted that cattle and ſheep will always eat it; and with reſpect to horſes many deny that they will crop the herbage willingly[i].

There are ſome varieties of the common upland Burnet ſcarcely worth mentioning: as one that is much ſmoother; a ſecond that has no ſmell; and a third with larger ſeeds.

The differences between this and the great Burnet (Sanguiſorba officinalis, *Linn.*) have been given above. Some confuſion has ariſen from the Burnets and Burnet-Saxifrages having all had the name of *Pimpinella* in old authors. The Burnet-Saxifrages (Pimpinella Saxifraga et magna, *Linn.*) are, as all botaniſts know, extremely different, being umbellate plants. Dr. Anderſon ſtill calls the cultivated Burnet *Pimpinella ſylveſtris*, which is the name of the Great Burnet in Gerarde's herbal.

2. Stem the thickneſs of the finger, rough with the dried rudiments of the petioles. Leaves unequally pinnate, very ſmooth, ſhining above, paler underneath. Petioles cluſtered on the top of the ſtem, ſheathing at the baſe. Leaflets nine to nineteen, ſuboppoſite, ſeſſile, truncate at the baſe. Flowering branches ſlender, angular, procumbent. Leaves on them few, with roundiſh leaflets, ſometimes obovate or even linear. Peduncles few, long, unequal. Head of flowers long. Germ inferior, four-cornered. Calyx four-parted. Stamens about twenty; with violet-coloured filaments. Drupe wrinkled, ſharp-pointed at both ends, coriaceous.

Native of Barbary near Tlemſen, in the fiſſures of rocks; flowering early in ſpring[k].]

3. This is a biennial plant, decaying ſoon after the ſeeds are ripe. Leaves like thoſe of Agrimony, compoſed of three or four pairs of oblong leaflets, placed a little alternate; they are deeply indented, and have an agreeable ſcent. Stems two feet high, with one of theſe leaves at each joint, gradually diminiſhing in ſize to the top; and juſt above the leaf ariſes a long peduncle, which ſupports two or three ſmall ones, each ſuſtaining a ſmall roundiſh ſpike of flowers. Theſe appear in july, and are ſucceeded by ſeeds which ripen in autumn.

[Desfontaines remarks, that the whole plant is villoſe, and of an aſh-colour; the leaflets ovate.

The drupe is ſmalliſh, ovate-oblong, attenuated to both ends, wrinkled, obſcurely four-cornered, bay-coloured, one-celled: rind coriaceous, thin: ſhell cartilaginous, ferruginous on the outſide. Seed cylindric-acuminate, bay-coloured[l].

Native of the South of France, Italy and Barbary. Cultivated in 1683, by Mr. James Sutherland[m].

4. Native of the Canary Iſlands, where it was found by Mr. Francis Maſſon. Introduced in 1779. It flowers in march and april[n].]

5. This has a ſhrubby ſtalk, riſing about three feet high, and dividing into ſeveral ſlender branches armed with ſharp branching thorns. Leaves very ſmall, unequally pinnate with ſix or ſeven pairs of oppoſite leaflets, of a lucid green and continuing all the year. Flowers of an herbaceous colour, in ſmall heads at the ends of the branches: they appear the beginning of june, and there is a ſucceſſion of them moſt part of the ſummer; but thoſe only which come early, are ſometimes ſucceeded by ſeeds in England.

[Drupe globular, obſcurely angular towards the baſe, red: rind ſpongy, very thick: ſhell elliptic, ſharp-pointed at both ends, bony, two-celled. Seeds ſemi-cylindrical, pale yelloviſh, with a cheſtnut-coloured area at the baſe[o].

Native of the Levant; the foot of Libanus, Candia and ſeveral iſlands of the Archipelago.—Cultivated by Gerarde in 1596[p].]

PROPAGATION AND CULTURE.

1. Common or Small Burnet is eaſily propagated in gardens for ſalads, &c. by ſeeds ſown in autumn, ſoon after they are ripe. If ſown in the ſpring, the ſeeds frequently lie in the ground till the ſpring following. If the ſeeds be permitted to ſcatter, the plants will come up in plenty; and if theſe be tranſplanted into a bed of undunged earth, at about a foot diſtance every way, and kept clean from weeds, they will continue ſome years without farther care, eſpecially if the ſoil be dry. Burnet may alſo be increaſed by parting the roots in autumn, but as it grows ſo freely from ſeeds, this method is ſeldom practiſed.

[*Field Culture of Burnet.*

Mr. Rocque directs the ground to be prepared for Burnet in the ſame manner as for Lucerne; to be ploughed or trenched as deep as the ſtaple will admit, and to be well dunged: the ſeed to be ſown broadcaſt without corn, twelve pounds to the acre, in april, or any of the ſucceeding months till auguſt; before ſowing, harrow and roll; after ſowing, harrow with a light harrow and roll again; ten days after the ſeed will come up with a round leaf; but it is generally ſaid by others that the ſeed takes about twenty-three days to vegetate: keep the crop very clean the firſt year, and it will keep itſelf clean afterwards[q].

Unleſs it be ſowed early, Burnet muſt not be grazed the ſame ſummer, becauſe when young it bleeds too much; but it ſhould be left till february or march; it may then be fed till the beginning of may, when the cattle ſhould be taken out, and it may be mowed for ſeed about the middle of june.

For Burnet after Turneps, Mr. Rocque directs, after the Turneps are cleared off, ſuppoſe in march, to plough the ſame depth as was ploughed for the Turneps; then about the middle of may to trench-plough it, to break the ſtaple, and facilitate the growth of the roots; in the middle of june trench-plough again, but no deeper than the firſt time, not to bring up the dead earth. Harrow and roll well, and then ſow; after which run a light harrow over it, not to bury the ſeed too deep, and roll it again: then let it lie till auguſt, when if there are any weeds harrow backwards and forwards, and if there ſhould be occaſion hoe or hand weed it[r].

A dry ſoil ſuits Burnet beſt. It grows in ſtony and gravelly lands, but its natural bed is calcareous. The ill ſucceſs which has ſometimes attended this crop may perhaps be owing to its having been ſowed in a ſoil improper for it. We have ſeen however that

[f] Id. 21. 171. [g] Bath papers, vol. 2. p. 58. [h] Id. ib. p. 60. note. [i] Muſeum ruſticum, vol. 6. 159. note, and 240. note. [k] Desfontaines. [l] Gærtner. [m] Hort. kew. [n] Idem. [o] Gærtner. [p] Hort. kew. [q] Muſ. ruſt. 1. 196. [r] Id. ib. 469.

it ſucceeded in one inſtance in ſtrong land, but perhaps the ſubſoil was marly. It will not do where water ſettles on the ſurface, or on a wet bottom.

Burnet will not ſucceed on new broke-up land, but a crop of oats or potatoes ſhould firſt be taken. The ground ſhould be worked very fine for this crop[s].

Others have tranſplanted Burnet in rows with good ſucceſs.—Mago ſowed five pounds of Rocque's ſeed in the ſummer of 1764 broad-caſt after peas. At the end of auguſt, when it was ſix or ſeven inches high, he mowed it to deſtroy the weeds. It ſoon ſhot up again, and topt the weeds.

By the fourth of october having got two acres of light dry land, that had had a crop of oats, well ploughed twelve inches deep, he planted them with the Burnet; and though it was ſo late as from the fourth to the tenth of october, the plants in general took, vegetated through the winter, and in the ſpring were very promiſing: the rows were twenty inches apart, and the plants were fifteen inches from each other in the rows[t]. In march the ſame gentleman tranſplanted two acres more.

Mr. Baldwin alſo purſued the ſame method. In the beginning of july 1764 he ſowed about eight rods of ground with five pounds of Rocque's Burnet ſeed. Rain falling ſoon after, the plants came up and throve ſo well, that he ploughed up an acre of ground, and planted it on the fourth of october, in rows twenty inches apart, and fifteen inches aſunder in the rows. The plants took well, and throve through the winter with ſurpriſing vigour. In the ſpring he planted three acres more, and notwithſtanding the uncommon drought of the ſummer, the whole grew well, without being watered. The plants were once hoed, and ſtood over for ſeed. Cows and horſes were turned in, and they having fed it down, it was hoed again and harrowed once over.

Mr. Baldwin afterwards ſowed twelve acres broad-caſt, after oats, with 160 pounds of ſeed, on the 26th of auguſt: no rain falling till the 18th of ſeptember, the plants did not appear till the 28th. His land is poor dry upland gravel[u].

Other gentlemen have practiſed the drill huſbandry with equal ſucceſs, on Burnet. It has been ſown indifferently in ſpring and autumn, but moſt commonly in the former ſeaſon: with corn and without, but ſeemingly to moſt advantage alone.

For hay it ſhould be mown when in full bloſſom. When mown for ſeed, much of it will be loſt; for what is full ripe is apt to ſhed, and as it ripens ſucceſſively, ſome will be quite green, when the forwardeſt is quite mature.]

3. Sow the ſeeds in autumn, and the plants will come up in ſpring: thin them and keep them clean from weeds. The ſecond year they will flower, ripen their ſeeds, and decay.

4, 5. Theſe may be increaſed by ſlips or cuttings, planted in a bed of light earth, during any of the ſummer months; cover them cloſe with a hand or bell-glaſs and ſhade them from the ſun. When they have taken root, take them up, and plant them ſingly in ſmall pots, filled with freſh undunged earth. Place them in the ſhade till they have ſtruck root, and then remove them to a ſheltered ſituation. When froſts come on, place them under a hot-bed frame. They require little water, eſpecially in cold weather.

Lin. ſpec. Willd. 685. *Swartz, prodr.* 32. *deſcr.* 270. *Brown. jam.* 333. *n.* 13.
Dracontium ſcandens. *Aubl. guian.* 836. 3.
Leaves ovate-lanceolate entire nerved dotted.

6. Pothos craſſinervia. *Thick-nerved Pothos.*
Lin. ſpec. Willd. 685. *Jacqu. ic. rar.* 3. *t.* 610. *collect.* 4. 122.
Leaves oblong acuminate quite entire veined, with the midrib of the leaf three-keeled.

7. Pothos cordata. *Heart-leaved Pothos.*
Lin. ſpec. 685. *Reich.* 4. 76. *Willd.* 685. *Plum. ſpec.* 4. *ic.* 38. *fil. t.* 205. (Arum.)
Leaves cordate, lobes imbricate, ſpadix nearly equal to the ſpathe.

8. Pothos macrophylla. *Large-leaved Pothos.*
Lin. ſpec. Willd. 686. *Swartz, prodr.* 33. *deſcr.* 269.
P. grandifolia. *Jacqu. ic. rar.* 3. *t.* 610. *collect.* 4. 121.
Dracontium cordatum. *Aubl. guian.* 2. 836. *Plum. amer.* 48. *t.* 63.
Leaves cordate, lobes divaricate, ſpadix much longer than the ſpathe.

9. Pothos pinnata. *Pinnate-leaved Pothos.*
Lin. ſpec. 1374. *Reich.* 4. 77. *Willd.* 686.
Laſia aculeata. *Lour. cochinch.* 81. 103?
Appendix laciniata. *Rumph. amb.* 5. 489. *t.* 183. *f.* 2.
Leaves pinnatifid.

10. Pothos palmata. *Palmate-leaved Pothos.*
Lin. ſpec. 1374. *Reich.* 4. 77. *Willd.* 686. *Plum. amer.* 49. *t.* 64, 75. (Dracontium.) *fil. t.* 207, 208. *ſpec.* 5. (Dracunculus.)
Leaves palmate, lobes nine lanceolate blunt.

11. Pothos digitata. *Digitate-leaved Pothos.*
Lin. ſpec. Willd. 686. *Jacqu. ic. rar.* 3. *t.* 611. *collect.* 119.
Leaves digitate about nine oblong ſharpiſh.

12. Pothos pentaphylla. *Five-leaved Pothos.*
Lin. ſpec. Willd. 687.
Dracontium pentaphyllum. *Aubl. guian.* 2. 837. *t.* 326.
Leaves digitate quinate ovate acuminate.

13. Pothos fœtida. *Stinking Pothos* or *Skunk weed.*
Ait. kew. 3. 319.
Arum n. 12. *Mill. dict.*
Leaves cordate, ſpadix ſubglobular.

DESCRIPTIONS, *&c.*

1. This is a ſhrub climbing like Ivy, throwing out fibres as that does, by which it adheres to walls and the trunks

[s] Id. 4. 177. [t] Id. ib. 229. [u] Id. 6. 259.

trunks of trees. Branches round. Leaves diſtich, alternate, lanceolate, ſtriated, ſmooth, quite entire, on a membranaceous petiole, as in the Orange. Fructification axillary, ſolitary, peduncled, reflex [a]. Spike globular in this: oblong in the following ſpecies [b].

Loureiro deſcribes the leaves as much wider than the petioles, which are long, half embracing, and alternate. Flowers pale. Berries red, ſubovate, juicy, ſmall, containing one or two ſeeds.

Native of the Eaſt Indies and Cochinchina. Loureiro ſays that Rumphius's *Appendix duplo folio*, referred to this plant by Linneus, is not a *Pothos*, but *Flagellaria repens*.

2. This is alſo paraſitical, and in habit reſembles the Aloe. It has no ſtem. Leaves wedge-lanceolate, acuminate, ſmooth, on a ſhort petiole, coriaceous, ſomewhat rigid, numerous, radical, a foot and half or more in length. Scape axillary, round, a foot long. In Martinico they call it *Queue de rat* from the form of the flowering ſpadix [a].

Native of South America, and the iſlands of the Weſt Indies. Jacquin obſerved it in the vaſt mountain woods of Martinico.

3. This was found by Plumier in South America.

4. Found in the iſland of St. Thomas by Plumier [a].

5. This is a ſubparaſitical plant, with thick long filiform ſimple ſmooth whitiſh roots. Stems ſeveral, heaped, two or three feet long, rooting, ſimple, thickiſh, round, ſtiff, knobbed, ſheathed, leafy, ſmooth. Sheaths at the knots of the ſtem or at the inſertion of the petioles, ſurrounding the ſtem, of a netted contexture, ferruginous. Leaves ſcattered, alternate, acuminate, convex, dotted but not perforated, membranaceous. Petioles thickiſh, middling, round, channelled above, ſmooth, ſheathing at the baſe. Scapes from the boſom of and ſcarce longer than the petioles, erect, round, ſmooth, ſolitary, three-cornered. Spathe ovate, concave, entire, ſhorter by half than the ſpadix, ſpreading. Spadix half an inch long, cylindrical, green. What Linneus calls the corolla conſiſts of four triangular valves retuſe at the tip, not to be diſtinguiſhed but in the berry-bearing ſpadix. Filaments four, like petals, membranaceous, whitiſh, permanent, within the valves, cloſing up the germ, concealed ſo that the anthers appear to ſit on the ſtigma. Anthers twin, with one-valved lobes. Germ roundiſh. Stigma biſid. Berry rolled up in the valves at the baſe, pellucid, violet-coloured, four-ſeeded. Seeds oblong, remotely diſpoſed in a ſquare, white.

Native of Jamaica, on the higheſt mountains, at the roots and on the trunks of trees [b].

Browne obſerved it in the woods above St. Ann's bay; and ſays, that it ſticks pretty cloſe to the trunk of whatever tree it grows upon, but ſeldom runs above two or three feet in length.

Aublet found it in Guiana.

6. This is a paraſitic ſpecies, growing on trees in hilly woods in South America. The whole plant is ſmooth; the roots numerous, cylindric, long, of the thickneſs of a quill, outwardly whitiſh, inwardly green: the radical leaves are ſeveral, oblong-lanceolate, pointed, perfectly entire, without veins, coriaceous, firm, upright, of a bright green, a little thickened at the edges, owing to the margin being a little reflected: on the under part, if viewed with a glaſs, they appear thickly ſcattered with whitiſh points; and their length is from about a foot and half to two feet and a half: the midrib is extremely thick, often equalling the thickneſs of a finger at the lower part, and protuberating on both ſurfaces: the footſtalk is a finger thick and three or four inches long; flat above; round or a little ſubangulated beneath: the ſtipules are lanced, ſharp, upright, firm, and three inches long: the ſcapes ſeveral, ſubcylindric, horizontally ſpreading, and from one to two feet long. The ſpathe is lanceolate, and of the length of the ſpadix, ſharp, univalvé, flat, hanging, green, but ſoon growing brown, and afterwards withering: the ſpadix aſcendent, round, thicker than a quill, and three or four inches long; the whole being very thickly and unequally covered with the fructifications, which are hermaphrodite and tetragonal: the petals pale at the baſe, and browniſh at the top: the filaments white; anthers yellow: germ pale green with the top ſpotted with brown [c].

7. This very much reſembles the next ſpecies, but yet it is entirely diſtinct from it, by having the lobes of the leaves imbricate, the leaves much ſmaller, and the ſpadix much ſhorter [d].

Native of South America.

8. This is a ſubparaſitical, ſtemleſs plant. Root knobbed, unequal, thick, fleſhy, a foot long, ferruginous-mealy on the outſide, of a ſpongy red ſubſtance within, putting forth very long filiform fibres. Leaves all radical, very large, from one to two feet in length, membranaceous, hanging down, veined, nerved behind, ſmooth on both ſides, ſhining, green. Petioles long, round, channelled, ſmooth. Peduncles or ſcapes longer than the petioles, round, ſmooth. Spathe lanceolate, attenuated, membranaceous, coloured. Spadix a foot long and more, round, thick, nodding, covered with minute florets in cluſters, ſeparated by lines cutting each other in ſquares. Flowers blue [e].

Native of the Weſt Indies and Guiana.

9. Plant ſix feet high and ſtemleſs. Leaves large and pinnatifid; on round long erect petioles. Scape naked, almoſt equal to the leaves, quite ſimple. Leaves, petioles and ſcapes all beſet with many crooked ſhort ſcattered prickles [f].

Loureiro ſeparates it from *Pothos*, and names it *Laſia*, from Λαιος, *horridus*, on account of its pricklineſs. Willdenow remarks that his deſcription and Rumphius's figure do not agree.

Native of the Eaſt Indies and Cochinchina.

10. This was found by Plumier in South America. It is paraſitic on the trunks of trees: the leaves are often more than three feet long, with a footſtalk near four feet long: the leaves are divided in the manner of thoſe of the Vitex Agnus caſtus; they are as thick as ſtrong parchment, ſmooth, and of a deep green above; ſomewhat lighter beneath: the diviſions of the leaf do not reach to the footſtalk, and each is marked by a ſtrong nerve or midrib. The fructifications are born on ſpikes of more than a foot long.

11. This is paraſitic on trees in the hotter parts of South America. Profeſſor Jacquin deſcribes it as flouriſhing extremely well in the ſtove, and flowering through the whole ſummer and autumn, but not perfecting its fruit. It is a ſmooth plant, with large deep green leaves, riſing from channelled footſtalks: they are of a ſubcoriaceous ſubſtance, and marked with lateral veins: the ſpathe is ſeſſile, ſuberect, green, flat, and leaf-like, but ſmaller than the leaves. The ſpathe is finger-ſhaped, upright, and about two inches long; and very thickly covered with flowers: the petals are white with green tips [g].

12. Native of woods in Cayenne, where it was diſcovered by Aublet. It differs from the former in having ovate-acuminate leaflets, which are always five in number. The corolla is hexapetalous, and the ſtamens ſix. The plant riſes with ſeveral ſtems, which are voluble and ſcandent, and are ſcattered over the trunks of trees; rooting at the knots or joints. The leaves are alternate and ſmooth: the flowers numerous, and thickly ſet on the ſpadix [h].

13. This has already been deſcribed under *Dracontium fœtidum*, which ſee.

Mr. Miller was favoured with it by Mr. Peter Collinſon, (before 1759) who procured it from North America. It flowered two years in the garden at Chelſea, but in a very dry ſeaſon decayed. The flowers came up before there was any appearance of leaves, the ſpathe was large, and the ſpadix ſhort and blunt, the florets were ranged in a ſort of chequer-work diagonal to the ſpadix.

[POUTERIA. See *Labatia*.]

PRASIUM. (Πρασιον *of Dioſcorides.* Πρασιαι *are beds in gardens.* Πρασον *or* Πρασιον *is the leek; and* Πρασιον,

[a] Linn. ſyſt. [b] Linn. ſpec. [a] Jacquin. [b] Linn. ſpec. [b] Swartz, deſcr.

[a] Jacquin, collect. [b] Willdenow. [c] Swartz, deſcr. [d] Loureiro. [e] Jacquin. [f] Aublet.

is an herb resembling Horehound or Marjoram in Dioscorides and Pliny.)

Lin. gen. n. 737. *Reich. n.* 795. *Schreb. n.* 992. *Gærtn. t.* 66. *Juss.* 117.

Class. 14. 1. Didynamia Gymnospermia.

Nat. order of *Verticillatæ*. *Labiatæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, campanulate-turbinate, erect, bilabiate: *upper lip* wider, semitrifid, acute; *lower lip* a little smaller, two-parted.

COR. one-petalled, ringent: *upper lip* erect, ovate, obsoletely emarginate, concave: *lower lip* wider, trifid, reflex; the middle segment larger.

STAM. *Filaments* four, awl-shaped, pressed to the upper lip, spreading, shorter than the upper lip: two shorter than the two others. *Anthers* oblong, lateral.

PIST. *Germ* quadrifid. *Style* filiform, length and situation of the stamens. *Stigma* bifid, acute, with one segment shorter.

PER. *Berries* four, at the bottom of the calyx, roundish, one-celled.

SEEDS solitary, roundish.

OBS. *The seeds themselves, being clothed with a berried epidermis, have the nature of a berry. Hence we have a tetragymnospermous baccíferous plant, by which mark it is distinguished from all other plants of this order.*

ESSENTIAL CHARACTER.

Berries four, one-seeded.

SPECIES.

1. Prasium majus. *Great Spanish Hedge-nettle.*
   Lin. spec. 838. *Reich.* 3. 103. *hort. cliff.* 309. *upsal.* 173. *Gærtn. fruct.* 1. 321. *Desfont. atlant.* 2. 33. *Kniph. cent.* 4. *n.* 66. *Sabb. hort.* 3. *t.* 37.

   Melissa fruticosa sicula, calyce amplo patulo. *Raii hist.* 568.
   Leaves ovate with a double notch on each side.

DESCRIPTIONS, *&c.*

1. This rises with a shrubby stalk two feet high, covered with a whitish bark, and divides into many branches. The flowers come out from the bosom of the leaves in whorls round the stalks; they are white, and have large permanent calyxes, cut into five points.

[The branches are declining; the leaves are the size of those of Baum, cordate, smooth, blunt, petioled. Whorls of flowers approximating. Calyx large goblet-shaped, with ovate acuminate teeth. Corolla spreading: upper lip entire, obtuse, convex; lower three-lobed[1]. Seeds four, like berries, subglobular, convex on one side, angular on the other, turning black when ripe: they have three integuments, the outer fleshy thin and soft, the middle crustaceous and brittle, the inner membranaceous and dry[2]. Desfontaines remarks, that some of the seeds are usually abortive.

Native of Spain, Italy, Sicily, Tunis and Algiers, in hedges. It flowers here from june to august.—Cultivated by Mr. Miller in 1729[3].]

2. This has a shrubby stalk like the former, but rises a little higher; the bark is whiter, the leaves are shorter and ovate, and of a lucid green. The flowers are somewhat larger, and are frequently marked with a few purple spots.—Native of Sicily.

[1] Desfontaines. [2] Gærtner. [3] Hort. kew.

[Linneus doubts whether this be sufficiently distinct from the preceding to make it a species, or only a variety. Retzius asserts positively, that there is no character to distinguish them.]

PROPAGATION AND CULTURE.

These plants may be propagated either by cuttings, or from the seeds; if they are propagated by cuttings, they should be planted on a shady border towards the end of april; but the cuttings should not be taken from such plants as have been drawn weak, but rather from those which have been exposed to the open air, whose shoots are short and strong; and if a joint of the former year's wood is cut to each of them, they will more certainly succeed. These cuttings may remain in the same border till they are well rooted, when they may be transplanted into the places where they are to remain, or into pots, that they may be sheltered in winter under a common frame, where they may have as much free air as possible in dry weather, but only require to be screened from hard frost. If they are propagated by seeds (which the plants produce in plenty every year) they should be sown on a bed of light earth in april; and in may the plants will come up, when they require no other care but that of keeping them clean from weeds; and in the autumn following, they may be transplanted in the same manner as before directed for those raised from cuttings, and may be afterwards treated more hardily, as they acquire strength.

A plant or two of each of these species may be allowed to have a place where there are collections of the different sorts of ever-green shrubs, for the sake of variety; especially where the different sorts of Cistus, Phlomis, Tree-wormwood, and Medicago, are admitted, because these are equally hardy; and when a severe winter happens, which destroys the one, the others are sure of the same fate; but in mild winters they will live abroad, especially if they are planted in a dry rubbishy soil, and have a sheltered situation; but in rich wet ground, the plants growing vigorous in summer, are liable to injury from the early frosts in autumn.

[PREMNA. (*From πρεμνον, stirps, truncus.*)

Lin. gen. Reich. n. 823. *Schreb. n.* 1025. *Gærtn. t.* 56. *Juss.* 107.

16. Prenanthes humilis. *Dwarf Prenanthes.*
Lin. ſyſt. 715. *Thunb. jap.* 302.
Leaves lyrate, lobes obtuſe, ſtem almoſt naked, flowers terminating in twos or threes.

17. Prenanthes multiflora. *Many-flowered Prenanthes.*
Lin. ſyſt. 715. *Thunb. jap.* 303.
Leaves petioled runcinate, lobes acute toothed, panicle faſtigiate diffuſed.

18. Prenanthes lyrata. *Lyrate-leaved Prenanthes.*
Lin. ſyſt. 715. *Thunb. jap.* 303.
Leaves runcinate-lyrate toothed, panicle contracted.

19. Prenanthes ſquarroſa.
Lin. ſyſt. 715. *Thunb. jap.* 303.
Leaves ſeſſile runcinate, ſegments recurved toothed.

DESCRIPTIONS, *&c.*

1. Root perennial, oblong, twiſted, oblique, creeping, and here and there putting forth other ſtraight roots. Stems erect, from two to three feet high and more, round, ſimple, leafy, ſlender. Leaves alternate, embracing, ſeſſile, bright green. From the axil of each leaf iſſues a panicle of flowers; the peduncles of which are one or two-flowered. Each flower has five florets, which are purple, as in the fourth ſpecies, which this reſembles, but the leaves are narrower, and rarely toothed at the baſe. Native of the South of Europe, on mountains[*].

2. The whole plant is ſmooth. Root-leaves attenuated at bottom, ſubpetioled, toothed, a hand in length: ſtem-leaves, the lower ones ſeſſile, enſiform, toothletted and entire, the upper ones lanceolate, entire, an inch long. Flowers panicled, yellow. Peduncles directed one way, drooping, capillary, naked. Native of China and Japan[†].

3. Root biennial or perennial, oblong, pale yellow. Stems decumbent, from a foot or eighteen inches to two feet or even three feet in length, hard, round, whitiſh, viſcid, ſtriated, branched, covered by a portion of the leaf which is faſtened along it. Root-leaves pinnatifid, and reſembling thoſe of *Lactuca perennis*: ſtem-leaves lanceolate, oblong, entire, viſcid. Flowers axillary, by threes, almoſt ſeſſile: calyx cylindrical, a little oval, ſmooth, compoſed of five large equal ſcales, and of four that are ſmaller, unequal, and membranaceous at the edge next the baſe: florets five yellow. Seeds oblong, flatted below; terminated by a ſmall ſeſſile egret. It is not eaſy to diſtinguiſh this plant at firſt ſight from *Lactuca ſaligna*, but the ſtem partly covered by the leaves, and the ſeſſile egret ſuffice for that purpoſe[‡].

Parkinſon calls it Galen's Gum Succory; and Ray, Wild Lettuce with booted ſtalks, which is a tranſlation of Columna's Greek name.

Native of the South of Europe; Ray gathered it about Montpelier, and near Meſſina in Sicily, on rocky hills. It flowers in june and july.

Allioni has another ſpecies, which he names *ramoſiſſima* (*n.* 830.) and figures in *t.* 33. *f.* 1. He ſays it approaches near to *viminea*, but that the latter is three times as high, and has much fewer branches; that the root-leaves are ſinuate-pinnatifid, with the extreme pinnule triangular, and that they are firm, not truly runcinate: whereas in *ramoſiſſima* the root-leaves are more tender, truly runcinate, not pinnatifid to the midrib, but only cut to the middle of the leaf, with the extreme pinnule linear-lanceolate. In *P. viminea* there are two, three or even four ſeſſile flowers: the florets are wide, marked with lines, yellow, five-toothed, the length of the calyx; of which the five inner long ſcales are nearly equal, the five outer are unequal. The ſtem-leaves are pinnatifid, and have hairs here and there at the midrib.—The leaves in *P. ramoſiſſima* are quite ſmooth, and not villoſe underneath, glaucous, even, tender, with a white rib: the ſtem is branched from the bottom; the branches are erect and ſimple; the leaves on the branches alſo are decurrent, lanceolate, and quite entire; there are two or three flowers from the axils of the leaves, with the florets twice as long as the calyx, which has all the ſcales imbricate and unequal; the florets are five-toothed, but narrower than in *viminea*.

Native of the county of Nice on the ſandy coaſt; and near Caſtiglia d'Ivrea. It is biennial and annual.

4. Root perennial, tranſverſe, long, woody, fibrous. Stem erect, three, four or five feet high, much branched towards the top, terminated by nodding panicles of flowers, placed on naked axillary peduncles longer than the leaves. Leaves even, bright green above, glaucous underneath; ſtem-leaves acuminate, embracing, hooked, ſpreading, lanceolate, ſharply toothed. Calyx green, cylindrical, with unequal ſcales in two rows, four or five in the inner, three or four in the outer. Florets four or five violet-purple, five-toothed. Seeds oblong, acute, with a ſeſſile egret. Anthers reddiſh. Filaments white. Style purpliſh[†].

Villars remarks that this plant varies much; that the ſtems are even, firm, and cylindrical, very much branched at the end, and frequently at the axils of the leaves; that the ſtem-leaves are half embracing, and then are lengthened out and wider more or leſs towards the middle and end; that the whole plant is ſmooth; that the flowers come out on branches and peduncles divaricating almoſt at right angles, and very much ſubdivided; and that the purpliſh blue florets are five in number, almoſt always rolled up and oblique, and often pendant.

Receptacle very narrow, papilloſe, ſmooth. Seed oblong, attenuated below, obſoletely angular, ſtriated, pale ſtraw-colour. Pappus ſeſſile, caducous; with numerous, ſilky-white, capillary rays, ſparingly toothletted, half as long again as the ſeed[‡].

Gærtner remarks, that *Prenanthes* differs chiefly from *Chondrilla* in having a *ſeſſile* pappus. Juſſieu thinks they might make one genus. But there is no end of ſuch doubts in natural orders, which may be conſidered as one genus.]

Miller, following Caſpar Bauhin, has made two ſpecies of this, a larger and a ſmaller, one four feet, the other only a foot in height, with a more branching ſtem, and wider leaves embracing it.

[Native of Germany, Switzerland, Auſtria, the South of France and Italy. Ray found it on mounts Jura and Saleve near Geneva, and in mountain woods between Schaffhauſen and Conſtance.—It was cultivated in Britain by Mr. James Sutherland, in 1683; and flowers from july to ſeptember[‡].

5. Root perennial, ſomewhat woody, branched, pale brown, milky. The whole plant ſmooth, tender, brittle, milky. Stem from one to two or three feet in height, upright, ſimple, leafy, ſomewhat flexuoſe at top, round, glaucous, purpliſh. Root-leaves very like thoſe of the common Sow-thiſtle, darkiſh green, purple on the under ſide, on long foot-ſtalks, deeply notched, the lower ſegments few, ſomewhat oval, the terminating one ſomewhat triangular, but with five lobes, the middle one ſharp, toothed. Stem-leaves alternate, embracing, nearly ſimilar in figure; deeply notched; ſegments oppoſite, toothed, the terminating one largeſt. Panicle divaricating, flexuoſe; each flowering-branch ſubdivided into ſlender peduncles, bearing one flower, and having one minute ovate or lanceolate bracte. The outer calyx conſiſts of three ovate or lanceolate ſcales; the inner of five linear leaflets, with membranaceous edges, and commonly coloured. Florets five, in a ſingle row, lemon-coloured, ſpreading, longer than the calyx. Seeds oblong or obovate, compreſſed, furrowed, black, ſurmounted with an egret on a flat circular ſubſtance on a very ſhort ſtipe, rays ſimple, the length of the interior calyx[*].

There is a variety of it with the upper leaves undivided, deſcribed by Withering.

Native of many parts of Europe, in woods, hedges, and ſhady banks in a calcareous ſoil, and on walls; flowering from july to ſeptember. On Hampſtead-heath, and Hornſey in Middleſex. On the willows by the old ſluice at Grantcheſter near Cambridge, and

[*] Krocker, Allion. Villars. [†] Thunberg. [‡] Villars and Krocker.

[*] Krocker. [†] Gærtner. [‡] Hort. kew. [*] Woodv. Mſs. Smith. Withering.

on Chippenham-park wall. On the top of Staunton Harcourt-kitchen, and in Stokenchurch-woods, Oxfordſhire. Biſhopſgate-ſtreet, Norwich. Welwyn in Hertfordſhire. Croyden in Surry. Cleiſden in Buckinghamſhire. Weekly in Northamptonſhire. Baſford in Nottinghamſhire. Peak's-hole in Derbyſhire. —Our old authors call it *Ivy-leaved Lettuce*, or *Wall Sow-thiſtle*.]

6. The lower leaves are four or five inches long, and three broad, they are ſometimes divided into five lobes, but generally into three; they are indented a little on their edges, ſmooth, dark-green above, but pale underneath. Stems three feet high, with a few ſmall entire leaves on them: the flowers come out from the ſide of the ſtem in ſmall bunches; they are of a pale yellow colour, and appear in july. There is a variety with pale purple flowers, ariſing from the ſame ſeeds.

Native of Virginia and Canada; according to Mr. Miller, of moſt parts of North America, where it is called Dr. Witt's Rattle-ſnake root, the roots being taken for an antidote to the venom of the Rattle-ſnake. It ſeldom lives longer than two years. [It is however marked as perennial in the Kew Catalogue; where it is alſo obſerved from Plukenet, that it was cultivated in the botanic garden at Chelſea in 1696.

7. Stem panicled. Stem-leaves linear, at the ramifications only, minute: root-leaves lanceolate, petioled, naked, minutely toothed[x]. Peduncles axillary, ſlender, not ſo long as in *purpurea*. Flowers almoſt as in that, but fewer, not nodding. Panicle narrower, leſs dichotomous[y]. Native of the South of Europe.

8. Root-leaves very many, lyrate, ſmooth, reſembling thoſe of *Lapſana communis*: lower lobes alternate, blunt, connected, reflex, angular-toothed, ciliate with a few ſhort hairs; the terminating lobe is very large, blunt, gaſhed, angular-toothed, ciliate. Stem almoſt leafleſs, weak, erect, branched, ſmooth, from a foot to two feet high and more. Branches alternate, filiform, flowering. Flowers terminating, panicled, yellow. Peduncles and pedicels alternate, capillary, ſpreading. Bractes under the peduncles briſtle-ſhaped. Calyx many-leaved, erect, ſmooth; calycle very ſhort, ſmooth, with ovate acute ſcales. Native of Japan[z].

Linneus remarks, that the flowers are very numerous and very ſmall; the florets in each about fifteen; and the down longer than the calyx.

9. Native of North America. Introduced in 1778, by Mr. William Young. It flowers in july and auguſt[a].

10. Retzius is of opinion that this plant belongs rather to the genus of *Hieracium*. He thus deſcribes it. Stem creeping, rooting. Branches aſcending, leafy, ſmooth. Root-leaves on long petioles, three-parted, with the lobes oval, toothletted: ſtem-leaves on ſhort petioles, ovate, toothletted. Peduncles from one to three-flowered, ſcaly. Calyx ſimple, erect, glaucous, with linear-lanceolate leaflets, ſomewhat ſcarioſe at the edge, calycled as it were with ſmaller ſcales at the baſe. Corollas yellow, about twelve. Egret ſimple, ſeſſile. Receptacle naked. Linneus had it originally from Kamtſchatka; Bladh ſent it afterwards from China[b].

11. This is a ſhrub with roundiſh reſinous branches. Leaves approximating, petioled, a ſpan long, ſpreading and recurved; pairs of leaflets ten or twelve, very ſlender and ſmooth. Panicle large. Calyxes ſmooth. Flowers ſmall, yellow[c]. Retzius ſays that it is undoubtedly a ſpecies of *Sonchus*[d]. It was found by Maſſon on rocks in the iſland of Teneriffe[e].

12. Root annual. The whole plant ſmooth. Stem decumbent at bottom and creeping, then erect, round, ſtriated, ſimple or panicled, a ſpan high. Lower leaves aggregate, alternate, petioled, obovate-oblong, obtuſe, rolled back at the edge, a hand in length; ſtem-leaves embracing, ſomewhat toothed, an inch long. Panicles terminating, roundiſh. Flowers yellow.

13. The whole plant is tender and ſmooth. Root annual, fibrous. Stems ſeveral, weak, almoſt upright, few-flowered, a ſpan high. Root-leaves very many, petioled, obtuſe, a finger's length: ſtem-leaves few, ſeſſile. Flowers terminating, one, two or three together, yellow.

14. The whole plant is ſmooth. Stem round, ſtriated, erect, from a foot to two feet in height. Root-leaves petioled, oblong, blunt with a point, toothletted, a hand in length: ſtem-leaves embracing, ciliate-toothed at the baſe and in the middle, acute, a finger's length. Flowering branches rod-like, erect, panicled. Peduncles capillary, ſpreading, ſubumbelled.

15. The whole plant ſmooth. Stem round, ſtriated, flexuoſe-erect, purpliſh, two feet high. Branches alternate, ſpreading, like the ſtem. Leaves on the ſtem and branches half embracing, haſtate, ſubſpatulate, acute, acutely toothed, nerved, an inch long, the upper ones gradually diminiſhing. Flowers on the extreme branches and branchlets terminating, panicled, yellow. Panicle roundiſh, ſpreading little, with very ſhort peduncles.

16. Root annual, fibrous. The whole plant ſmooth. Stems radical, ſeveral, weak, decumbent or flexuoſe-erect, a hand in height. Root-leaves many, a finger's length: ſtem-leaves very few, half an inch long, all petioled; the outer lobe very large, rounded, ſomewhat toothed; the reſt minute, reflexed. Flowers ſolitary, or two or three together, yellow.

17. Root fibrous, annual. Stem branched at the bottom, erect, grooved, villoſe, ſmooth at top, panicled, two feet high. Root-leaves ſubpetioled, ſmooth, a ſpan long; lobes difform, angular, briſtly-toothed: ſtem-leaves gradually leſs. Peduncles flexuoſe: pedicels capillary.

18. Root fibrous, annual. Stem round, ſtriated, villoſe at bottom, gradually attenuated at top, ſmooth, weak, erect, ſeldom branched. Root-leaves very many: ſtem-leaves alternate, remote: all petioled, ſmooth above, villoſe-ſcabrous underneath, a finger's length, gradually leſs: lobes angular, toothed; the terminating lobe larger. Flowers terminating, panicled, yellow. Panicle roundiſh, little ſpreading, often drooping.

19. Stem fleſhy, herbaceous, round, ſtriated, ſmooth, erect, ſimple, two feet high. Leaves alternate, attenuated below; pinnas recurved, toothed at the upper margin, glaucous underneath, acuminate, a ſpan long. Flowers terminating, panicled. Panicle oblong, thyrſoid.—All theſe were found by Thunberg in Japan[f].]

PROPAGATION AND CULTURE.

Theſe plants are ſeldom admitted into gardens; but the ſeeds may be ſown ſoon after they are ripe in a ſheltered ſituation, and when the plants come up, they require no other care but to be kept clean from weeds.

Lin. ſpec. ed. Willd. 806. *Allion. pedem. n.* 338. *t.* 5. *f.* 1.
Leaves ovate quite entire villoſe-viſcid, umbel erect, corollas ſalver-form.

20. Primula ſibirica. *Siberian Primroſe.*
Lin. ſpec. ed. Willd. 806. *Jacqu. miſc.* 1. 161. *Gmel. ſib.* 4. 83. *t.* 46. *f.* 1.
Leaves quite entire ovate on long petioles, umbel few-flowered nodding, corolla ſalver-form.

DESCRIPTIONS, *&c.*

1. Leaves radical, lanceolate ovate, ending in a flat petiole double the length of the leaves, unequally ſerrate towards the top, quite entire at bottom, acute, veined, mealy underneath, two inches long. Scape erect, round, the ſize of a gooſe quill, a foot high and more. Towards the top are two or three remote whorls, the lower ſix-flowered, the upper ones many-flowered. Bractes under the lower whorls lanceolate, ſerrate at top, an inch long; in the terminating whorl lanceolate-ſubulate, quite entire, all mealy underneath. Pedicels the length of the bractes, roundiſh, ſlender, mealy. Perianth one-leafed, bell-ſhaped, abbreviated, mealy, deeply five-cleft: ſegments ovate-lanceolate, acuminate. Tube of the corolla cylindrical, club-ſhaped, mealy at the baſe, an inch long[g].—Native of mount Kurma, by rivulets[h].

2. The common Primroſe has a perennial root, growing obliquely, appearing as if bit off at the end, beſet with thick reddiſh ſcales which are the remains of paſt leaves, ſending down numerous very long round whitiſh fibres; it has a ſingular ſmell, ſomewhat like that of Aniſe. Leaves obovate-oblong, about a hand's breadth in length, nearly upright, tapering to the baſe, blunt, veiny, wrinkled, ſmooth above, hirſute beneath, rolled back at the edge when young, ſlightly waved, unequally notched, the midrib whitiſh, terminating in a footſtalk of a reddiſh colour, channelled on one ſide and keeled on the other. Scapes or peduncles numerous, the length of the leaves, upright, round, hirſute, pale green, having awl-ſhaped bractes at the baſe, after the flowering is over bending back. Flowers upright, large, ſweet-ſcented. Corolla of a pale ſulphur colour; each of the five cleſts obcordate, and marked at the baſe with a ſpot of a much deeper yellow; the mouth has a faint rim round it. Filaments either within the tube or at the mouth of the corolla. Anthers oblong, ſomewhat three-cornered, converging. Germ ſuperior, ſmooth. Style uſually ſhorter than the tube[i]. Capſule ovate, narrower upwards, ſmooth, opening at top with ten ſhort recurved teeth. Receptacle globular, pedicelled, excavated, looſe. Seeds about thirty, very ſlightly convex on one ſide, and obſoletely angular on the other, ſhagreened with raiſed dots, and of a blackiſh colour; the navel in the middle of the belly[k].

Native of moſt parts of Europe, in woods, coppices, hedge-rows and ſheltered lanes, particularly in a clayey ſoil; flowering in march and april with the wood Anemone.

The leaves and root of Primroſe ſeem to partake in ſome degree of the nature of thoſe of *Aſarum*, acting as ſtrong errhines or ſternutatories, when ſnuffed up the noſe; the roots act as emetics. Gerarde reports, as from the experience of a ſkilful practitioner, that a drachm and half of the powder of the dried roots, taken up in autumn, purges by vomit very forcibly, but ſafely[l].

The flower of the wild Primroſe, as every body knows, is of a pale brimſtone colour; but in ſome parts of the country it is found of a purple hue. Its varieties are very numerous, partly wild and partly obtained from culture.

Parkinſon enumerates the following:

1. The ſingle white. 2. The ſingle green. 3. The ſingle green and white. 4. The double green. 5. Maſter Heſket's double Primroſe; which Gerarde ſays was found in Clapdale-wood near Settle in Yorkſhire, by a learned gentleman of Lancaſhire, called maſter Thomas Heſketh, a diligent ſearcher of ſimples. 6. The ordinary double. 7. The ſmall double.

Gerarde, beſides the common, figures the double white and the green Primroſe. Johnſon has added a figure of Heſketh's Primroſe; Mr. Curtis ſays he has not met with this curious variety in any of the collections about London. The following are the moſt ſtriking varieties which he has cultivated:

1. The ſingle white. 2. The paper white. 3. The red or purple of various ſhades. 4. The hoſe in hoſe. 5. The double yellow. 6. The deep velvet red. 7. The pale red or fleſh-coloured. 8. The dingy purple or Scotch Primroſe, which grows wild in Scotland, and is figured in the Flora Ruſtica. The double yellow is figured by Parkinſon and Beſler; and the double pink or lilac, a beautiful and much admired variety, is figured in Curtis's magazine. But the varieties of the Primroſe, ſo much eſteemed by florifts under the name of POLYANTHUS, are boundleſs.

A fine flower of this ſort ſhould poſſeſs a graceful elegance of form, a richneſs of colouring, and a perfect ſymmetry of parts. Its properties are in moſt

[g] Vahl. [h] Forſk. [i] Curtis, Smith. [k] Gærtner. [l] Lewis.

reſpects

reſpects the ſame as thoſe of the Auricula, as to the ſtem or ſcape, peduncles or flower-ſtalks, and the formation of the umbel, bunch or thyrſe, corruptly called the truſs.

The tube of the corolla above the calyx ſhould be ſhort, well filled at the mouth with the anthers, and terminate fluted rather above the eye.

The eye ſhould be round, of a bright clear yellow, and diſtinct from the ground colour.

The ground-colour is moſt admired when ſhaded with a light and dark rich crimſon, reſembling velvet, with one mark or ſtripe in the centre of each diviſion of the border, bold and diſtinct from the edging down to the eye, where it ſhould terminate in a fine point.

The petal (technically the pips) ſhould be large, quite flat, and perfectly circular, excepting the ſmall indentures between each diviſion, which ſeparate it into five (ſometimes ſix) heart-like ſegments.

The edging ſhould reſemble a bright gold lace, bold, clear and diſtinct, and ſo nearly of the ſame colour as the eye and ſtripes as ſcarcely to be diſtinguiſhed [n].

3. The Oxlip has the leaves contracted towards the middle almoſt as in the Cowſlip. Scapes few, erect, longer than the leaves, many-flowered. Flowers umbelled, pedicelled, the outer ones generally nodding; like thoſe of the Primroſe in form and colour, but ſmaller [o]. From this it is evidently diſtinguiſhed by its many-flowered ſcape; as it is from the Cowſlip by the flat border of the corolla. If it be a variety, it is rather of the former than the latter. Dr. Smith rather inclines to think that the Oxlip is a hybrid production or mule, from a Primroſe impregnated by a Cowſlip; its habit, the contraction towards the middle of the leaf, and the umbellate flower-ſtalk indicating (according to Linneus's ingenious idea) the father, whilſt in the corolla, its form, colour and ſcent, it moſt reſembles the mother [p]. To many this will ſeem fanciful; and to others, ſince the Oxlip produces fertile ſeed, it will appear doubtful.

Oxlip is found in woods, thickets, hedges, and ſometimes in paſtures, but it is by no means ſo common as the Primroſe and Cowſlip. Calcareous thickets and hedges in Cambridgeſhire; clayey paſtures in Suffolk; Headington-wick copſe, Stow-wood, and South Leigh in Oxfordſhire; common in ſome parts of Bedfordſhire; about Stilland and Shillingley-park in Suſſex; near Wray-houſe, Sir James Wright's, adjoining to the river Rhodon, in Eſſex; high paſtures near Little Wenlock in Shropſhire. It flowers in april and may.

4. The Cowſlip has a root like that of the Primroſe, but ſmelling more powerfully of Aniſe. Leaves obovate-oblong, contracted ſuddenly towards the middle; or rather ovate with the petioled winged; ſhorter than thoſe of the Primroſe by nearly one half, fuller at the edge, which is ſomewhat folded as well as notched, ſtronger, of a deeper green, not running ſo taper at the baſe, covered on the under ſide with ſofter and ſhorter hair; the petioles ſmoother, whitiſh with ſcarcely any red in them. Scapes few, three or four times longer than the leaves, round, upright, pale, villoſe. Involucre at the baſe of the umbel, ſurrounding the peduncles, conſiſting of many, very ſmall, concave, pale, acuminate leaflets. Flowers in an umbel, unequally pedicelled, hanging down, generally to one ſide, full yellow with an orange-coloured blotch at the baſe of each ſegment, contracted about the middle of the tube, where the ſtamens are inſerted, paler underneath, very fragrant. Calyx five-cornered, inflated, ſitting looſely about the tube of the corolla, villoſe; ſegments ovate, acute. Tube of the corolla a little longer than the calyx: border very ſhort, concave; ſegments emarginate; mouth ſimple, without any crown [q].

Native of Europe both in moiſt and upland paſtures, and on the borders of fields, in a clayey or loamy ſoil, preferring an open ſituation, and flowering in april and may. It is ſo common in many paſtures as to be an injurious weed, though reſpected for its elegance and uſe.

The leaves are ſometimes eaten as a pot-herb, and in ſalads. They are recommended for feeding ſilk-worms, and may ſerve the ſame purpoſe as ſeedling Lettuces, for the young worms, before the Mulberry leaves make their appearance. But the leaves of this tree only can feed the worms to maturity, to any good purpoſe.

The fragrant flowers make a pleaſant wine, approaching in flavour to the Muſcadel wines of the South of France. It is commonly ſuppoſed to poſſeſs a ſomniferous quality.

Theſe flowers have a roughiſh bitteriſh taſte, which they impart with their agreeable odour and a yellow tincture, both to water and ſpirit. Vinous liquors impregnated with them by maceration or fermentation, and ſtrong infuſions of them drank as tea, are ſuppoſed to be mildly corroborant, antiſpaſmodic and anodyne. An infuſion of three pounds of the freſh flowers in five pints of boiling water, is made into a ſyrup of a fine yellow colour, agreeably impregnated with the flavour of the Cowſlips [r].

Theſe plants are here deſcribed as three diſtinct ſpecies. Linneus, beginning his career at a time when varieties had attracted undue notice, perhaps went too far in avoiding a multiplication of ſpecies; in the preſent caſe at leaſt few botaniſts have followed him in conſidering the Primroſe, Oxlip and Cowſlip as one ſpecies. Had only the firſt and laſt exiſted in their pure natural ſtate, little doubt would probably have occurred of their being diſtinct ſpecies; but the Oxlip partakes ſo much of the nature of both, that it creates a ſuſpicion of all the three having been originally one, as Retzius (obſ. 2. p. 10.) ſtill affirms them to be, eſpecially when we become acquainted with their great mutability, and view a number of intermediate links connecting them ſtill more intimately. Linneus aſſerts, that the peduncles in the common wild Primroſe ſpring from a ſcape, which being ſo ſhort as to be concealed among the leaves, has not been obſerved; this latent ſcape has never occurred to me in the wild Primroſe; Mr. Curtis ſays he has found it in a few plants. I have however met with it, puſhing up a tall ſcape, which ſuſtained ſeveral flowers differing in no reſpect from the ordinary ſort except in this circumſtance. This forms a connecting link between the Primroſe and Oxlip. The Scotch Primroſe, figured in *Flora Ruſtica*, t. 62. is another link in the chain, and is a ſtep taken by nature towards the admired *Polyanthus*, of which culture has produced a variety almoſt infinite. Mr. Curtis informs us that wild Primroſes introduced into Dr. Buxton's garden, at Maize-hill near Greenwich, produced flowers both with and without a ſcape, and indeed became, colour excepted, perfect Polyanthuſes: and Willdenow ſays he has ſeen one-flowered peduncles and many-flowered ſcapes from the ſame root. I have not unfrequently found the common Primroſe wild, of a dingy purple colour, and the Scotch Primroſe ſhows a tendency in colour as well as plurality to the Polyanthus. Mr. Curtis relates, that in his garden the white hoſe in hoſe Primroſe produces early in the ſpring flowers on peduncles, and afterwards on a ſcape, or in a thyrſe; and that the Cowſlip and Oxlip ſometimes produce flowers on peduncles as well as on a ſcape. In other reſpects the Cowſlip does not ſeem to vary ſo much as the Primroſe, except in colour. I have ſometimes found the wild Cowſlip with the flowers of a fine red; in gardens this is not uncommon. Gerarde and Parkinſon figure a variety with double flowers, which ſeems now to be loſt; and Parkinſon enumerates ſeveral others in his Paradiſus: Mr. Curtis had a hoſe in hoſe variety with yellow and another with deep ſcarlet flowers. But what does all this prove, ſays Mr. Curtis, except that theſe plants, like many others, are ſubject to the ſportings of nature? May we not ſay rather, that theſe variations

[n] Maddock's Floriſt's Directory. p. 219.
[o] Smith. [p] Id. engl. bot. 543.
[q] Curtis, Smith, Withering, Lyons MS. in Relh.
[r] With. Engl. bot. Curtis, Lewis.

might well give occaſion to Linneus to conſider them all as one original ſpecies? though ſince they have ſome permanent diſtinctions, (which are given in the ſpecific characters) we cannot err in taking them for two diſtinct ſpecies at leaſt. Beſides the ſtriking character, ſays Mr. Curtis, drawn from the inflorescence, to ſay nothing of the leaves, how different is the corolla in ſize and ſhape, and how very different is the calyx? In their place of growth, and time of flowering there is a material difference, the Primroſe loving ſhade and ſhelter, and flowering from march to may with the Wood Anemone, and being much diſpoſed to flower again in autumn and even during winter, if the weather be not ſevere: the Cowſlip affecting open paſtures, flowering in may with the early ſpotted Orchis, and not manifeſting any diſpoſition to flower a ſecond time towards the cloſe of the year. Dr. Withering remarks, that the leaf-ſtalks of the Primroſe, when fully grown, are longer than the leaves, in the Oxlip ſhorter, in the Cowſlip often longer than the leaves.

The above diſtinctions are either inſufficient or not to be depended upon to furniſh ſpecific differences. Even the inflorescence is not conſtant; the corolla of the Oxlip is of a middle ſize between the other two; the place of growth is different, but yet the Cowſlip is ſometimes found under hedges; april is commonly aſſigned as the month of flowering for all, but the Primroſe appears in march and the Cowſlip in april. This ſpring (1800) the woods were covered with Primroſes in full blow on the 24th of march, and a few days after, I ſaw a ſingle bloſſom of the Cowſlip beginning to expand under a warm hedge. I have Cowſlips in my garden, that conſtantly blow a ſecond time in mild winters, during the months of november and december.

Linneus having united theſe plants in one ſpecies, had no difficulty in giving it the name of *veris*; but for thoſe who conſider them as three ſpecies, it is not ſo eaſy. *Acaulis* may tend to miſlead novices at leaſt, *veris* is too general, we have therefore applied the epithet *vulgaris* to the Primroſe, following Hudſon, Withering, Relhan and Smith. For the Oxlip we ſhould have preferred *inodora*, had it not been ſaid that the flowers are ſo far from inodorous, that they have a very grateful ſmell. *Elatior* may be a proper epithet for the Oxlip when it is compared with the Primroſe; but by no means in compariſon with the Cowſlip, which has a ſtill taller ſcape. Shakſpeare adverts to this in his beautiful deſcription of the Cowſlip in his Midſummer Night's Dream, wherein he makes it ſubſervient to the Queen of the Fairies—

"The Cowſlips tall her penſioners be."

In alluſion to the inſtitution of tall military courtiers by Queen Elizabeth, called *Penſioners*. The epithet *veris* is improperly applied to the Cowſlip, which flowers later than the Primroſe. *Officinalis* is more proper, the Cowſlip having been moſt uſed in medicine, though both that and the Primroſe are neglected in modern practice. After all, I confeſs myſelf not very well ſatisfied with the trivial names.

5. Root perennial, ſomewhat præmorſe, with numerous, long, perpendicular fibres, and ſweet-ſcented. Leaves obovate-lanceolate, bright green, ſmooth and even, thickiſh, here and there turned back on the edges; underneath veined and powdered with white meal. Scape a hand's breadth or ſpan in height, far exceeding the leaves, round, upright, ſtiff and ſtraight, of a pale green colour and mealy. Flowers ſweet-ſcented, in an upright umbel, having at its baſe a many-leaved involucre, each leaflet of which is awl-ſhaped, and placed at the baſe of each peduncle. Segments of the calyx upright, a little blunt, converging a little at their tips, of a dull green colour and mealy. Tube of the corolla longer than the calyx, contracted in the middle, but the neck ſomewhat enlarged, yellowiſh; ſmooth; the mouth open and yellow: border ſmall, flat, purple, pale underneath; ſegments linear-obcordate. Capſule twice the length of the calyx, brown, with the mouth five-toothed. Seeds brown[1].

This elegant plant is a native of many parts of Europe, eſpecially the moſt northern, and alſo of Siberia: with us it is found in Yorkſhire and Weſtmoreland in wet or boggy paſtures or by the ſide of rills, flowering in july and auguſt.

The flowers vary with different ſhades of purple, and they have been found entirely white; in point of ſize the plant is alſo ſubject to much variation; in a bog in Skirrith-wood near Ingleton, Mr. Curtis obſerved it a foot and half in height: in the cultivated plant he has ſeen it have a tendency to be viviparous, to produce one or more tufts of leaves among the flowers of the umbel. In its wild ſtate it ſeeds readily, and frequently when cultivated. Towards the end of ſeptember the outer leaves fade, and the heart of the plant forms itſelf into a knob or button, a kind of hybernacle: in the ſpring it, expands, and the leaves then appear wholly white and mealy; the corolla continues to envelope the germ till it has almoſt arrived at maturity; forming a ſort of calyptre to it[2].

In habit this ſpecies approaches moſt nearly to *Androſace* and *Aretia*. In thoſe genera however the tube of the corolla is oval, not cylindrical, and its orifice is more or leſs cloſed with glands; whereas in all the Primulas that part is open, and only ſlightly crenated. Nevertheleſs theſe three genera, and even *Cortuſa*, might perhaps be united without any great violence to nature[3].

6. This bears a great affinity to *P. farinoſa*, but the leaves differ in form, colour and mode of growth; when fully grown they are twice the length of thoſe of the other: they are not mealy, the under ſide being as green as the upper, and they have a greater tendency to grow upright. The ſcape is ſhorter and thicker. The flowers form a ſimilar umbel, but each is ſmaller than in *farinoſa*, and in point of colour much leſs brilliant. Upon the whole, though ſuperior in ſize, it is inferior to that in beauty. It flowers early in may. The original place of growth is not known.

Introduced by Meſſ. Grimwood and co. nurſerymen at Kenſington, about the year 1796. They had it from France, by Mr. Williams, nurſeryman near Paris[4].

7. In the wrinkled appearance of its foliage this approaches the common Primroſe, whilſt in its inflorescence, the colour of its flowers, and ſolitary ſcape, which riſes to an unuſual height, it bears an affinity to the *farinoſa*. In the winter it loſes the leaves entirely, and forms a ſort of bulbous hybernacle under ground; this circumſtance is the more neceſſary to be known, as it ſubjects the plant to be thrown away as dead. It flowers in june and july; and is a native of Siberia[5].

Linneus remarks, that it has the leaves of *Cortuſa*, with the flowers of *Aretia Vitaliana*.

Introduced by Meſſ. Lee and Kennedy, nurſerymen at Hammerſmith, in 1798 or 1799.

8. Leaves fleſhy but hirſute, in the ſmaller variety petioled, rhomboid, toothed on the two anterior ſides. Scape an inch high, ſuſtaining one or two flowers. Bractes ovate and lanceolate. Flower equal to the whole ſtem or leaf, purple, with the ſegments cordate, longer, gaſhed, with a pale eye. Calyx not mealy, hirſute, bell-ſhaped, blunt, half the length of the tube.

The greater variety, which Cluſius has figured, has ſcapes half a foot high, and as many as ſeven flowers on a ſingle ſcape: the leaves are much larger, petioled, rhomboidal or ovate, almoſt bald, but always with large teeth in the anterior part, and with the margins ciliate[6].

Allioni deſcribes his *hirſuta*; which he makes ſynonymous with Haller's plant deſcribed above, as having elliptic wedge-ſhaped leaves, hirſute all over, and ſomewhat viſcid, bluntly toothed in the wider part, and a many-flowered umbel. Colour of the flower violet-purple, with the neck whitiſh and contracted: border deeply cut to the neck; ſegments cordate, deeply emarginate, border flat. Scape round hirſute.

[1] Curtis. Smith. [2] Curtis. [3] Engl. bot. [4] Curtis magaz. [5] Idem. [6] Haller.

Calyx hirſute, with the ſegments longer than in *P. Auricula*. Tube of the corolla a little hirſute. It has nothing mealy in it. In the very high alps it is ſometimes very ſmall and one-flowered.

Native of the mountains of Carinthia and Switzerland. Allioni ſays the *hirſuta* begins where the *Auricula* ends, and is common in ſimilar places in the whole chain of the Alps from monte Veſulo into Savoy, and ſo to Switzerland.

β. The colour of the corolla in this variety is an elegant deep red, with a yellow eye; the leaves are longer and run down into a flat petiole to the root: though they are not ſo villoſe, yet they are not without very ſmall hairs, eſpecially towards the edges [f].

Mr. Curtis remarks, that with us it is ſo ſlightly villoſe as ſcarcely to deſerve that epithet, that it varies in the brilliancy of its colours, and is ſometimes white: he adds that Jacquin's plant does not quite agree with his. In Curtis's figure, the flowers are purple with a white eye, and the leaves are much ſhorter and broader than in Profeſſor Jacquin's: but large allowances may be made in plants that are ſo variable.—Native of Carinthia.

P. villoſa was introduced here in 1768, by Profeſſor de Sauſſure [g].

9. Leaves very ſmooth. Scape twice as high as the leaves. Involucre ſmall. Segments of the border in the corolla obcordate.—Native of the mountains of Dauria [h].

10. This reſembles *P. farinoſa*, but is much handſomer. The leaves are not mealy underneath, though paler; but they are longer. Scape higher. Bractes much longer. Flowers fewer, five or thereabouts. The calyxes have ſhort black hairs ſcattered over them, and are almoſt cut to the bottom; they are marked with five raiſed lines, are not mealy, but much larger. Tube of the corolla purple, very long and ſlender, an inch and half in length, and ſtanding high up above the calyx. Flower handſomer, violet-coloured not red, with narrower, ſemibifid ſegments; at the origin of each a ſpongy ſubſtance, forming a white ſpot, and all together a white eye [b].

It differs then from *P. farinoſa*, in having the leaves leſs mealy and leſs deeply toothed, the ſcape higher, fewer flowers in the umbel with the leaves of the involucre longer, the tube of the corolla three times as long, and the ſegments of the border narrower and of a violet purple colour [c].

Native of the mountains of the Upper Valais, Tyrol, Carinthia, Carniola, Italy and Croatia.

11. This has the ſtature of *P. farinoſa*. The umbel has from five to ſeven ſeſſile flowers. The involucre is from five to ſeven-leaved, the ſame length with the tube of the corolla. Calyx obovate, wrinkled. Segments of the corolla obcordate, violet-coloured. It has a ſmell like that of *Orchis conopſea*.

Native of the higher Alps, bordering on the ice and ſnow in Upper Carinthia and the Tyrol [d]. Introduced in 1777, by Meſſ. Kennedy and Lee [e].

12. In its farinaceous tendency this ſpecies accords with *P. Auricula*, but it is very unlike that in its wild ſtate, the leaves being much narrower, the flowers larger, and of a different colour. It differs from *glutinoſa* in the ſhortneſs of its involucre: from *villoſa* in having leaves much narrower, perfectly ſmooth in reſpect to *villi*, and in the colour of the flowers, which approaches to that of Lilac; but more eſpecially in its diſpoſition to become mealy, particularly on the edges of the leaves, between the ſerratures, where the mealineſs is ſo ſtrong as to make the leaf appear with a white or ſilvery edge. It is a delicate pretty plant, with a pleaſing muſky ſmell, and flowers in march and april.

Mr. Lee, of Hammerſmith, received it from the Alps in 1781, and it has continued unaltered by culture [f].

13. Leaves fleſhy, ſucculent, with the edges mealy, ſerrated, or entire according to Haller; deeply and equally toothed all round as Allioni affirms: but Scopoli ſays, the young leaves are entire, the adult ones ſerrate above the middle. Petioles leafy or winged. Leaflets of the involucre unequal, wide, lanceolate or blunt. Flowers very ſweet, four or five, in an upright umbel. Calyx one third of the length of the tube of the corolla, bell-ſhaped, toothed, mealy, as is alſo the ſcape. Tube of the corolla gradually widening upwards, not contracted at the neck: border concave, the ſegments emarginate but not deeply, and not cut to the neck. The moſt common colours are yellow or red, but it is found alſo purple and variegated, with a white eye powdered with meal. Capſule ſpherical or nearly ſo, flatted a little at top, of a coriaceous-cartilaginous ſubſtance, ſprinkled with meal; Haller ſays it is ſix-valved [g].

Native of the mountains of Switzerland, Auſtria, Styria, Carniola, Savoy and Piedmont; alſo about Aſtracan. It flowers in april and may. From Gerarde's herbal it appears that the Auricula was cultivated here in 1597. He calls it Mountain Cowſlip or Bear's-ear. Parkinſon ſays, "we in Engliſh call "them Bear's-ears, according to the Latin, or as they "are named by divers women *French Cowſlips*; they "may alſo be called *Mountain Cowſlips*." Ray names it *Bear's-ear, Oricola* or *French Cowſlip*. But all theſe are now diffuſed; and *Auricula* is become the general name.

The deſcription given above is from the wild plant of the Alps. The three principal varieties only are given, whence the innumerable cultivated ones are all derived. They differ not only in the colour of the corolla, but in the number of its ſegments, and of the ſtamens; not to inſiſt upon the difference obſervable in the leaves.

To ſhow what culture can perform in this ſpecies, we may mention from Morant's Colcheſter [h], that Henry Stow, of Lexden near that place, a famous raiſer of Auriculas, had ſome plants with no leſs than 133 bloſſoms upon one ſtem.

Gerarde figures the yellow, purple, red, ſcarlet, bluſh-coloured, and bright red, moſt of which grew then in the London gardens: but there does not ſeem to have been any attention paid to raiſing varieties from ſeed.

Parkinſon, in 1629, enumerates many varieties: 1. Purple or Murrey, with a white eye. 2. The ſame without any eye. 3. Tawny. 4. Deep or blood-red. 5. Violet. 6. Spaniard's bluſh. 7. Scarlet or light red. 8. Roſe-coloured. 9. Great White. 10. Leſſer White. 11. Greateſt fair Yellow. 12. Greater Yellow. 13. Great Straw-coloured. 14. Leſſer Straw-coloured. 15. Leſſer Yellow. 16. Deep Yellow. 17. Bluſh. 18. Hair-coloured. 19. Yellow Variable. 20. Green Variable.

"Many other varieties (he adds) were to be found, "with thoſe that are curious conſervers of theſe de-"lights of nature, either naturally growing on moun-"tains,—or raiſed from ſeed, as is more probable: "for ſeveral varieties have been obſerved to be got-"ten by ſowing of the ſeeds, every year lightly ſhew-"ing a diverſity, not obſerved before, either in the "leaf, or in the flowers."

The raiſing varieties from ſeed was then well known, but regular canons for diſtinguiſhing a good flower were not yet eſtabliſhed, as they probably were when the complete Florilege was publiſhed by John Rea, Gent. In the third edition of this work, printed at London in 1702, folio, we have the following Auriculas: *Purples*. 1. Fair Downham, one of the firſt good flowers that we had, named from the firſt owner, my very good friend Mr. John Downham, a reverend divine, and an induſtrious florift. 2. Mr. Good's purple, raiſed by Mr. Auſten of Oxford, and given to Mr. John Good of Baliol College. 3. Mrs. Buggs her fine purple, raiſed by her in Batterſey. 4. Mr. Whitſhore's purple, raiſed by my worthy friend William Whitmore, of Balmer near Hodgſden, Eſq. 5. Purple Fraufway. 6. Black Imperial. 7. Black Em-

perour.

perour. 8. Purple-ſtriped. 9. Purple and lemon-colour ſtriped.

Red or *Scarlet-coloured*. 10. Mr. Auſten's Scarlet, is one of the beſt. Divers other excellent flowers have been raiſed in Oxford by Mr. Jacob Bobart, keeper of the public garden.

There are divers ſorts of Reds, upon which fantaſtical names have been impoſed—as 11. Fair Virgin. 12. Matron. 13. Alderman. 14. Mercury, and the other Planets. 15. The Cow. 16. The Red Bull, &c.

Yellows, of ſmall eſteem. Some of the Buff colours have been in good eſteem, and every Floriſt had his *Leather-coat*,—as Tradeſcant's, Lances, Tuggies, Turners, Collins, Lookers, Humphries, Meracows, Mows, Mullars, Randols, and Rickets Beazar, all good kinds of Leather-coats: and I have raiſed a Leather-coat myſelf from ſeeds, not inferior to the beſt.

White—of ſmall variety and eſteem: the beſt is called Virgin's milk.]

But to enumerate all the diverſities of this plant would be almoſt endleſs; for every year produces vaſt quantities of new flowers, differing in ſhape, ſize and colour: in the leaves alſo there is a great variety, ſo that the ſkilful floriſt can often diſtinguiſh the varieties from them.

It ſeldom happens that ſuch flowers as are in great eſteem at one time, continue to be regarded a few years after; ſtill finer or larger flowers being produced from ſeeds, and as the names convey little, and there are no deſcriptions of them, it is needleſs to give a liſt of them.

[The catalogue of Meſſrs. Maddock, of Walworth contains near five hundred varieties. The modern names are generally from ſome great perſonage, with the raiſers or floriſts name prefixed.

The properties of a fine Auricula are theſe:

1. The ſtem ſhould be ſtrong, upright, and of ſuch a height as that the umbel of flowers may be above the foliage of the plant.

2. The peduncles or foot-ſtalks of the flowers ſhould alſo be ſtrong, and of a length proportional to the ſize and quantity of the flowers; which ſhould not be leſs than ſeven in number, that the umbel may be regular and cloſe.

3. The tube, eye, and border ſhould be well proportioned; which they will be, if the diameter of the firſt be one part, of the eye three, and the whole border ſix parts or thereabouts.

4. The circumference of the border ſhould be round or nearly ſo, or at leaſt not what is called ſtarry.

5. The anthers ought to be large, bold and fill the tube well; and the tube ſhould terminate rather above the eye, which ſhould be very white, ſmooth and round, without cracks, and diſtinct from the ground-colour.

6. The ground-colour ſhould be bold and rich, and regular, whether it be in one uniform circle, or in bright patches; it ſhould be diſtinct at the eye, and only broken at the outer part into the edging: a fine black, purple, or bright coffee-colour contraſt beſt with the white eye; a rich blue, or bright pink is pleaſing, but a glowing ſcarlet or deep crimſon would be moſt deſirable, if well edged with a bright green; this however can ſeldom be expected.

The green edge is the principal cauſe of the variegated appearance in this flower, and it ſhould be in proportion to the ground-colour, that is, about one-half of each.

The darker grounds are generally covered with a white powder, which ſeems neceſſary, as well as the white eye, to guard the flower from the ſcorching heat of the ſun's rays[1].]

All flowers that want any of the above properties, are turned out into the borders of the garden or rejected wholly by every good floriſt; for as there are varieties every year from ſeeds, the bad ones muſt make room for their betters; but in ſome the paſſion for new flowers ſo much prevails, that ſuppoſing the old flower to be greatly preferable to a new one, the latter muſt take place, becauſe it is of their own raiſing.

[14. This very lofty ſpecies is a native of Siberia, and varies with a ſtem only eighteen inches high.

15. Root round, white within, blackiſh without, putting out very long whitiſh fibres horizontally, forming very large thick tufts, loaded with abundance of flowers. Leaves widening at the end, and there cut with from four to ſeven acuminate teeth, but quite entire at the ſides, ſeſſile, thickiſh, about half an inch long. Scape axillary, obſoletely triangular, ſmooth, erect, the length of the leaves or much ſhorter. Flower ſolitary, terminating, erect, ſupported by one or two linear bractes ſhorter than the calyx. Calyx round, almoſt half-five-cleft, blunt, ſmooth. Corolla purple: tube funnel-ſhaped, not contracted at the neck, commonly longer than the leaves, always longer than the calyx, ſometimes twice as long, whitiſh and hirſute within; border of the ſame length, with ſemibifid ſegments. Filaments in the lower part of the tube, often at the very bottom. Capſule very blunt, ſhining, brown[k].

Linneus ſays the corolla is yellow; Haller, Scopoli, Willdenow, that it is fleſh-coloured; Krocker and Jacquin that it is purple. Willdenow obſerves that it dries of a violet colour.

According to Haller, the root is large, the leaves very ſmall, with a right-lined, wide, ſerrate top, the ſcape ſcarcely a finger's length, with two ſharp narrow ſtipules (or bractes) and one or two inodorous flowers. It differs from the *villoſa* in having ſhining leaves not hirſute or bent in the arc of a circle, and much ſmaller; the flower lanuginoſe within, and the ſegments of the calyx blunt.

Scopoli ſays, the capſule is roundiſh, flat and red at top; containing as many as ſixty ſeeds, faſtened to an ovate, peduncled receptacle.

Native of mount St. Gothard, Schneeberg, and other mountains of Auſtria, &c. flowering from june to ſeptember.

16. In habit and ſtature this agrees with *P. Auricula*. The umbel is two or three-flowered, ſupported by an involucre of two, three or four linear leaflets the length of the peduncles. Tube of the calyx ſcarcely angular. Border of the corolla violet-coloured with ſemibifid ſegments: tube ſimple, without any contracted neck. Stamens in the middle of the tube. It varies very much in ſtature; nor does it grow in ſuch cloſe tufts as *P. minima*[l].

Haller ſays, that the leaves are ciliate at the edge; the ſcapes an inch or two inches in height, with one or two flowers at the top; the calyx bell-ſhaped, coloured, ſubhirſute.

According to Scopoli, the length of the calyx is one third part of the diameter of the corolla; the corolla red, the diameter of the border ſix or ſeven lines, the tube of the ſame length with the ſegments; filaments white; anthers yellow; germ green at the baſe, in other parts red and ſhining; ſtyle roſe-coloured, three lines in length; ſtigma pale green, gently inclining to one ſide. The flower has the ſmell of honey. Seeds from forty to fifty. He has found it with one flower only.

It is diſtinguiſhed from the next ſpecies, by having the leaves cartilaginous at the edge, ſcarce apparently crenulate or ciliate when examined with a magnifier; and the calyx tubular[m].

Native of the Swiſs, Pyrenean, Auſtrian, Styrian, and Carniolian mountains, as on Schneeberg, Etſcher, Struk near Idria, Grindovitz, Gothard, Speluga, &c. flowering towards the end of may; in gardens, where it flouriſhes very well, it flowers in april and may[n].

17. Leaves membranaceous, blunt, ſubrepand, not cartilaginous at the edge. Calyxes abbreviated.—Native of Carniola, in Idria, at the foot of a hill called Kobila[o].

18. Leaves ſmooth; calyxes tubular, blunt.—Native of the mountains of Norway[p].

[1] Maddock, 151.

[k] Jacqu. vind. [l] Jacqu. vind. and obſ. [m] Willdenow. [n] Jacquin. [o] Willdenow. [p] Retz. ſcand.

19. Root thick, at firſt duſky, then white, ſiliform, whence ariſe on a petiole an inch in length tongue-ſhaped leaves, a hand's breadth long, clammy, having a bituminous ſmell, finely villoſe, pale underneath, ſinuate, quite entire, in ſhape reſembling thoſe of *Cynoglossum vulgare*. Flowers pale blue, ſix or ſeven in an umbel, each on its proper pedúncle. Involucre of as many ſmall leaflets as there are pedúncles.

Native of the mountains of Piedmont, on rocks about the baths of Valderia[s].

20. Native of Siberia, in moiſt meadows, from the river Obo to the country beyond the lake Baikal.—Leaves ſmooth[t].]

PROPAGATION AND CULTURE.

2, 3, 4. The roots of the wild plants may be taken up and tranſplanted into gardens at michaelmas, that they may have ſtrength to produce their flowers early in the ſpring. They delight in a ſtrong ſoil, but will grow in almoſt any ſort of earth. The Primroſe ſhould have a ſhady ſituation.

POLYANTHUS.

The Polyanthuſes are all varieties of theſe, and have been ſo much increaſed and improved in the laſt century, as almoſt to equal the Auricula; and in ſome parts of England they are ſo much eſteemed as to ſell for a guinea a root, ſo that a great variety is continually raiſed, and many perſons are engaged in the culture of it.

The ſeveral varieties of Polyanthuſes are produced by ſowing of ſeeds, which ſhould be ſaved from ſuch flowers as have large upright ſtems, producing many flowers upon a ſtalk, which are large, beautifully ſtriped, open flat, and not pin-eyed. From the ſeeds of ſuch flowers there is room to hope for a great variety of good ſorts, but there ſhould be no ordinary flowers ſtand near them, leſt, by the mixture of their farina, the ſeeds ſhould be degenerated.

Theſe ſeeds ſhould be ſown in boxes filled with light rich earth in december, being very careful not to bury the ſeed too deep; for if it be only ſlightly covered with light earth, it will be ſufficient. Theſe boxes ſhould be placed where they may have the benefit of the morning ſun until ten of the clock, but muſt by no means be expoſed to the heat of the day, eſpecially when the plants begin to appear; for at that time, one whole day's ſun will entirely deſtroy them. In the ſpring, if the ſeaſon ſhould prove dry, you muſt often refreſh them with water, which ſhould be given very moderately; and, as the heat increaſes, you ſhould remove the boxes more in the ſhade, for the heat is very injurious to them.

By the middle of may theſe plants will be ſtrong enough to plant out, at which time you ſhould prepare ſome ſhady borders which ſhould be made rich with neats dung, upon which you muſt ſet the plants about four inches aſunder every way, obſerving to water them until they have taken root; after which they will require no farther care but to keep them clear from weeds, until the latter end of auguſt following, when you ſhould prepare ſome borders which are expoſed to the eaſt, with good light rich earth, into which you muſt tranſplant your Polyanthuſes, placing them ſix inches aſunder equally in rows, obſerving, if the ſeaſon proves dry, to water them until they have taken root; in theſe borders your plants will flower the ſucceeding ſpring, at which time you muſt obſerve to mark ſuch of them as are fine to preſerve, and the reſt may be tranſplanted into wilderneſſes, and other ſhady places in the garden, where, although they are not very valuable flowers, they will afford an agreeable variety.

Thoſe which you intend to preſerve, may be removed ſoon after they have done flowering (provided you do not intend to ſave ſeeds from them), and may be then tranſplanted into a freſh border of the like rich earth, allowing them the ſame diſtance as before, obſerving alſo to water them until they have taken root; after which they will require no farther care, but only to keep them clean from weeds, and the following ſpring they will produce ſtrong flowers, as their roots will be then in full vigour; ſo that if the kinds are good, they will be little inferior to a ſhew of Auriculas. Theſe roots ſhould be conſtantly removed and parted every year, and the earth of the border changed, otherwiſe they will degenerate, and loſe the greateſt part of their beauty.

If you intend to ſave ſeeds, which is the method to obtain a great variety, you muſt mark ſuch of them, which, as I ſaid before, have good properties. Theſe ſhould be, if poſſible, ſeparated from all ordinary flowers, for if they ſtand ſurrounded with plain-coloured flowers, they will impregnate each other, whereby the ſeeds of the valuable flowers will not be near ſo good, as if the plants had been in a ſeparate border, where no ordinary flowers grew; therefore the beſt way is to take out the roots of ſuch as you do not eſteem as ſoon as the flowers open, and plant them in another place, that there may be none left in the border, but ſuch as you would chuſe for ſeed.

The flowers of theſe ſhould not be gathered, except ſuch as are produced ſingly upon pedicels, leaving all ſuch as grow in large bunches; and if the ſeaſon ſhould prove dry, you muſt now and then refreſh them with water, which will cauſe their ſeed to be larger, and in greater quantity, than if they were entirely neglected. In june the ſeed will be ripe, which may be eaſily known by the pods changing brown and opening; ſo that you ſhould at that time look over the plants three or four times a week, gathering each time ſuch of the ſeed-veſſels as are ripe, which ſhould be laid upon a paper to dry, and may then be put up until the ſeaſon of ſowing.

As the plants which ariſe from ſeeds, generally flower much better than offſets, thoſe who would have theſe flowers in perfection, ſhould annually ſow their ſeeds.

[Polyanthuſes blow at the ſame time, and require nearly the ſame treatment as Auriculas, both with reſpect to ſoil and ſituation; they are however more impatient of heat and drought, and more partial to ſhade and moiſture. They may be ſet in the ſame-ſized pots, and in the ſame compoſt as the Auricula, only with the addition of more loam: or they may be planted on cool ſhady beds or borders, being very hardy, and ſeldom periſhing in the coldeſt and wetteſt ſeaſons, becauſe their parent is a native of this country; but during the heats of ſummer they are frequently deſtroyed, unleſs proper precautions be taken[r]. This diſlike of heat, ſeems to indicate that the Polyanthus is rather the offspring of the Primroſe, which requires ſhade, than of the Cowſlip, which grows in open paſtures; though Mr. Miller ſeems to regard it as a variety of the latter.

The Polyanthus is very liable to the depredations of ſnails and ſlugs, in the ſpring of the year; the plants and pots therefore ſhould be carefully examined on all ſides early in the morning. But its worſt enemy is a ſmall red ſpider or Acarus, which in ſummer forms its web on the under ſide of the leaves. Theſe little inſects, ſcarcely viſible without a magnifying glaſs, cauſe the leaves to become yellow and ſpotted, and eventually deſtroy the plant: they multiply with ſuch rapidity as to take poſſeſſion of a whole collection, in a very ſhort time.

Such plants as appear infected ſhould be immediately ſelected from the reſt, taken up, and ſoaked for two or three hours in a ſtrong infuſion of tobacco water, and then replanted in a freſh ſoil or compoſt, and removed to a ſituation at a diſtance from the former. But if the whole bed or border be overrun with this inſect, it is beſt to take up all the plants, and having ſoaked them, to plant them elſewhere.

The bed or border ſhould then be trenched up, and remain fallow to the next ſeaſon, or be planted with another crop not liable to this calamity.

Polyanthuſes may be increaſed by ſlips or offſets, taken off when the plants are freſh potted[t]. For other particulars, ſee P. AURICULA.

[s] Allioni. [t] Gmelin.

[r] Maddock, 219. [t] Idem, 220.

5. The Bird's-eye ſeeds readily in its wild ſtate, and alſo frequently when cultivated: but it is ſcarcely worth the pains to raiſe it from ſeed, ſince a ſtrong root may be divided ſo as to form many plants; the beſt time for doing this is in the ſpring, ſoon after the leaves are expanded. Place each offset in a ſeparate pot, filled with two parts of ſtiffiſh loam, and one part light ſandy bog-earth; water and ſet them in the ſhade, under a north wall or paling, but not under trees; keep them there during ſummer in pans of water, but in the autumn, as the wet ſeaſon comes on, take them out of the pans, and either lay the pots on their ſides, or place them during winter under a common cucumber frame, to keep them from immoderate wet, which this plant cannot bear, although it be a native of boggy meadows. The next, if not the ſame year, theſe plants will blow ſtrong; and thus they ſhould be treated every year, for Primulas in general require to have their roots frequently parted.

6. This is a hardy plant of ready growth, and will ſucceed either in the pot or border, by guarding it from the ſun in ſummer, and from ſevere froſt and too much wet in winter. It is increaſed by parting the roots, either in ſeptember or at the beginning of march. It is very liable to be injured by the Aphides or Plant-Lice.

7. Being yet a rare plant, this muſt be treated with care, as was directed for the fifth ſort. It may be raiſed from ſeeds, or increaſed by parting the roots; but it is apt to be loſt, if not duly attended to.

8. This may be treated like the three former ſorts, or as directed for the round-leaved Cyclamen.

12. This is a very delicate plant. To ſucceed in its cultivation, it ſhould be placed in a pot of ſtiffiſh loam, mixed with one third rotten leaves, bog-earth, or dung, and plunged in a north border, taking care that it does not ſuffer for want of water in dry ſeaſons; thus treated, it increaſes by its roots nearly as readily as the Auricula; and may be propagated by parting theſe in april or ſeptember*.

The above directions will amply ſuffice for the increaſe and management of the other alpine Primulas.]

13. Auricula.

In order to obtain good flowers from ſeeds, you muſt make choice of the beſt flowers you have, which ſhould be expoſed to the open air, that they may have the benefit of ſhowers, without which they ſeldom produce good ſeeds: the time of their ripening is in june, which you will eaſily know, by their ſeed-veſſel turning to a brown colour, and opening; you muſt therefore be careful leſt the ſeeds be ſcattered out of the veſſel, for it will not be all fit to gather at the ſame time.

The time for ſowing this ſeed is commonly in auguſt, but if it be ſown any time before Chriſtmas, it will be time enough.

The beſt ſoil for this ſeed is good, freſh, light, ſandy mould, mixed with very rotten neats dung, or very rotten dung from the bottom of an old hot-bed: with this fill the pots, boxes or baſkets in which the ſeeds are to be ſown; and having levelled the ſurface very ſmooth, ſow the ſeeds thereon, ſifting over them a little rotten willow mould; then cover them with a net or wire, to prevent cats or birds from ſcratching out, or burying the ſeeds; in which caſe they remain a year in the ground before the plants appear, if they ever appear at all. Many perſons never cover the ſeeds, but leave them on the ſurface, for the rain to waſh them into the ground, which is often the beſt method. Let the boxes, &c. be placed ſo as to receive half the day's ſun, during the winter ſeaſon; but in the beginning of march, remove them where they may have only the morning ſun till ten o'clock; for the young plants will now ſoon begin to appear, which, if expoſed to one whole day's ſun only, will be all deſtroyed.

During the ſummer ſeaſon, in dry weather, often refreſh them with water, but never give them too great a quantity at once. In july following, the plants will be large enough to tranſplant, at which time you muſt prepare a bed, or boxes, filled with the above-mentioned ſoil, in which you may plant them about three inches ſquare; and (if in beds) you muſt ſhade them every day, till they are thoroughly rooted, as alſo in very hot dry weather; but if they are in baſkets or boxes, they may be removed to a ſhady place.

When the ſeedling Auriculas are planted in beds, there ſhould be ſome rotten neats dung laid about ten inches under the ſurface, and beaten down cloſe and ſmooth: this will prevent the worms from drawing the young plants out of the earth, which they generally do where this is not practiſed. This dung ſhould be laid about half a foot thick, which will entirely prevent the worms getting through it until the plants are well eſtabliſhed in the beds; and the roots of the Auriculas will ſtrike down into the dung by the ſpring, which will make their flowers ſtronger than uſual: theſe beds ſhould be expoſed to the eaſt, and ſcreened from the ſouth ſun.

When you have taken all your plants, which are now come up, out of your boxes or pots, level the earth gently again; for it often happens, that ſome of the ſeeds will lie in the ground two years before they appear, eſpecially if they were covered too deep when ſown, as was before obſerved.

The ſpring following many of theſe flowers will ſhew, when you may ſelect ſuch of them as have good properties, which ſhould be removed each of them into a pot of the ſame prepared earth, and preſerved until the next ſeaſon, at which time you will be capable to form a judgment of the goodneſs of the flower; but thoſe that produce plain-coloured or ſmall flowers, ſhould be taken out, and planted in borders in the out-parts of the garden, to make a ſhew, or gather for noſegays, &c. the others, which do not produce their flowers the ſame year, may be taken up, and tranſplanted into a freſh bed, to remain till you ſee how they will prove.

The manner of propagating theſe flowers when obtained, is from offsets, or ſlips, taken from the old roots in april, when the flowers are in bloom: theſe offsets muſt be planted into ſmall pots filled with the ſame ſort of earth as was before directed for the ſeedlings, and, during the ſummer ſeaſon, ſhould be ſet in a ſhady place, and muſt be often (but very gently) refreſhed with water; but in the autumn and winter ſhould be ſheltered from violent rains. The ſpring following theſe young plants will produce flowers, though but weak; ſoon after they are paſt flowering, you muſt put them into larger pots, and the ſecond year they will blow in perfection.

But, in order to obtain a fine bloom of theſe flowers, you muſt obſerve the following directions.

Firſt, Preſerve your plants from too much wet in winter, which often rots and ſpoils them; but let them have as much free open air as poſſible; nor ſhould they be too much expoſed to the ſun, which is apt to forward their budding for flower too ſoon; and the froſty mornings, which often happen in march, thereby deſtroy their buds, if they are not protected therefrom. To prevent which, thoſe who are very curious in theſe flowers, place their pots in autumn under a common hot-bed frame, where, in good weather, the plants may enjoy the full air, by drawing off the glaſſes; and in great rains, ſnow, or froſt, the plants may be ſcreened by covering them. Where this method is practiſed with judgment, the flowers will be much ſtronger, and the plants will increaſe faſter than when they are expoſed abroad.

Secondly, In the beginning of february, if the weather is mild, you muſt take off the upper part of the earth in the Auricula pots, as low as you can without diſturbing their roots, and fill up the pots with freſh rich earth, which will greatly ſtrengthen them for bloom; as alſo prepare your offsets for tranſplanting in april, by cauſing them to puſh out new roots.

Thoſe plants which have ſtrong ſingle heads, always produce the largeſt cluſters of flowers; therefore the curious floriſts pull off the offsets as ſoon as it can be done with ſafety to their growing, to encourage the

mother

* Curtis.

mother plants to flower the ſtronger; they alſo pinch off the flowers in autumn, where they are produced, and ſuffer them not to open, that the plants ſhould not be weakened thereby.

Thirdly, You muſt cover your pots with mats in froſty weather, during this time of their budding for flower, leſt the ſharp mornings blight them, and prevent their blowing.

Fourthly, When your flower-ſtems begin to advance and the bloſſom buds grow turgid, you muſt protect them from haſty rains, which would waſh off their white meally farina, and greatly deface the beauty of their flowers; but at the ſame time obſerve to keep them as much uncovered as poſſible, otherwiſe their ſtems will be drawn up too weak to ſupport their flowers (which is often the caſe when their pots are placed near walls) give them gentle waterings to ſtrengthen them, but let none of the water fall into the center of the plant, or among the leaves.

Fifthly, when your flowers begin to open, you ſhould remove their pots upon a ſtage (built with rows of ſhelves, one above another, and covered on the top, to preſerve them from wet: this ſhould be open to the morning ſun, but ſheltered from the heat of the ſun in the middle of the day:) in this poſition they will appear to much greater advantage, than when the pots ſtand upon the ground; for, their flowers being low, their beauty is hid from us; whereas, when they are advanced upon ſhelves, we ſee them in a full view. In this ſituation they may remain until the beauty of their flowers is paſt, when they muſt be ſet abroad to receive the rains, and have open free air, in order to obtain ſeeds, which will fail if they are kept too long under ſhelter. When your ſeed is ripe, obſerve to gather it when it is perfectly dry, and expoſe it to the ſun in a window upon papers, to prevent its growing mouldy, and let it remain in the pods till the ſeaſon for ſowing it.

[Thoſe who are very nice in raiſing Auriculas, direct the compoſt to be made of one half rotten cow-dung two years old; one ſixth freſh ſound earth of an open texture; one eighth earth of rotten leaves; one twelfth coarſe ſea or river ſand; one twenty-fourth ſoft decayed willow wood; one twenty-fourth peaty or moory earth; one twenty-fourth aſhes of burnt vegetables, to be ſpread upon the ſurface of the other ingredients.

This compoſt is to be expoſed to the ſun and air, turned over once or twice, and paſſed as often through a coarſe ſkreen or ſieve: then it ſhould be laid in a regular heap from fifteen to eighteen inches thick, and in this ſtate remain a year, turning it over two or three times, and keeping it free from weeds.

The pots for Auriculas ſhould be hard baked: the inner diameter of the top ſhould be ſix inches and a half, of the bottom four inches, and they ſhould be about ſeven inches deep, for common-ſized blooming plants: but ſmaller plants and offſets ſhould have ſmaller ſhallower pots, and very large plants ſhould have larger pots in proportion; the bottom ſhould have a ſmall degree of concavity, and the hole ſhould be half an inch in diameter: the rims ſhould project about half an inch, in order to take up and remove them with greater eaſe and ſafety. The pots ſhould be buried in wet earth, or immerſed in water three or four days or a week, before they are wanted, to take off their abſorbency.

Tranſplant or pot the Auriculas annually ſoon after bloom; curtailing their fibres, if grown very long, and cutting off the lower part of the main root, if too long or decayed. The offſets at this ſeaſon ſtrike freely, and become well eſtabliſhed before winter. Examine the plant carefully, and where any unſoundneſs appears, cut it out entirely with a ſharp penknife; expoſe the wounded part to the ſun, and when it is quite dry, apply a cement of bees-wax and pitch in equal quantities, ſoftened in the ſun or before a fire. If the lower leaves be yellow or dried up, ſtrip them off in a direction downwards. Having put the hollow ſhell of an oyſter over the hole of the pot, fill three parts of it with compoſt, higheſt in the middle, place the plant there, with its fibres regularly diſtributed all round; then fill the pot with the compoſt adding a little clean coarſe ſand cloſe round the ſtem on the ſurface, and ſtrike the bottom of the pot againſt the ground or table to ſettle the earth.

The true depth to plant an Auricula is within half an inch of the loweſt leaves, becauſe the moſt valuable fibres proceed from that part; and the offſets will be thereby encouraged to ſtrike root ſooner. When theſe have formed one or more fibres of an inch or two in length, they may, by means of a piece of hard wood, or by the fingers, be ſeparated with ſafety, and planted round the ſides of a ſmall pot, filled with the ſame compoſt, till they are ſufficiently grown to occupy each a ſeparate pot: if a ſmall hand glaſs be placed over each pot it will cauſe the fibres to grow more rapidly; but if it be long continued, it will draw up and weaken the plants.

In the beginning of may, as ſoon as the operation of potting is finiſhed, the plants are to be placed in an airy, ſhaded ſituation, but not under the drip of trees. Here they are to remain till ſeptember or october, when they ſhould be removed into ſhelter.

In the firſt favourable weather in february diveſt the plants of their decayed leaves; and by the middle of that month earth them up; that is, take away the ſuperficial mould of the pots about an inch deep, and put in freſh compoſt, with the addition of a little loam, to give it more tenacity. This will contribute greatly to the ſtrength of the plants, and the vigour of their bloom; at the ſame time it will afford a favourable opportunity to ſeparate ſuch offſets as appear to have ſufficient fibre to be taken off at this early ſeaſon. The pots with theſe offſets ſhould be placed in a frame, in a ſheltered ſituation till their roots are eſtabliſhed.

Though froſt, unleſs it be very rigorous, will not deſtroy the plants, yet it will injure them, and perhaps ſpoil the bloom, eſpecially early in the ſpring: they ſhould therefore be covered with mats in a ſevere ſeaſon.

If any plant has more than one or two principal ſtems, it is adviſeable to pinch off the ſmalleſt and weakeſt, in order to render the bloſſoms of that which remains larger and more vigorous.

When the flowers (technically pips) become turgid, and begin to expand, ſelect the plants from the reſt, remove them to a calm ſhady corner, and ſuſpend ſmall hand-glaſſes over them.

The ſtage for the pots to ſtand on whilſt in bloom ſhould have a northen aſpect, and ſhould conſiſt of four or five rows of ſhelves, riſing one above another. The roof ſhould conſiſt of frames of glaſs. The talleſt blowing plants ſhould be placed behind, and the ſhorteſt in front. They muſt be regularly watered two or three times every week during the bloom.

In raiſing the Auricula from ſeed, if the boxes in which the ſeed is ſown be placed on the ſurface of a hot-bed, in a cucumber or melon frame, the ſeeds will begin to vegetate in about three weeks. The earth muſt be kept moderately moiſt, by ſprinkling it with a hard clothes-bruſh, dipped in ſoft water, warmed by ſtanding in the ſun. At the end of four or five weeks, when the young plants will be all come up, they muſt have gradually more air, and in a fortnight or three weeks the boxes ſhould be taken out of the frame, and placed in a warm ſituation, though not too much expoſed to the ſun till towards the end of april, when they may be removed to a cooler aſpect, where they can receive the ſun only till nine o'clock; and in may they ſhould be placed in the moſt cool and airy part of the garden; ſtill not neglecting to keep the earth moderately moiſt, and to protect them from violent rains.

As ſoon as any of the plants ſhow ſix leaves, tranſplant them into other boxes an inch and half or two inches aſunder: and when they are grown ſo as to touch each other, tranſplant them a ſecond time into larger boxes, at the diſtance of three or four inches, or into ſmall pots, where they may remain till they blow: and then ſuch as are very good ſhould be marked, and the bad ones deſtroyed. As ſoon as the bloom is over, thoſe that are marked ſhould be planted ſeparately in pots, and

taken

taken care of till they blow again, when their merit may be more accurately aſcertained. A great proportion of theſe ſeedlings will be plain-coloured (technically ſelf;) which are of no value but as common border flowers, unleſs they have good properties in other reſpects, or are ſingularly beautiful or brilliant in their colours[s].

Leaves roundiſh quite entire.]

DESCRIPTIONS, *&c.*

1. This riſes with a ſhrubby ſtalk to the height of eight or ten feet, ſending out many branches from the ſides the whole length. Leaves lanceolate, about three inches long, and one inch broad in the middle, terminating in an acute point, of a deep green, veined on the under ſide, alternate on the branches upon ſlender footſtalks. The flowers come out from the ſide of the branches, ſingle or two or three at each joint. Berries the ſize of Holly, turning purple when ripe. It flowers in july, and the ſeeds ripen in the winter.

[s] Maddock's Floriſt's Directory, 111—151.

[According to Du Roi, it varies with a ſeven-cleft, and ſometimes though rarely with an eight-cleft flower, having ſeven or eight ſtamens. Juſſieu alſo ſays, that it has ſometimes only five clefts in the flower and five ſtamens, and from five to eight ſeeds. Gronovius affirms that it is dioecous.]

Native of Virginia, and according to Mr. Miller, of other parts of North America. [Kalm obſerved it near Philadelphia.—It was introduced in 1736, by Peter Collinſon, Eſq.[t]

2. Leaves alternate, petioled, oblong, of a firm texture, ſmooth, acute, nearly reſembling thoſe of *Myrica*; there are commonly two ſerratures towards the tip. Peduncles axillary, ſmall, commonly three-flowered[u].]

It is of lower growth than the preceding; the leaves are ſhorter, and ſerrate at their points only. It is a native of Canada.

[Neither Linneus nor Miller had ſeen the flowers. The ſynonyms which the former has given from Cateſby, and Miller's figures belong to *Ilex vomitoria*. It was cultivated by Mr. Miller in 1759, and flowers in july and auguſt[x].

3. This was introduced about 1778, by Mr. James Gordon, from what country is not known. It flowers in july[y].

4. Branches the thickneſs of a ſwan's quill, with a gray bark dotted here and there, round below, angular towards the tip: branchlets alternate, duſky purple, ſmooth, ſomewhat angular, compreſſed at the tip. Leaves frequent, alternate, two inches wide, in the male often rounder, terminated by a ſhort point; in the female oblong ovate ſometimes emarginate, all a little bent back at the edge, remotely and obſoletely ſerrate but quite entire towards the baſe, ſmooth on both ſides, veined, ſcarcely ſhining on the upper ſurface, underneath pale with a few ſmall raiſed dots ſcattered about. Petioles duſky purple, half an inch long, keeled underneath.—In the Male, peduncles axillary, about twenty, the length of the petiole, moſtly three-flowered, but ſome one-flowered. Pedicels very ſhort. Calyx very ſmall, four-cleft. Petals four, oblong. Stamens four, ſpreading, the length of the petals. Anthers roundiſh. The rudiment of a germ, without either ſtyle or ſtigma.—In the Female, peduncles fewer, ſhorter, all one-flowered. The flowers a little larger. Calyx and Corolla as in the Male. Stamens four, with effete anthers. Germ oblong, blunt. Found in the iſland of Montſerrat by Ryan.

5. Branches angular, ſmooth, compreſſed a little at the tip, duſky purple. Leaves alternate, from two to three inches in length, and often two inches wide, little acuminate, blunniſh, remotely and obſoletely ſerrate, towards the baſe quite entire and often acute, very ſmooth on both ſides, veined, ſhining on the upper ſurface, on the under paler and not dotted. Petioles half an inch long, brown. Peduncles axillary, five or ſix, the length of the petiole, all one-flowered, ſmooth, brown. Calyx four-cleft; the ſegments ovate. Petals four, ovate, ſpreading, finally reflex. Filaments four, erect, a little longer than the petals. Anthers oblong, erect. Germ roundiſh. Style ſcarcely any. Stigma acute. Berry ovate, roundiſh, the ſize of Black Pepper.

It is allied to the preceding, but differs in having the flowering-branches more ſlender, brown not whitiſh: the leaves thinner, more ſhining, commonly narrowed towards the baſe and acute: fewer peduncles, all one-flowered: the flowers twice as large and hermaphrodite. Found in Montſerrat by Ryan[z].

6. Trunk twenty or thirty feet high, with an even brown bark. Branches ſubdivided, almoſt upright, round ſmooth. Leaves alternate, acuminate at both ends, ſerrate on the whole margin; ſerratures remote, acute-nerved, ſmooth, an inch and half long, ſtiffiſh, when dried of a dark livid colour. Petioles ſhort, round, ſmooth. Peduncles axillary, ſolitary, ſhorter than the leaves, half an inch long, filiform, com-

[t] Hort. kew. [u] Linn. ſpec. [x] Hort. kew. [y] Idem. [z] Vahl, eclogæ.

preſſed a little, three-flowered or three-parted: pedicels one-flowered: flowers ſmall, white. Calyx ſix-cleft: ſegments ſmall, ovate, convex. Corolla divided almoſt to the baſe into ſix parts: ſegments ovate-lanceolate, ſpreading, bent back at the tip. Filaments inſerted between the diviſions of the corolla. Anthers roundiſh, bifid at the baſe. Germ roundiſh, ſuperior. Style very ſhort, thick, permanent. Stigma ſubcapitate, depreſſed, rolled back at the edge, ſubſexfid. Berry bluntly ſix-cornered, ſmall, umbilicated with the ſtigma, black when ripe. Seed oblong, compreſſed, ſhining, black. It very much reſembles *P. lucida* in the flowers and leaves; but in that ſpecies the leaves are ſerrate only at the tip, paler underneath, and of a leſs ſtout conſiſtence.

Native of Jamaica, in coppices on the higheſt mountains.

7. The wood of this tree is hard. Branches ſubdivided, round, with an aſh-coloured bark, unarmed. Leaves on ſhort petioles, alternate, nerved, veined, ſmooth on both ſides, paler underneath, ſomewhat coriaceous. Peduncles axillary, longer than the petioles, four to eight cluſtered together, one-flowered. Flowers ſmall, whitiſh. Calyx ſix-toothed. Corolla ſix-parted to the very baſe, ſo as to be in a manner ſix-petalled: ſegments obovate, ſpreading, permanent, with the tips erect. Filaments inſerted into the baſe of the corolla, alternating. Anthers oblong, incurved. Germ roundiſh, ſuperior. Style none. Stigma ſeſſile, ſubcapitate, ſix-ſtreaked. Berry crowned with the ſtigma preſſed cloſe. Seeds ſix, oblong, grooved, cloſely contiguous.

Native of the Caribee iſlands, St. Chriſtopher's and Montſerrat [d].]

PROPAGATION AND CULTURE.

1, 2. Theſe are propagated by ſeeds, ſown ſoon after they are ripe upon a bed of light earth, covering them about half an inch with the ſame ſort of earth. The ſeeds which are ſo ſoon put into the ground, will many of them come up the following ſpring; whereas thoſe which are kept longer out of the ground, will remain a whole year before the plants will appear, in the ſame manner as the Holly, Hawthorn, and ſome others. When the young plants come up, they may be treated in the ſame manner as has been directed for the American Hawthorns; theſe being full as hardy: but they delight in a moiſt ſoil and a ſhady ſituation. In hot land they make little progreſs, and rarely produce any fruit.

[d] Swartz, deſcr.

DESCRIPTION, *&c.*

This is a ſhrub with round branches. Leaves alternate, petioled, ovate, acuminate, ſerrate, ſmooth. Stipules linear. Flowers few, terminating, alternate, pedicelled; with linear bractes [e].—Stipules caducous. Peduncles from one to five, axillary, one-flowered, having one or two little ſcales in the middle [f]. Found in the iſland of Santa Cruz by Browne, who ſent it to Linnæus; and ſince that by Commerſon. Juſſieu ſuſpects it to be allied to *Laetia.*

The whole of this ſhrub is ſmooth; the bark of the branches is purpliſh. Leaves four inches long, or leſs, attenuated, ſcarcely cordate at the baſe, three-nerved, tender. Stipules ſickle-ſhaped, attenuated, a quarter of an inch long, toothed on the outer ſide to the very baſe, on the inner to the middle only. Racemes at the ends of the branchlets, from three to five-flowered. Peduncles filiform. Pedicels a little thicker under the flower, when mature longer than the common peduncle. Bracte towards the baſe of the pedicels. Calyx three or four-leaved: leaflets ovate, acute, ſmooth on the outſide, villoſe within, a little longer than the ſtamens. Style longer than the calyx. Berry globular, the ſize of a pea, mucronate with the permanent ſtyle. Seeds three-ſided, ſhining [g].

DESCRIPTION, *&c.*

Root creeping. Stems a foot high, roundiſh. Leaves alternate, lanceolate, ſerrate, ending in petioles; the lower or thoſe that are under water pinnatifid with linear ſegments. Flowers axillary, ſolitary. Fruit the ſame form as in *Polygonum* [h]. According to Gærtner, it is a three-ſided drupe, with each of the angles extended into a narrow membranaceous wing: the rind very thin, ſpongy-membranaceous: the ſhell whitiſh, three-celled; in each cell one oblong ſeed, acuminate downwards, of a pale reddiſh colour, faſtened by a thread aſcending from the baſe to the vertex of the ſeed, and faſtened to the inner ſide of it [i].

Native of Virginia in marſhes.

DESCRIPTION, *&c.*

This grows to a large tree, with a tolerably erect trunk; the bark deeply cracked, and of a dirty aſh-colour: branches irregular, very numerous, forming a globular, ſhady head: prickles ſcattered over the ſmall branches, but in ſome trees wanting. Leaves alternate, abruptly bipinnate, from two to three inches long; pinnas from one to four inches; when in pairs, oppoſite, and have a gland between; one inch and a half long. Leaflets oppoſite, from ſeven to ten pairs, obliquely lanceolate, ſmooth, entire, about half an inch long, and one ſixth of an inch broad. Stipules none. Spikes many, terminating, or from the exterior axils, filiform, nearly erect. Bractes minute, one-flowering, falling off. Flowers numerous, ſmall, yellow, ſingle, approximated. Calyx inferior, five-toothed. Petals linear-lanceolate, erect, recurved at the tip, ſmooth. Filaments united at the baſe, faſtened to the baſe of the petals, the length of the corolla. Anthers incumbent, fulvous, with a white gland at the apex of each, which falls off ſoon after the flower expands. Style crooked. Legume a ſpan in length, ſcarcely the thickneſs of a gooſe-quill, pendulous, not inflated. Seeds many, lodged in a brown, mealy ſubſtance.

It is a native of moſt parts of the Coromandel coaſt; flowering during the cold, and beginning of the hot ſeaſon.

The pod of this tree is the only part uſed; it is about an inch in circumference, and from ſix to twelve inches long; when ripe, it is brown, ſmooth, and contains, beſides the ſeeds, a large quantity of a brown mealy ſubſtance, which the natives eat; it has a ſweetiſh agreeable taſte, and may be compared to the Spaniſh Algaraba, or Locuſt-tree, Ceratonia Siliqua.

It is called *Tſhamie* by the Telingas; and *Vanni maram* by the *Tamuls**.]

   Leaves trifid filiform, ſtem erect, heads ſolitary encompaſſed with bractes.

3. Protea cyanoides.
   Lin. ſyſt. 136. *ed. Willd.* 507. *Reich.* 1. 260. *mant.* 188. *Thunb. prodr.* 25. *diſſ. n.* 3.

Leucadendron cyanoides. *Lin. ſpec.* 137. *Berg. cap.* 27. *act. holm.* 1766. *p.* 326. *Pluk. mant.* 61. *t.* 345. *f.* 6. (Cyanus.)
   Leaves trifid-pinnate filiform, ſtem erect, heads ſolitary naked.

4. Protea patula.
   Lin. ſyſt. 136. *ed. Willd.* 507. *Thunb. prodr.* 25. *diſſ. n.* 4.
   Leaves trifid-pinnate filiform, ſtem erect, heads aggregate.

5. Protea pulchella.
   Lin. ſyſt. ed. Willd. 507. *Schrad. ſert. hannov.* 1. *faſc.* 2. *p.* 15. *t.* 7.
   Leaves bipinnate ſmooth filiform, heads terminating club-ſhaped aggregate leafleſs bracted.

6. Protea ſphærocephala.
   Lin. ſyſt. 136. *Reich.* 1. 260. *Willd.* 508. *mant.* 188. *Thunb. prodr.* 25. *diſſ. n.* 5.

Leucadendrum ſphærocephalum. *Berg. cap.* 26. *act. holm.* 1766. *p.* 327.

Anethifolius frutex africanus minor, capite tomentoſo. *Herm. afr.* 3.
   Leaves bipinnate filiform, peduncles ſhorter than the heads, calycine ſcales ovate villoſe at the baſe.

7. Protea Serraria. *Cut-leaved Protea.*
   Lin. ſyſt. 136. *Reich.* 259. *Willd.* 508. *mant.* 188. *Thunb. prodr.* 25. *diſſ. n.* 6. *Ait. kew.* 1. 125.

Leucadendron Serraria. *Lin. ſpec.* 137. *Berg. cap.* 28. *act. holm.* 1766. *p.* 327. *Burm. afr.* 264. *t.* 99. *f.* 1. (Serraria.) *Pluk. mant.* 1. *t.* 329. *f.* 1. (Abrotanoides.) *Seba, theſ.* 2. *t.* 63. *f.* 6. (Anethifolius.)
   Leaves bipinnate filiform rough-haired, peduncles longer than the heads, calycine ſcales ovate-lanceolate, rough-haired.

8. Protea triternata.
   Lin. ſyſt. 136. *Willd.* 509. *Thunb. prodr.* 25. *diſſ. n.* 7.
   Leaves bipinnate filiform ſmooth, peduncles longer than the heads, calycine ſcales lanceolate rough-haired.

9. Protea glomerata.
   Lin. ſyſt. 136. *Reich.* 1. 259. *Willd.* 509. *mant.* 187. *Thunb. prodr.* 25. *diſſ. n.* 8.

Leucadendron glomeratum. *Lin. ſpec.* 137.

L. elongatum. *Berg. cap.* 27.

Serraria fol. tenuiſſimis diviſis, capitulis tomentoſis. *Burm. afr.* 265. *t.* 99. *f.* 2.
   Leaves bipinnate filiform, common peduncle elongated, naked, pedicels longer than the heads.

10. Protea phylicoides.
   Lin. ſyſt. 137. *Willd.* 510. *Thunb. prodr.* 25. *diſſ. n.* 9.

Leucadendron

* Roxburgh, corom.

Leucadendron phylicoides. *Berg. cap.* 29. *act. holm.* 1766. *p.* 328.
Leaves bipinnate filiform, heads terminating solitary woolly.
11. Protea Lagopus,
Lin. fyst. 137. *Willd.* 510. *Thunb. prodr.* 25. *diff. n.* 10.
Leaves aggregate filiform, heads in spikes aggregate.
12. Protea spicata. *Spiked Protea.*
Lin. fyst. 137. *Reich.* 258. *Willd.* 511. *mant.* 187. *Thunb. prodr.* 25. *diff. n.* 11.
Leucadendron spicatum. *Berg. cap.* 25. *act. holm.* 1766. *p.* 326.
Leaves bipinnate filiform, heads in spikes distinct.
13. Protea Sceptrum.
Lin. fyst. 137. *Willd.* 511. *Thunb. prodr.* 25. *diff. n.* 12.
P. Sceptrum Gustavianum. *Lin. suppl.* 116. *Sparm. act. holm.* 1777. *p.* 55. *f.* 1.
Lower leaves bipinnate, upper trifid and entire.

2. Toothed: *with toothed callous leaves.*

14. Protea crinita.
Lin. fyst. 137. *Willd.* 511. *Thunb. prodr.* 25. *diff. n.* 13.
P. crinifiora. *Lin. suppl.* 117.
Leucadendron oleæfolium. *Berg. cap.* 15. *act. holm.* 1766. *p.* 320.
Leaves five-toothed smooth, stem erect, heads two or three terminating.
15. Protea Conocarpa. *Tooth-leaved Protea.*
Lin. fyst. 137. *Willd.* 512. *Thunb. prodr.* 25. *diff. n.* 14. *Ait. kew.* 1. 125.
Leucadendron Conocarpodendrum. *Lin. spec.* 136. *Berg. act. holm.* 1766. *p.* 321. *Pluk. phyt. t.* 200. *f.* 2.
Conocarpodendron fol. crasso, nervo lanuginoso, supra crenato ibique limbo rubro, flore aureo, cono facile deciduo. *Boerh. lugdb.* 2. 196. *ic.*
Scolymocephalus africanus latifolius lanuginosus, fol. in summitate crenatis. *Herm. afr.* 20. *Raii dendr.* 9.
Conophorus capitis bonæ spei fol. in summo dentato. *Raii app.* 240. *Petiv. mus.* 240.
Leaves five-toothed smooth, stem erect, head terminating.
16. Protea elliptica.
Lin. fyst. 137. *Willd.* 512. *Thunb. prodr.* 26. *diff. n.* 15.
Leaves elliptic three-toothed smooth, stem erect, head terminating.
17. Protea Hypophylla.
Lin. fyst. 137. *Willd.* 513. *Thunb. prodr.* 26. *diff. n.* 16.
P. Hypophyllocarpodendrum. *Lin. mant.* 191. *Reich. fyst.* 1. 265. *hort. cliff.* 29.
Leucadendron Hypophyllocarpodendrum. *Lin. spec.* 136. *Berg. cap.* 16. *act. holm.* 1766. *p.* 321. *Pluk. mant. t.* 440. *f.* 3.
Conocarpodendron fol. rigido angusto apice tridentato rubro, flore aureo. *Boerh. lugdb.* 2. 198. *ic.*
Scolymocephalos fol. angustis, in summitate tridentatis. *Raii dendr.* 9.
Leaves three-toothed smooth directed one way, stem decumbent, head terminating.
18. Protea cucullata.
Lin. fyst. 157. *Reich.* 1. 261. *Willd.* 514. *Thunb. prodr.* 26. *diff. n.* 17.
Leucadendron cucullatum. *Lin. spec.* 136. *Berg. cap.* 14. *act. holm.* 1766. *p.* 320. *Pluk. phyt. t.* 304. *f.* 6.
Hypophyllocarpodendron fol. inferioribus apice trifido rubro, superioribus penitus rubris glabris. *Boerh. lugdb.* 2. 206. *ic.*
Scolymocephalos africana, fol. angustis brevioribus, tribus in summitate denticulis, capitulis foliosis interceptis. *Herm. afr.* 20.
Leaves three-toothed smooth, heads lateral.
19. Protea tomentosa.
Lin. fyst. 138. *Willd.* 514. *suppl.* 118. *Thunb. prodr.* 26. *diff. n.* 18.
Leaves three-toothed tomentose.

20. Protea heterophylla.
Lin. fyst. 138. *Willd.* 515. *Thunb. prodr.* 26. *diff. n.* 19.
Leaves three-toothed and entire, stem decumbent.

3. Acerose: *with filiform awl-shaped leaves.*

21. Protea pinifolia. *Pine-leaved Protea.*
Lin. fyst. 138. *Reich.* 1. 258. *Willd.* 515. *mant.* 187. *Thunb. prodr.* 26. *diff. n.* 20.
Leucadendron pinifolium. *Lin. mant* 36.
Aulax pinifolia. *Berg. cap.* 33.
Pini foliis planta africana, cyperi capitulis. *Herm. afr.* 18.
Pini folio planta capensis, floribus spicatis. *Petiv. icill.* 47.
Leaves filiform, flowers in racemes not calycled smooth.
22. Protea racemosa. *Downy-flowered Protea.*
Lin. fyst. 138. *Reich.* 1. 258. *Willd.* 515. *mant.* 187. *hort. cliff.* 496. *Thunb. prodr.* 26. *diff. n.* 21.
Leucadendron racemosum. *Berg. cap.* 23. *act. holm.* 1766. *p.* 325.
Leaves filiform, flowers in racemes calycled tomentose.
23. Protea incurva.
Lin. fyst. 138. *Willd.* 516. *Thunb. prodr.* 26. *diff. n.* 22. *t.* 3. *f.* 2.
Leaves filiform incurved smooth, heads raceme-spiked tomentose.
24. Protea caudata.
Lin. fyst. 138. *Willd.* 516. *Thunb. prodr.* 26. *diff. n.* 23. *t.* 2. *f.* 3.
Leaves filiform rough-haired, heads subsessile in spikes.
25. Protea bracteata.
Lin. fyst. 138. *Willd.* 517. *suppl.* 118. *Thunb. prodr.* 26. *diff. n.* 24. *t.* 1. *f.* 2.
P. cancellata. *Lin. fyst. Reich.* 1. 270.
Leucadendron cancellatum. *Lin. spec.* 134. *Berg. act. holm.* 1766. *p.* 326.
Lepidocarpodendron fol. angustissimis graminеis, fructu cancellato, femine coronato. *Boerh. lugdb.* 2. 193. *ic.*
Scolymocephalus africanus foliis rosmarini acutis. *Herm. afr.* 20. *Raii dendr.* 10.
Leaves filiform-channelled, head terminating, bractles multifid.
26. Protea comosa.
Lin. fyst. 138. *Willd.* 517. *Thunb. prodr.* 26. *diff. n.* 25.
Lower leaves filiform, upper lanceolate, head terminating.
27. Protea purpurea.
Lin. fyst. 138. *Reich.* 1. 269. *Willd.* 518. *mant.* 195. *Thunb. prodr.* 26. *diff. n.* 26.
Leucadendron proteoides. *Lin. spec.* 134. *Berg. cap.* 14. *act. holm.* 1766. *p.* 326.
Leaves linear recurved, heads terminating drooping, stem decumbent.
28. Protea prolifera.
Lin. fyst. 138. *Willd.* 518. *suppl.* 118. *Thunb. prodr.* 26. *diff. n.* 27. *t.* 4. *f.* 5.
Leaves awl shaped appressed, stem proliferous.
29. Protea corymbosa.
Lin. fyst. 139. *Willd.* 518. *Thunb. prodr.* 26. *diff. n.* 28. *t.* 2. *f.* 1.
P. bruniades. *Lin. suppl.* 117.
Leucadendron corymbosum. *Berg. cap.* 21. *act. holm.* 1766. *p.* 326.
Leaves linear-subulate appressed, branchlets in whorls subfastigiate.
30. Protea nana.
Lin. fyst. 139. *Willd.* 519. *Thunb. prodr.* 26. *diff. n.* 29.
P. roscida. *Lin. mant.* 189. *Lin. fyst. Reich.* 1. 261.
Leucadendron nanum. *Berg. cap.* 22. *act. holm.* 1766. *p.* 325.
Conophoros capensis pini folio. *Raii suppl. app.* 243. *Petiv. gaz. t.* 25. *f.* 7.
Leaves linear-subulate, head terminating, calyx coloured.
31. Protea lanata.
Lin. fyst. 139. *Willd.* 519. *Thunb. prodr.* 26. *diff. n.* 30. *t.* 3. *f.* 1.
Leaves three-sided appressed, head terminating woolly.

4. Linear: *with linear leaves.*

§2. Protea torta.
Lin. fyſt. 139. *Willd.* 519. *Thunb. prodr.* 26. *diff. n.* 31.
Leaves linear oblique callous.

33. Protea alba.
Lin. fyſt. 139. *Willd.* 520. *Thunb. prodr.* 26. *diff. n.* 32.
Leaves linear ſilky tomentoſe.

5. Lanceolate: *with elliptic and lanceolate leaves.*

34. Protea aulacea. *Widow-wail leaved Protea.*
Lin. fyſt. 139. *Willd.* 520. *Thunb. prodr.* 26. *diff. n.* 33. *t.* 2. *f.* 2. *Ait. kew.* 1. 126.
Leaves linear-ſpatulate ſmooth, flowers in racemes not calyceled.

35. Protea umbellata. *Umbelled Protea.*
Lin. fyſt. 139. *Willd.* 520. *Thunb. prodr.* 26. *diff. n.* 34. *Ait. kew.* 1. 126.
Leaves linear-ſpatulate ſmooth, heads terminating, bractes multifid.

36. Protea linearis. *Linear-leaved Protea.*
Lin. fyſt. 139. *Willd.* 521. *Thunb. prodr.* 26. *diff. n.* 35. *t.* 4. *f.* 2. *Ait. kew.* 1. 127.
Leaves linear-ſpatulate ſmooth, head terminating tomentoſe.

37. Protea cinerea. *Gray Protea.*
Ait. kew. 1. 127. *Lin. ſpec. ed. Willd.* 521.
P. proſtrata. *Thunb. prodr.* 27 ?
Leaves linear-wedge-ſhaped ſilky, head terminating ſilky.

38. Protea Scolymus. *Small ſmooth-leaved Protea.*
Lin. fyſt. 139. *Willd.* 522. *Thunb. prodr.* 26. *diff. n.* 36.
P. ſcolymocephala. *Lin. fyſt. ed. Reich.* 1. 271.
Leucadendron ſcolymocephalum. *Lin. ſpec.* 135. *Berg. act. holm.* 1766. *p.* 323.
Lepidocarpodendron acaulon, &c. *Boerh. lugdb.* 2. 192. *ic.*
Scolymocephalus africanus, &c. *Raii hiſt.* 3. 10.
Leaves lanceolate acute ſmooth, head terminating round ſmooth.

39. Protea abyſſinica.
Lin. ſpec. ed. Willd. 522.
Gaguedi. *Bruce itin.* 5. *app.* 52. *ic.*
Leaves lanceolate attenuated at the baſe blunt, head terminating hemiſpherical.

40. Protea mellifera. *Honey-bearing red barked Protea.*
Lin. fyſt. 139. *Willd.* 522. *Thunb. prodr.* 26. *diff. n.* 37. *Curt. magaz.* 346.
P. repens. *Lin. mant.* 189. *fyſt. ed. Reich.* 1. 262.
Leucadendron repens α. *Lin. ſpec.* 135.
Lepidocarpodendron fol. anguſtis brevioribus ſalignis, calycis ſquamis elegantiſſime ex roſeo aureo albo atro-rubro variegatis, florum plumis albis. *Boerh. lugdb.* 2. 187. *ic.*
Scolymocephalus africana, fol. anguſtis villoſis, cono mellifero. *Raii hiſt.* 3. 9.
Leaves lanceolate-elliptic ſmooth, head terminating oblong ſmooth.

41. Protea repens. *Creeping Protea.*
Lin. fyſt. 139. *Willd.* 523. *Thunb. prodr.* 26. *diff. n.* 38.
P. repens β. *Lin. fyſt. ed. Reich.* 1. 262.
Leucadendron repens β. *Lin. ſpec.* 135.
Lepidocarpodendron fol. longiſſimis anguſtiſſimis fructum elegantiſſime ex rubro flavo & albo variegatum ſuccingentibus, radice repente. *Boerh. lugdb.* 2. 190. *ic.*
Leaves lanceolate elliptic ſmooth, head ovate ſmooth, ſtem decumbent very ſhort.

42. Protea plumoſa. *Feather-flowered Protea.*
Ait. kew. 1. 127. *Lin. ſpec. ed. Willd.* 524.
Leaves lanceolate-wedge-ſhaped hoary, head terminating oblong, petals ſmooth beneath, hairy with very long hairs above.

43. Protea obliqua. *Oblique-leaved Protea.*
Lin. fyſt. 140. *Willd.* 524. *ſuppl.* 117. *Thunb. prodr.* 27. *diff. n.* 39.
Leaves linear-lanceolate ſmooth callous oblique, head cauline terminating.

44. Protea parviflora. *Small-flowered Protea.*
Lin. fyſt. 140. *Reich.* 1. 270. *Willd.* 524. *mant.* 195. *Thunb. prodr.* 27. *diff. n.* 40. *t.* 4. *f.* 1.
Leaves elliptic obtuſe callous oblique, heads ſmooth at the ends of the branchlets.

45. Protea pallens. *Pale Protea.*
Lin. fyſt. 140. *Reich.* 1. 267. *Willd.* 524. *mant.* 193. *Thunb. prodr.* 27. *diff. n.* 41.
P. conifera β, γ, δ, ε. *Lin. ſpec.* 138.
Conocarpodendron. *Boerh. lugdb.* 2. 197. *ic.* & 200. *ic.* & 203. *ic.* & 204. *ic.*
Leaves lanceolate attenuated at the baſe ſmooth acute callous, head terminating involucred, involucre long pale.]

46. Protea conifera. *Cone-bearing Protea.*
Lin. ſpec. 138. α. *fyſt.* 140. *Willd.* 525. *mant.* 193. *Thunb. prodr.* 27. *diff. n.* 42.
P. ſaligna. *Lin. mant.* 194. *fyſt. ed. Reich.* 1. 267. *hort. cliff.* 29.
Leucadendron ſalignum. *Berg. cap.* 17. *act. holm.* 1766. *p.* 303.
Scolymocephalus africana fol. brevioribus, in tubercula definentibus. *Herm. afr.* 20.
Thymelæa capitata ſ. julifera anguſto ſalicis folio. *Pluk. mant.* 181. *t.* 229. *f.* 6.
Frutex æthiopicus conifer, fol. Cneori, Salici æmulus. *Breyn. cent.* 21. *t.* 9.
Leaves lanceolate attenuated at the baſe ſmooth acute callous, head terminating involucred, involucre long acute concolor.

[47. Protea Leviſanus. *Branching Protea.*
Lin. fyſt. 140. *Reich.* 1. 268. *Willd.* 526. *mant.* 194. *Thunb. prodr.* 27. *diff. n.* 43.
P. fuſca. *Lin. ſpec.* 1. 95.
Brunia Leviſanus. *Lin. ſpec.* 2. 289. *Burm. afr.* 267. *t.* 100. *f.* 2.
Leucadendron Leviſanus. *Berg. cap.* 20. *act. holm.* 1766. *p.* 324.
Leviſanus capenſis ſerpilli folio. *Petiv. gaz. t.* 5. *f.* 7.
Conocarpodendron fol. ſubrotundis breviſſimis, &c. *Boerh. lugdb.* 2. 202. *ic.*
Chryſanthemum conyzoides, &c. *Pluk. mant. t.* 343. *f.* 9.
Leaves obovate bluntly acuminate imbricate ſmooth, ſtem hairy, the head having a blunt longer involucre.

48. Protea ſtrobilina. *Obtuſe-leaved Protea.*
Lin. fyſt. 140. *Reich.* 1. 266. *Willd.* 527. *mant.* 192. *Thunb. prodr.* 27. *diff. n.* 44. *Schraid. ſert. hanov.* 1. *faſc.* 1. *p.* 7. *t.* 1.
Conocarpodendron acaulon, &c. *Boerh. lugdb.* 2. 201. *ic.*
Leaves elliptic-oblong retuſe-callous ſmooth, head terminating ſmooth.

49. Protea imbricata. *Imbricate-leaved Protea.*
Lin. fyſt. 140. *Willd.* 527. *ſuppl.* 116. *Thunb. prodr.* 27. *diff. n.* 45. *t.* 5. *f.* 2.
Leaves lanceolate ſmooth ſtriated imbricate, head terminating.

50. Protea ſericea. *Silky Protea.*
Lin. fyſt. 140. *Willd.* 528. *ſuppl.* 118. *Thunb. prodr.* 27. *diff. n.* 46.
Leaves lanceolate ſilky, branches filiform, ſtem decumbent.

51. Protea ſaligna. *Willow-leaved Protea.*
Lin. fyſt. 140. *Willd.* 528. *Thunb. prodr.* 27. *diff. n.* 47. *Pluk. mant.* 181. *t.* 229. *f.* 4.
Leaves lanceolate ſilky, ſtem ſtrubby, heads oblong involucred.]

52. Protea argentea. *Silvery Protea.*
Lin. ſpec 137. *fyſt.* 141. *Reich.* 1. 268. *Willd.* 529. *mant.* 194. *hort. cliff.* 29. *Gærtn. fruct.* 1. 23. *Thunb. prodr.* 27. *diff. n.* 48.
Leucadendros africana arbor tota argentea ſericea, fol. integris. *Pluk. phyt. t.* 200. *f.* 1.
Argyrodendros afr. fol. ſericeis & argenteis. *Comm. hort.* 2. 51. *t.* 26. *Raii dendr.* 9.
Conocarpodendron fol. argent. ſeric. latiſſimis. *Boerh. lugdb.* 2. 195. *ic.*
Globularia afr. fruteſcens thymelææ folio lanuginoſo. *Tournef. inſt.* 467.
Frutex æthiopicus conifer, fol. Cneori lanuginoſis ſalici æmulis. *Breyn. prodr.* 2. 49.
Arbor ferens folia argentea. *Zanon. hiſt. ed.* 1. 24.
Leaves lanceolate ſilvery-tomentoſe ciliate, ſtem arboreous, heads globular.

6. Oblong:

6. Oblong: *with oblong ovate leaves.*

[53. Protea acaulis. *Stemleſs Protea.*
Lin. ſyſt. 141. *Reich.* 1. 270. *Willd.* 529. *Thunb. prodr.* 27. *diff. n.* 49.
Leucadendron acaulon. *Lin. ſpec* 135.
Lepidocarpodendron acaulon. *Boerh. lugdb.* 2. 191. *ic.*
Scolymocephalus africanus lauri folio & procumbens. *Raii hiſt.* 3. 9.
Leaves oblong ſmooth, head globular ſmooth, ſtem decumbent very ſhort.
54. Protea myrtifolia. *Myrtle-leaved Protea.*
Lin. ſyſt. 141. *Willd.* 530. *Thunb. prodr.* 27. *diff. n.* 50.
Leaves oblong ſmooth, heads terminating aggregate.
55. Protea grandiflora. *Great-flowered Protea.*
Lin. ſyſt. 141. *Willd.* 530. *Thunb. prodr.* 27. *diff. n.* 51.
Leaves oblong veined ſmooth, head hemiſpherical ſmooth, ſtem arboreous.
56. Protea glabra. *Smooth Protea.*
Lin. ſyſt. 141. *Willd.* 530. *Thunb. prodr.* 27. *diff n.* 52.
Leaves oblong veinleſs ſmooth, head hemiſpherical ſmooth, ſtem ſhrubby.
57. Protea ſpecioſa. *Handſome Protea.*
Lin. ſyſt. 141. *Reich.* 264. *Willd.* 631. *mant.* 191. *Thunb. prodr.* 27. *diff. n.* 53.
P. Lepidocarpodendron. *Lin. mant.* 190.
Leucadendron Lepid. *Lin. ſpec.* 134. *Berg. act. holm.* 1766. *p.* 322.
Lepidocarpodendron. *Boerh. lugdb.* 2. 185. 186. 188. 189. *ic.*
Scolymocephalus africana fol. longis glabris, cono ſericeo, ſquamis rubiginea villoſa criſta ornatis. *Raii hiſt.* 3. 9.
Leaves oblong ſmooth, head oblong, calycine ſcales bearded at the tip.
58. Protea totta. *Upright ſmooth Protea.*
Lin. ſyſt. 141. *Reich.* 1. 265. *Willd.* 532. *mant.* 191. *Thunb. prodr.* 532. *diff. n.* 54.
Leaves ovate ſmooth callous, head ovate, corollas cylindrical rough-haired.
59. Protea hirta. *Hairy Protea.*

Leaves cordate.

DESCRIPTIONS, *&c.*

Theſe are beautiful elegant Shrubs; natives of the Cape of Good Hope. They have alternate leaves, which by their different forms have afforded ſeven ſubordinate diviſions of the numerous ſpecies. Flowers in ſome diſtinct, in ſpikes, perhaps monoecous, ſome of them being abortive; but in the greater part hermaphrodite, aggregate above a common receptacle, which is naked or elſe covered either with hairs or ſmall ſcales, ſurrounded with ſcales imbricate and forming a ſtrobile, ſometimes ſeparating the flowers, ſometimes only encircling the aggregate of flowers. Heads terminating or ſometimes but rarely axillary[1].

The celebrated Boerhaave was the firſt who made this fine genus much known, in his catalogue of the Leyden garden publiſhed in 1720, wherein he deſcribed and figured twenty-four ſpecies, under the ſeſquipedalian names of *Lepidocarpodendron*, *Conocarpodendron*, and *Hypophyllocarpodendron*. Royen (in 1740) has only twenty-one ſpecies, ſome of Boerhaave's being only varieties. He diſcarded his maſter's long names, and adopted the more elegant ones of Linnæus. Only two of theſe ſpecies were cultivated in the Leyden garden; the reſt were known no farther than by dried ſpecimens.] Mr. Miller had three ſorts growing in the Chelſea garden, but one of them was loſt in 1768. [The catalogue of the Royal botanic garden at Kew, publiſhed in 1789, enumerates twenty-four ſpecies as growing there. We owe our preſent more accurate knowledge of this genus to the indefatigable pains of the Chevalier Thunberg, who has deſcribed moſt of the ſpecies in his monograph or diſſertation, from which the following deſcriptions will be chiefly taken.

1. Stem filiform, angular, little branched, ſmooth, blood-red, a foot high. Branches at the top of the ſtem, about four, alternate, reſembling the ſtem. Leaves ſimply trifid, directed one way, erect, ſmooth, remote, a finger's length, longer than the internodes; pinnas in the middle of the leaf oppoſite, like the leaf, a little ſhorter than the middle lobe. Head of flowers at the end of the ſtem and branches, the ſize of a large pea. Common calyx imbricate, ſmooth, with ovate, acute ſcales. Corolla ſilky.

2. The whole, except the calyx, ſmooth. Stem round, purple, a foot high and more. Leaves ſcattered, glandular at the tip, the lower pinnate, the upper trifid, erect: pinnas oppoſite, about three pairs, gradually diminiſhing from an inch in length. Heads of flowers terminating, peduncled. Peduncles ſeveral, alternate, from erect ſpreading, one-flowered, unequal, from an inch to a hand in length. Bractes at the bottom of the peduncles, ſcattered, lanceolate; above aggregate, fencing the flowers, larger, oblong, all acute, quite entire, membranaceous, purpliſh, an inch long. Calyx imbricate; ſcales lanceolate, membranaceous, ſmooth, ciliate, eſpecially towards the top, with long, yelloviſh hairs.

3. Stem round, ſimple or branched, ſmooth. Branches in a ſort of whorl, like the ſtem, unequal. Leaves ſimply trifid, or ſometimes twice trifid, acute, ſmooth, frequent, erect, an inch long and more; pinnas oppoſite. Head the ſize of a hazel nut. Common calyx imbricate, ferruginous, ſmooth: ſcales lanceolate, the upper ones ciliate, with white hairs. Corolla purpliſh within, all woolly without with long white hairs.

4. Stem filiform, ſmooth, with branches in umbels, ſmooth or pubeſcent, unequal, ſpreading. Leaves trifid-pinnate, ſometimes bipinnate, ſmooth, callous-acute. Heads of flowers aggregate at the ends of the

[1] Juſſieu gen.

branches, the ſize of a pea. Calycine ſcales ovate, acuminate, ſmooth. Corollas ſnow-tomentoſe [m].

5. This is very diſtinct from all the reſt in its club-ſhaped heads, aggregate in whorls at the ends of the branches. It is a native of New Holland [n]; the reſt grow at the Cape of Good Hope.

6. Stem round, flexuoſe, erect, rigid, duſky-purple, ſimple, above wholly covered with leaves, below naked. Leaves flexuoſe, ſmooth; pinnas about four, oppoſite; pinnules alternate, at top acute with ruſeſcent glands. Heads peduncled, aggregate, almoſt the ſize of a hazel nut. Peduncles ruſeſcent, rough-haired, one-flowered, ſhorter by half than the head. Calycine ſcales ruſeſcent. Corolla ſilvery with long imbricate hairs.

7. Stem flexuoſe, erect, purple, ſmooth, two feet high and more. Branches alternate, flexuoſe, filiform, ſubfaſtigiate. Leaves longer than the internodes: pinnas about three, oppoſite; pinnules alternate, glandular-acute. Heads faſtigiate, aggregate, the ſize of a pea; on villoſe peduncles. Common calyx many-leaved, rough-haired, very ſhort, with lanceolate ſcales. Corolla rough-haired on the outſide.

It varies with all the leaves ſmooth; with the lower leaves ſmooth, and the upper rough-haired; with the lower leaves rough-haired, and the upper ones very hirſute [o].

Introduced in 1786, by Mr. Francis Maſſon [p].

8. Stem ſomewhat angular, flexuoſe at top, ſimple, ſmooth, a foot and half high. Leaves triternate; pinnas oppoſite, acute, glandular at the top; pinnules alternate. Heads aggregate, the ſize of a large pea; on alternate, tomentoſe, flexuoſe, drooping peduncles, one-flowered and two-flowered; with a ſmooth bractæ at the baſe. Corolla woolly with ſilvery hairs.

9. Stem round, ſmooth. Leaves aggregate at the top, ſmooth; pinnas about four, with ruſeſcent-callous tips; pinnules two alternate. Common peduncle ſingle; ſometimes ſeveral from the top of the ſtem: proper peduncles at the top of the common peduncle, alternate, one or two-flowered. Bractes awl-ſhaped, ſmooth, under the peduncles. Calycine ſcales ovate acute, ſmooth. Corolla hirſute on the outſide.

10. Stem round, brown, ſmooth, tubercled with the remains of the fallen leaves, a foot high and more, with umbelled ſubfaſtigiate branches. Upper leaves rough-haired, lower ſmooth: pinnas about three, oppoſite; pinnules alternate, awl-ſhaped, ruſeſcent at the tip. Head ovate, larger than a hazel nut. Calycine ſcales lanceolate, rough-haired on the outſide, ſmooth within. Corolla woolly with denſe gray hairs.

11. Stem round, erect, aſh-coloured, below naked and ſmooth, at top branched. Branches in a ſort of whorl, erect, rough-haired. Lower leaves ſmooth, upper villoſe: pinnas three, oppoſite; pinnules alternate, acute, glandular at the tip, ruſeſcent, faſtigiate. Heads at the ends of the branches in ſpikes, which are ſolitary, ſeſſile, oblong, acute, villoſe with very denſe white hairs, erect, a finger's length: heads aggregate, four-flowered.

12. Stem round, purple, very finely tomentoſe, with branches four together in whorls. Leaves ſmooth, the upper ones ſilky: pinnas three, oppoſite: pinnules alternate, acute, with an oblong yellowiſh gland at the tip. Heads four-flowered. Common calyx tomentoſe, four-leaved. Corollas very finely tomentoſe at the baſe, bearded at the tip [q].

Introduced in 1786, by Mr. Francis Maſſon [r].

13. This ſpecies is ſingular for the diverſity of leaves on the branches: the lower ones are decompound, with long linear leaflets; the upper ones are almoſt wedge-ſhaped, gradually attenuated towards the inſertion, erect, channelled, ſubcucullate about the ſtem, imbricate, very ſmooth. At the end of each branchlet is a ſingle ſeſſile ſpike, with ſilvery, whitiſh flowers [s].

14. Stem round, villoſe. Leaves ſeſſile, ovate, very blunt, entire, commonly five-toothed at the top, ſometimes but ſeldom undivided and three-toothed, the teeth callous; ſmooth, villoſe at the baſe, veined. Heads aggregate, almoſt as big as a walnut. Calycine ſcales lanceolate, ſmooth within, very finely villoſe without, bearded at the tip. Corolla cylindrical, villoſe, purpliſh. It differs from P. Conocarpa in having more and ſmaller heads of flowers, the calycine ſcales lanceolate, long; the corollas ſhorter with ſhort hairs.

15. It varies with a ſmooth and a villoſe ſtem; as alſo with ſeven-toothed, five-toothed, three-toothed and undivided leaves, on different trees, and often on the ſame branch [t].

Introduced in 1774, by Mr. Francis Maſſon [u].

16. Stem flexuoſe, villoſe. Leaves ſometimes but ſeldom four-toothed. Head ſolitary, the ſize of a pear. Common calyx imbricate, tomentoſe. Corollas long, hirſute.

17. Stem ſmooth, ſimple. Leaves elliptic-lanceolate, blunt with a point, having callous teeth and no perceptible veins. Head ſolitary, the ſize of a walnut. Common calyx tomentoſe, with ovate acute ſcales. Corolla filiform, villoſe. It is diſtinct from all the other ſpecies, in its decumbent ſtem, and leaves directed one way.

18. Stem knobbed, tomentoſe, ſimple. Leaves ſeſſile, below the middle wider and ovate, above narrower, linear, three-toothed, with callous teeth, imbricate. Heads in the axils of the upper leaves, ſeſſile, five-flowered. Common calyx imbricate, little villoſe: the lower ſcales ovate, acute; the upper ones oblong, acuminate: corolla filiform, below pubeſcent, above denſely villoſe. It is eaſily diſtinguiſhed by its narrow lateral heads.

19. The whole plant is hoary-tomentoſe. Stem round, ſimple. Leaves linear, commonly three-toothed, very ſeldom five-toothed; the teeth callous. Heads ſolitary or two together, almoſt as big as a walnut. Calycine ſcales ovate, acute. Corolla very finely pubeſcent. It is eaſily known by its being tomentoſe all over. It varies with narrower and wider leaves.

20. Stem ſmooth, a foot high, branched at top. Branches alternate, divaricating, pubeſcent. Leaves oblong, attenuated below, acute, either entire or having two or three callous teeth, ſmooth. Heads ſolitary, the ſize of a hazel nut. Common calyx tomentoſe, with lanceolate ſcales ſmooth within. Corolla villoſe.

21. Stem two feet high, erect, with branches in whorls. Leaves ſlightly channelled, acute, glandular at the tip. Racemes in terminating bundles, faſtigiate. Bractes awl ſhaped. Peduncles angular, very ſhort. Common calyx none. Corolla has four linear petals. Anthers inſerted into the middle of the corolla, linear, bent round. The whole plant is ſmooth [x].

Introduced in 1780, by Mr. William Forſyth [y].

22. Stem ſmooth, three feet high, erect, branched. Leaves acute; the lower ſmooth, the upper ſilky. Racemes a finger's length. Peduncles capillary, ſmooth, one-flowered. Calyx one-flowered, three-leaved; leaflets ovate, acute, villoſe. The whole corolla hirſute with denſe wool.—This is the only ſpecies hitherto known with a one-flowered calyx; by which mark it is well diſtinguiſhed from *P. caudata* and *incurva*; ſpecies which it very much reſembles at firſt ſight [z].

Introduced in 1787, by Mr. Francis Maſſon [a].

23. Stem erect, with branches in whorls towards the top. Leaves ſcattered. Heads ſubſeſſile. Calyx four-leaved, three or four-flowered. It differs from *P. racemoſa* in not having one-flowered calyxes, and in the leaves being more incurved: from *P. caudata* in the leaves being much longer and incurved, the heads in racemes and more remote [b]. The younger leaves are pubeſcent [c].

24. Stem ſmooth, branched at top. Leaves erect, the lower ones glandular at top, the upper ones hirſute and imbricate. Spikes cylindrical, erect. Common

[m] Thunberg. [n] Willdenow. [o] Thunberg. [p] Hort. kew. [q] Thunberg. [r] Hort. kew. [s] Linn. ſuppl. [t] Thunberg. [u] Hort. kew. [x] Thunberg. [y] Hort. kew. [z] Thunberg. [a] Willdenow. [b] Hort. kew. [c] Hort. kew.

calyx four-leaved, two-flowered, ſeldom one or three-flowered. Calycine leaflets ovate, acuminate, villoſe, unequal. Corolla hirſute. It differs from *P. racemoſa* in having ſeſſile heads, the calyxes four-leaved and two or three-flowered, the ſpike of flowers long and like a ſtrobile, the leaves ſhorter, and moſtly directed one way, ſpreading at the top.

25. Stem a foot high, ſimple, ſeldom biſid, wrinkled. Leaves acute, moſtly directed one way. Head ſolitary, the ſize of a walnut. Common calyx none, but the common receptacle fenced with three-ſided leaves and pinnatifid bractes. Corolla cohering at bottom, four-cornered, four-cleft at top, with the border ſpreading, ſmooth, ſtuffed on the inſide with a denſe white pappus ſhorter than the corolla.—This ſpecies agrees with *pinifolia* and *aulacea* in having no calyx, with *umbellata* in having multifid bractes.

26. Stem erect, knobbed with fallen leaves, ſmooth, with branches four together in whorls and faſtigiate. Lower leaves blunt; incurvate-erect; upper leaves elliptic-lanceolate, blunt, with a comoſe point. Head ſolitary, the ſize of a walnut.

27. The whole of this is ſmooth. Stem very much branched, wrinkled. Branches ſubumbelled, pubeſcent. Leaves linear-ſubulate, grooved above, entire, imbricate, from ſpreading recurved. Heads ſolitary, the ſize of a pea. Common calyx imbricate, tomentoſe: the outer ſcales minute, ovate, very ſhort; the lower lanceolate, longer than the head. Corollas ferruginous, minute.

28. Stem ſmooth, ſlender, proliferous, two feet high. Branches covered with leaves; which are ſubimbricate and ſmooth. Heads in the fork and at the tops of the branches, the ſize of a pea.

29. Stem erect, four feet high, with ſubverticillate-aggregate faſtigiate branches. Leaves flat above, convex underneath, ſharpiſh, imbricate. Heads the ſize of a pea, ſolitary, at the ends of the branches and branchlets. Common calyx many-leaved, ſhorter than the corolla; which is yellow and minute. Nut obovate, compreſſed, with an acute margin, and blunt villoſe hollow top, and a white kernel, not opening. It varies with a tomentoſe calyx.

30. Stem erect, with drooping branches in threes or thereabouts. Leaves acute, ſubimbricate. Head ſolitary, the ſize of a plum. Common calyx imbricate; outer ſcales ovate, inner oblong, acute, purple, ſpreading. Corolla covered on the outſide with a golden fleece. It is immediately known by the reſemblance of the flowers to a Roſe.

31. Stem filiform, weak, ſmooth, covered with leaves. Leaves linear, flat above, convex underneath, ſharpiſh, imbricate. Head ſilky, the ſize of a walnut. Corolla woolly all over and bearded with ſilvery hairs.

32. Stem two feet high, erect, even, with branches in whorls of four, and very ſhort branchlets alſo in whorls. Leaves bluiſh, entire, from erect ſpreading. Heads at the ends of the branchlets, the ſize of a pea. Common calyx imbricate, very ſhort, tomentoſe. Corolla ſilvery.

33. The whole of this is ſilvery tomentoſe. Stem round, erect, little tomentoſe, with umbelled branches, about ſix, filiform, erect, unequal. Leaves blunt, erect-imbricate. Heads in the fork and at the tips of the branches, ſilvery-woolly all over, fenced with leaves, the ſize of a pea.

34. The whole is ſmooth. Stem erect, little branched, three or four feet high, with branches in a ſort of whorl and ſtriated. Leaves blunt with a point. Racemes terminating, ſubumbelled. Peduncles wrinkled, ſcarcely a line in length. Bracte under each peduncle, lanceolate, channelled, white, erect, the length of the peduncle and half the flower. Common calyx none. Corolla four-petalled: petals linear, acute, channelled, equal, ſmooth, white. Anthers inſerted into the middle of the petal, linear, ſpiral, white [d].

Introduced by Mr. Francis Maſſon in 1774 [a].

35. Stem two feet high, erect. Branches at bottom few, towards the top frequent, umbelled, faſtigiate. Leaves as in the preceding. Heads the ſize of a hazel nut, ſolitary, fenced with leaves and bractes. Calyx none, but bractes on the common receptacle, alternate, pinnatifid. Corolla as in *P. bracteata* [f].

Introduced in 1787, by Mr. Francis Maſſon [e].

36. Stem erect, four feet high. Branches long, ſimple, leafy, ſmooth. Leaves ſeſſile, blunt, callous at the baſe underneath, with a ruſeſcent callus at top, a little bent back at the edge, ſomewhat convex and wrinkled on the upper ſurface, concave on the lower. Head ſolitary, as big as a middling-ſized apple. Calycine ſcales wide, ovate, acute, ſmooth within, pubeſcent on the outſide, denſely tomentoſe at the baſe. Receptacle denſely white-villoſe. Tube of the corolla compreſſed: border two-parted, the ſegments linear: one of them wider and trifid; the ſtamens and reflex ſtigma are inſerted into theſe ſegments, before they are unfolded: the other one-third of the width and entire: both villoſe, ſhorter by half than the ſtyle.—This agrees with *P. conocarpa*, *totta*, &c. in having an imbricate calyx, ſhorter by half than the ſtyle [b].

Introduced by Maſſon in 1774 [i].

37. Stem ſmooth, two feet high, with branches in whorls. Leaves linear-ſpatulate, imbricate, obtuſe, ſeſſile, with a ruſeſcent callus at the top; the lower ones ſmooth, the upper covered with whitiſh ſilky hairs preſſed cloſe. Heads ſilky, the ſize of a hazel nut [k].

Introduced by Maſſon in 1774 [l].

38. Stem three feet high, erect, wrinkled, with the branches in a ſort of whorl. Leaves attenuated below, terminated by a gland. Heads ovate, fenced with leaves, the ſize of a plum. Outer calycine ſcales ovate, inner oblong, concave, blunt. Corolla purpliſh. Receptacle ferruginous-tomentoſe [m].

Introduced in 1780, by the Counteſs of Strathmore [n].

39. Stem nine feet high, and three feet in diameter. Leaves hoary. Calyx hemiſpherical, imbricate. Corolla pubeſcent. Receptacle yellow-villoſe [o].

Native of Abyſſinia, near Lamalmon [p].

As Bruce ſaw it, this tree was thick and ſtunted, with few branches. Leaves of a dead green, not unlike the Willow, alternate, ſeſſile. Calyx of many broad ſcales. In the middle of a very hot day, the flowers unbend themſelves more, the calyx ſeems to expand, and the whole flower to turn itſelf towards the ſun, in the ſame manner as the Sun-flower. When the branch is cut, the flower dries almoſt inſtantaneouſly.

40. Stem arboreous, a fathom high, erect, branched. Leaves attenuated below, bluntiſh. Head ferruginous, viſcid, the ſize of a gooſe's egg. Calyx imbricate, with the loweſt ſcales minute, ovate; the upper ones oblong, the uppermoſt lanceolate [q].

Introduced in 1774, by Mr. Francis Maſſon [r].

41. Stem ſcarcely a hand in height, with two or three branches. Leaves at the top of the ſtem in cluſters, often convolute, with a cartilaginous rugged margin. Head ſolitary, fenced with leaves, the ſize of a plum. Common calyx imbricate; the outer ſcales minute, ovate, blunt; the inner lanceolate. Corolla covered with a white pile.—This differs very widely from the preceding in having a creeping root, the ſtem very ſhort, almoſt ſimple, one-flowered, the leaves linear margined, the head ovate ſmaller, not at all viſcid [s].

42. Introduced by Maſſon in 1774 [t].

43. Stem erect, two feet high. Branches filiform, ſcattered, unequal, pubeſcent. Leaves ſeſſile, acute, ſmooth or very finely tomentoſe. Head ſolitary, the ſize of a plum. Outer calycine ſcales ovate, acute, ſmooth; the inner ones oblong, hairy.

44. Stem very much branched, three feet high, upright, with filiform rod-like branches, and alternate branchlets

[a] Thunberg. [b] Hort. kew. [c] Thunberg. [d] Hort. kew. [e] Hort. kew. [f] Thunberg. [g] Hort. kew. [h] Willdenow. [i] Hort. kew. [k] Hort. kew. [l] Willdenow. [m] Thunberg. [n] Bruce. [o] Thunberg. [p] Hort. kew. [q] Thunberg. [r] Hort. kew. [s] Willdenow. [t] Hort. kew.

branchlets towards the top of them. Leaves lanceolate, narrowed below. Heads bluntly four-cornered. Calycine ſcales imbricate in four rows, ovate, blunt, concave, ſmooth.—It varies with the ſtem and leaves ſmooth, and hoary ſubtomentoſe [x].

Introduced in 1774, by Mr. Francis Maſſon [x].

45. Stem erect, a foot high and more, with ſimple divaricating branches. Leaves ſeſſile, ſcattered, ſubdecurrent. Bractes fencing the cone, ſomewhat like the leaves, concave, erect, whitiſh with a ſpreading callous top, three times as long as the cone. Cone ovate, ſmooth, ſeſſile. Calycine ſcales ovate, ſharpiſh, concave; the lower larger and ſmooth, the upper ſilky-tomentoſe. Receptacle naked. Corolla four-petalled. Petals linear, obtuſe; claws white, villoſe, border ſpreading, yelloviſh. Anthers four, below the top of the petals, ſeſſile, ovate, twin, yellow. Germ ſuperior, two-lobed, ſmooth. Style filiform, thickened, yelloviſh, the length of the corolla. Stigma club-ſhaped, blunt, yelloviſh [y].

According to Maſſon, this is the male of *P. conifera* [z]. It was introduced by him in 1774 [a].

46. Stem erect, three feet high, with branches in whorls and ſubdivided. Leaves terminated by a concave ſmooth gland. Cone tomentoſe ovate, the ſize of a pea. In *P. pallens* the branches are ſcattered and ſimple, the leaves are more lanceolate, the cone of flowers is ſmooth, and the bractes are coloured. But in *P. conifera*, the branches are in whorls and again ſubdivided, the leaves elliptic, the cone of flowers tomentoſe, and the floral leaves concolour. Theſe were conſidered as one ſpecies by Linneus, as were alſo *mellifera* and *repens* [b].

It was cultivated in 1752, by Mr. Miller [c].

47. Stem ſhrubby, proliferous, erect, even, with ſubpubeſcent branchlets. Leaves ſpatulate, even, ſmall, ſcattered. Flowers hemiſpherical, terminating and axillary, villoſe. Involucres equal to the floſcules, very like the ſtem-leaves, and not longer [d].

Introduced in 1774, by Mr. Francis Maſſon [d].

48. Stem erect, pubeſcent. Leaves ſeſſile. Cone ſolitary, the ſize of a plum [e].

Introduced in 1774, by Mr. Francis Maſſon [e].

49. Stem erect, three feet high, with two or three filiform pubeſcent branches. Leaves ſeſſile, imbricate with a terminating gland, preſſed cloſe at the baſe, but ſpreading at the tip. Heads ſolitary, ſeldom two together, oblong, the ſize of a ſmall walnut. Calycine ſcales lanceolate, acute-glandular. Corolla wholly covered on the outſide with a yelloviſh wool.

50. Stems branched, ſmooth. Leaves ſilky-tomentoſe all over. Heads at the ends of the branches, ſeldom aggregate, ſomewhat drooping, the ſize of a ſmall pea. Calycine ſcales lanceolate, ſmooth. Corolla yellow-tomentoſe.

51. Stem four feet high, erect, naked at bottom, ſmooth. Branches alternate, cluſtered, ſhort. Leaves acute, glandular at the top, very finely ſilvery-tomentoſe. Heads at the ends of the branches, fenced with leaves, ſolitary, the ſize of a pea [f].

Introduced in 1774, by Mr. Francis Maſſon [f].]

52. This has a ſtrong upright ſtalk, covered with a purpliſh bark, dividing into ſeveral branches which grow erect. Leaves broad, ſhining, ſilvery, making a fine appearance, when the plant is intermixed with other exotics.

[It was cultivated here ſo long ſince as 1693; and flowers in auguſt [g].

53. The whole plant is ſmooth. The ſtem is only about two inches in length, and ſeldom branched. The branches are in a ſort of whorl, diffuſed, ſomewhat knobbed, wrinkled, unequal. Leaves ſcattered, terminating, attenuated below. Head ſolitary, the ſize of a walnut. Outer calycine ſcales ovate, inner oblong. Corolla hirſute.

54. Stem three feet high, erect, branched. Branches alternate or in threes, filiform, patulous, a little villoſe at the top. Leaves ſeſſile, blunt, glandular at the tip, oblique at the baſe. Heads at the ends of the branches and branchlets, ſolitary, the ſize of a pea. Outer calycine ſcales ſmaller, lanceolate, black at the tip; inner larger, ovate, blunt, ſubciliate. Corollas on the outſide white-hirſute.

55. Stem a fathom high and more, branched. Leaves ſeſſile, blunt, ſpreading. Head terminating, ſolitary, the ſize of the fiſt. Outer calycine ſcales ovate, gradually larger; inner oblong, blunt. Corolla tomentoſe-white.

This ſpecies and *P. cynaroides* are handſome with very large heads. This has lanceolate ſeſſile leaves, with a loſty arboreous branched ſtem: but *P. cynaroides* has roundiſh petioled leaves, with a low frutecſcent ſtem ſcarcely branched.

56. Stem ſmooth all over. Leaves *ſeſſile, glandular* at the tip, thick. Head terminating, ſolitary, the ſize of an apple.

57. Stem arboreſcent, villoſe, branched, erect, a fathom in height. Leaves ſubpetioled, acute, black at the tip. Head terminating, the ſize of a gooſe's egg. Calycine ſcales all ſmooth, bearded on the outſide below the tip with long black or ferruginous hairs; the outer ones ovate, the middle oblong, the inner linear-oblong, narrower below. Corolla filiform, hirſute. It varies with narrower and broader leaves; and with a black and ferruginous beard [i].

Introduced in 1786, by Mr. Fr. Maſſon [m].

58. Stem round, erect, villoſe. Leaves ſeſſile, ovate-oblong, blunt, terminated by a red gland, ſeldom three-toothed, ſmooth. Head terminating, ſolitary, the ſize of a pear. Calycine ſcales ſmooth, ovate, acute, ciliate, *many times* ſhorter than the corolla [n].

Introduced in 1774, by Mr. Fr. Maſſon [n].

59. Stem erect, villoſe, three feet high. Leaves ſeſſile, terminated by an obtuſe gland, very ſeldom ciliate and imbricate. Heads below the top, in the axils of the leaves, ſolitary, eight-flowered or thereabouts. Calycine ſcales oblong, acute, of a yelloviſh blood red, ſhining. Corollas villoſe, a little ſhorter than the calyx. Piſtils twice as long as the corolla, curved, ſmooth [o].

Introduced in 1774, by Mr. Fr. Maſſon [o].

60. Stem two feet high, villoſe, with branches in a ſort of whorl and patulous. Leaves ſeſſile, terminated by a blunt gland, tomentoſe, imbricate. Heads ſeldom ſolitary, often many aggregate, larger than a hazel nut. Calycine ſcales lanceolate, hirſute. Corolla woolly with villoſe hairs. It varies with ovate and oblong leaves [p].

Introduced in 1774, by Mr. Fr. Maſſon [p].

61. Stem a foot high, flexuoſe, pubeſcent, with branches in whorls three or four together. Leaves ovate-roundiſh, villoſe, imbricate; the lower reflex. Head at the end of the branchlets, ſolitary, drooping, the ſize of a pea. Corolla ſilvery.

62. Stem two feet high, erect, ſmooth, branched; branches by two or threes. Leaves petioled, blunt, imbricate. Petiole round, ſhorter by half than the leaf. Heads aggregate at the ends of the branches. Calyx four-leaved, tomentoſe, four-flowered. Corolla woolly.

63. Stem erect, wrinkled, ſimple, ſcarcely a foot high. Leaves ſpreading. Petiole ſemicylindrical, wrinkled, ſmooth, an inch long. Head terminating, ovate, nearly the ſize of a child's head. Calycine ſcales gradually larger, acute, tomentoſe. Corolla white-tomentoſe [q].

Introduced in 1774, by Mr. Fr. Maſſon [q].

64. Stem ſimple, decumbent, round, ſtriated, a ſpan long. Leaves alternate, ſeſſile, roundiſh, nine-nerved; the lower ones larger, the upper ones gradually ſmaller. Head almoſt radical, ovate, truncate. Calycine ſcales gradually larger, oblong, blunt. Down fencing the ſeed, purpliſh [r].

All these species are natives of the Cape of Good Hope, or the country immediately above it, except the fifth and thirty-ninth.]

PROPAGATION AND CULTURE.

These plants are too tender to live abroad through the winter in England, but some of them are hardy enough to live in a good green-house. In the summer these may be placed in the open air in a sheltered situation; for, if they are exposed to winds, the plants will be torn, and rendered unsightly, nor will they make any progress in their growth. In warm weather they must be frequently but sparingly watered, and in cold weather this must not be too often repeated, lest it should rot their fibres.

The fifty-second sort should be placed in an airy dry glass-case, where it may be protected from cold, and have as much light as possible, and in winter should have little water; this rises easily from seeds, which must be procured from the Cape of Good Hope, where it grows naturally. The seeds will sometimes remain in the ground six or eight months, and at other times the plants will appear in six weeks; therefore the best way is to sow the seeds in small pots filled with soft sandy loam, and plunge them into a moderate hot-bed; and, if the plants should not come up so soon as expected, the pots should remain in shelter till the following spring, when, if the seeds remain sound, the plants will come up. The pots in which the seeds are sown, should have but little wet, for moisture frequently causes them to rot. When the plants appear, they should not be too tenderly treated, nor should they have much wet; but in warm weather they must be exposed to the open air in a sheltered situation, and in winter protected from frost.

Many of the sorts may be propagated by cuttings, taken off in april, just before the plants begin to shoot. Plant them in small pots filled with light earth, plunge them into a moderate hot-bed, shade them from the sun, refresh them with water gently and sparingly. About midsummer, by which time they will have put out roots, shake them gently out of the pots, plant each in a separate small pot, filled with light earth, place them in a frame, and shade them till they have taken new root, gradually inure them to the open air, and treat them like the old plants.

[Since all the Proteas except two come from the same country, the above directions are in general sufficient. Several of them have not flowered in this country, and many do not perfect their seeds. These therefore can only be increased by cuttings; and some of the species are not propagated this way without difficulty.

The warmth of a common greenhouse is generally sufficient for their protection; but many of them are delicate with respect to damp, and are apt to suffer if too much crouded, or over-watered, or placed in a damp part of the house.

PROTIUM. See *Amyris*.

PROVENZALIA. See *Calla*.

PRUNELLA, (*or* Brunella, *from the German* die Braune, *a disorder in the jaws and throat, which this plant is said to cure.*)

Lin. gen. n. 735. *Reich. n.* 793. *Schreb. n.* 990. Brunella. *Tournef. t.* 84. *Juss.* 116.

Class. 14. 1. Didynamia Gymnospermia.

Nat. order of *Verticillatæ* or *Labiatæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, two-lipped, shorter than the throat, permanent. *Upper lip* flat, wider, truncate, very slightly three-toothed. *Lower lip* erect, narrower, acute, semibifid.

COR. one-petalled, ringent: *tube* short, cylindrical: *throat* oblong: *upper lip* concave, entire, nodding: *lower lip* reflex, trifid, blunt; *middle segment* wider, emarginate, serrate.

STAM. *Filaments* four, awl-shaped, forked at top; two of them a little longer than the others. *Anthers* simple, inserted into the filaments below the top, as it were on another branch.

PIST. *Germ* four-parted. *Style* filiform, with the stamens bending to the upper lip. *Stigma* bifid.

PER. none. *Calyx* closed, containing the seeds.

SEEDS four, subovate.

OBS. *The essence of the genus consists in the forked filaments, as in* Crambe.

ESSENTIAL CHARACTER.

Filaments forked, with an anther on one of the forks. *Stigma* bifid.

   Leaves lanceolate quite entire sessile, stem erect.

DESCRIPTIONS, &c.

1. Root perennial (according to Mr. Curtis, annual) very fibrous. The whole plant is thinly set with hairs; the hairs upright and white. Stem from six to twelve inches in height, upright, commonly branching from the very bottom, hairy, purplish especially towards the top. Branches in pairs at each joint, brachiate, ascending. Leaves blunttish, hairy, obsoletely toothed or repand: petioles channelled above

and hairy along the edges. Bractes reniform, acuminate, ciliate, nerved. At the top of the ſtem, and at the end of each branch is a ſubcylindrical ſpike of flowers, truncate at top, the largeſt an inch in length. Calyx ſomewhat longer than the bractes; upper lip dilate, three-toothed, having ſeven ribs; lower bifid, mucronate, each ſegment marked with three lines, and ſerrate with ſhort ſtiff hairs; the lips are purple. Corolla violet-coloured, with a white tube, and eaſily falls: then the lips of the calyx cloſe together, the better to ſecure the germ. Seeds ſmooth, brown, terminated by a white point[f].

This plant varies much in ſize. Linneus remarks, that in open expoſed ſituations it is ſhort and trailing; but when drawn up among high graſs, and eſpecially in woods, it is upright and a foot high. In the latter caſe it has a flexuoſe ſtem, branches little, and has very long internodes. The corolla varies to red, and to white.

Native of Europe in paſtures and meadows, flowering from june to auguſt. According to Linneus, kine, ſheep and goats eat it, but horſes refuſe it.

Being aſtringent, it was formerly uſed in fluxes, and in gargariſms for aphthæ and inflammations of the fauces. It was conſidered as one of the beſt vulnerary herbs, but is now out of uſe.

β. Great-flowered Self-heal differs from the common ſort in having the ſtems lower, the leaves more tender, and the flowers double the ſize[g].—The ſtems are ſcarcely a long ſpan in height, they are erect, not branched, obſoletely quadrangular, and hirſute. Leaves either entire or very thinly toothed, narrower, on longer petioles, of a brighter green, the upper ones almoſt laciniate, all more hirſute. Spike looſer, more ovate. Corollas an inch long, paler, or not of ſo deep a blue. The upper lip of the calyx is perfectly three-toothed, whereas in the common ſort it has only three ſpinules. The bractes are wider. The root is ſhorter, ſcarcely creeping[h].

The flower is ſometimes white, and it varies with laciniate leaves, which varieties differ as much from the ſpecies as the ſecond differs from the firſt. A drier ſoil ſeems to render the leaves more or leſs cut, more hairy, and frequently the corolla white[i].

Mr. Curtis cultivated it ſeveral years without diſcovering it to have the leaſt diſpoſition to vary. In july and auguſt, it puts forth its large ſhowy bloſſoms, of a fine purple colour.

Native of Auſtria, Sileſia, Dauphiné. Profeſſor Jacquin found it mixed with the *laciniata*. Villars obſerved it on high mountains, in moiſt meadows, and near water.

2. Root perennial. Stems hard, ſmall and branched, from three to ſix inches in height, but in one variety creeping on the ground. Leaves more or leſs villoſe, and more or leſs cut. Flowers not larger than thoſe of the common ſort; but more commonly white or yellow than blue or purple[k].

Native of Germany, Auſtria, Switzerland, Dauphiné, Piedmont, in the lower mountains, dry paſtures, and by the ſide of cultivated grounds.

This plant is more nearly allied to the common ſort, than that is to the *grandiflora*. This, like the *grandiflora*, is more hairy, the leaves more cut, and the flowers more frequently white, in the dry grounds where it is commonly found[l].

Linneus conſiders it as differing very little from the common ſort, and as having ſprung originally from that; the ſame ſtructure remaining, and the fructification being entirely the ſame.]—There are ſeveral varieties of it: γ has narrower leaves, cut into finer ſegments.

[It was cultivated here in 1713, and flowers from july to ſeptember[m].

3. This differs from the common ſort in having an erect ſtem, not an aſcending one, the leaves lanceolate, ſeſſile, quite entire, rugged, not ovate, petioled, ſerrate, even; the corollas four times as large with the keel of the upper lip hairy[n].]

[f] Curtis, Smith, Withering, Lightfoot. [g] Villars. [h] Krocker. [i] Villars. [k] Idem. [l] Idem. [m] Hort. kew. [n] Linn. ſyſt.

The leaves are narrower than either of the former, and are covered on both ſides with fine hairs, and have very ſhort foot-ſtalks; the ſpikes of flowers are ſlender, and the corolla of a pale blue colour.

[Stem ſtraight, firm and little branched; leaves narrow, oblong, entire, hairy; flowers large, blue or white; the upper lip is deeper, hollowed like a helmet, compreſſed by an eminence and villoſe on the outſide; the lower a little concave, cut at the edge[o].

Allioni ſays, that he found the plants removed into the garden from the county of Nice to become leſs ſtrigoſe, and to approach in habit to the common ſort. Bellardi alſo made the ſame obſervation, on ſowing the ſeeds in a garden. Hence Allioni ſuſpects very much that it is nothing more than a variety.

We have here then either four ſpecies or one ſpecies with three varieties; for *grandiflora* differs as much and is as permanent as the others.

P. hyſſopifolia is a native of the South of France and the county of Nice; and was cultivated in 1731, by Mr. Miller. It flowers from july to october[p].]

Mr. Miller enumerates four other ſorts. His fifth ſpecies *P. ſulphurea*, with ſulphur-coloured flowers, is probably a variety of the ſecond. The three others, *P. canadenſis*, n. 4. *P. caroliniana*, n. 6. and *P. Novæ Angliæ*, n. 7. are, as the names imply, natives of North America.

PROPAGATION AND CULTURE.

Sow the ſeeds in the autumn, ſoon after they are ripe; for when ſown in the ſpring, they ſeldom grow till twelve months after; if they ſucceed at all. Thin the plants where too cloſe, and keep them clean from weeds. They thrive beſt on a moiſt ſoil and in a ſhady ſituation, where they will live three or four years, but in rich land they ſeldom continue longer than two years.

[They may alſo be increaſed by parting the roots in autumn.

PRUNELLA. See *Cleonia*, *Dracocephalum*, *Ruellia*.

PRUNIFERA. See *Laurus Perſea* and *Sapindus*.]

PRUNING OF TREES. There is not any part of Gardening of more general uſe than that of Pruning, and yet it is very rare to ſee Fruit Trees ſkilfully managed. Almoſt every Gardener will pretend to be a maſter of this buſineſs, though there are few who rightly underſtand it; nor is it to be learnt by rote, but requires a ſtrict obſervation of the different manners of growth of the ſeveral ſorts of fruit trees, which muſt be differently treated, according as they are naturally diſpoſed to produce their fruit. Some ſorts produce it on the ſame year's wood, as Vines; others for the moſt part upon the former year's wood, as Peaches, Nectarines, &c. and others upon curſons or ſpurs, which are produced upon wood of three, four or five to fifteen or twenty years old, as Pears, Plums, Cherries, &c. In order to the right management of Fruit Trees, there ſhould always be proviſion made for a ſufficient quantity of bearing wood in every part of the tree; and at the ſame time there ſhould not be a ſuperfluity of uſeleſs branches, which would exhauſt its ſtrength, and cauſe it to decay in a few years.

The reaſons for pruning Fruit Trees are: firſt, to preſerve them longer in a vigorous bearing ſtate: ſecondly, to render them more beautiful to the eye: and thirdly, to cauſe the fruit to be larger and better taſted.

1. It preſerves a tree longer in a healthy bearing ſtate: for by pruning off all ſuperfluous branches, the root is not exhauſted in ſupplying ſuch as are uſeleſs, and which muſt afterwards be cut out.

2. By ſkilful Pruning, a tree is rendered much more pleaſing to the eye. But here I would not be underſtood to be an advocate for drawing a regular line along the wall, according to the ſhape which the tree is to be reduced to, and cutting all the branches, ſtrong or weak, exactly to the chalked line; the abſurdity of which practice will ſoon appear to every one who obſerves the difference of thoſe branches ſhooting, at the ſucceeding ſpring. All therefore that I mean by rendering a tree beautiful by pruning is,

[o] Villars. [p] Hort. kew.

that

that the branches ſhould be all cut according to their ſeveral ſtrengths, and nailed at equal diſtances, in proportion to the different ſizes of their leaves and fruit, and that no part of the wall (ſo far as the trees are advanced) be left unfurniſhed with bearing wood. A tree well managed, though it does not repreſent any regular figure, yet will appear very beautiful to the ſight, when thus dreſſed and nailed to the wall.

3. It is of great advantage to the fruit, for the cutting away all uſeleſs branches, and ſhortening all the bearing ſhoots according to the ſtrength of the tree, will render the tree more capable to nouriſh thoſe fruit and branches which are left remaining, ſo that the fruit will be much larger and better taſted. And this is the advantage which thoſe trees againſt walls or eſpaliers have to ſuch as are ſtandards, and are permitted to grow as they are naturally inclined; for it is not their being trained either to a wall or eſpalier which renders their fruit ſo much better than ſtandards, but becauſe the roots have a leſs quantity of branches and fruit to nouriſh, and conſequently their fruit will be larger and better taſted.

The reaſons for Pruning being thus exhibited, the next thing is the method of performing it; but this being fully handled under the ſeveral articles of the different kinds of fruit, I ſhall not repeat it again in this place, and therefore ſhall only add ſome few general inſtructions, which are neceſſary to be underſtood, in order to the right management of fruit-trees.

There are many perſons who ſuppoſe, that if their fruit-trees are but kept up to the wall or eſpalier during the ſummer ſeaſon, ſo as not to hang in very great diſorder, and in winter to get a gardener to prune them, it is ſufficient, but this is a miſtake; for the greateſt care ought to be employed about them in the ſpring, when the trees are in vigorous growth, which is the only proper ſeaſon to procure a quantity of good wood in the different parts of the tree, and to diſplace all uſeleſs branches as ſoon as they are produced, whereby the vigour of the tree will be entirely diſtributed to ſuch branches only as are deſigned to remain, which will render them ſtrong, and more capable to produce good fruit; whereas, if all the branches are permitted to remain which are produced, ſome of the more vigorous will attract the greateſt ſhare of the ſap from the tree, whereby they will be too luxuriant for producing fruit, and the greateſt part of the other ſhoots will be ſtarved, and rendered ſo weak, as not to be able to produce any thing elſe but bloſſoms and leaves, as hath been before mentioned; ſo that it is impoſſible for a perſon, let him be ever ſo well ſkilled in fruit-trees, to reduce them into any tolerable order by Winter-pruning only, if they are wholly neglected in the ſpring.

There are others who do not entirely neglect their trees during the ſummer ſeaſon, as thoſe before-mentioned, but yet do little more good to them by what they call Summer-pruning; for theſe perſons neglect their trees at the proper ſeaſon, which is in april and may, when their ſhoots are produced, and only about midſummer go over them, nailing in all their branches, except ſuch as are produced fore-right from the wall, which they cut out, and at the ſame time often ſhorten moſt of the other branches; all which is entirely wrong practice, for thoſe branches, which are intended for bearing the ſucceeding year, ſhould not be ſhortened during the time of their growth, which will cauſe them to produce one or two lateral ſhoots from the eyes below the place where they were ſtopped, which ſhoots will draw much of the ſtrength from the buds of the firſt ſhoot, whereby they are often flat, and do not produce their bloſſoms; and, if thoſe two lateral ſhoots are not entirely cut away at the Winter-pruning, they will prove injurious to the tree, as the ſhoots which theſe produce, will be what the French call water ſhoots; and in ſuffering thoſe luxuriant ſhoots to remain upon the tree until midſummer before they are diſplaced, they will exhauſt a great ſhare of the nouriſhment from the other branches (as was before obſerved;) and, by ſhading the fruit all the ſpring ſeaſon, when they are cut away, and the other branches faſtened to the wall, the fruit, by being ſo ſuddenly expoſed, will receive a very great check, which will cauſe their ſkins to grow tough, and thereby render them leſs delicate. This is to be chiefly underſtood of ſtone fruit and Grapes, but Pears and Apples being much hardier, ſuffer not ſo much, though it is a great diſadvantage to thoſe alſo to be thus managed.

It muſt alſo be remarked, that Peaches, Nectarines, Apricots, Cherries, and Plums, are always in the greateſt vigour, when they are the leaſt maimed by the knife; for where theſe trees have large amputations, they are very ſubject to gum and decay; ſo that it is certainly the moſt prudent method carefully to rub off all uſeleſs buds when they are firſt produced, and pinch others where new ſhoots are wanted to ſupply the vacancies of the wall, by which management trees may be ſo ordered, as to want but little of the knife in Winter-pruning, which is the ſureſt way to preſerve theſe trees healthful, and is performed with leſs trouble than the common method.

The management of Pears and Apples is much the ſame with theſe trees in ſummer, but in winter they muſt be very differently pruned; for as Peaches and Nectarines for the moſt part produce their fruit upon the former year's wood, therefore they muſt have their branches ſhortened according to their ſtrength, in order to produce new ſhoots for the ſucceeding year; ſo Pears, Apples, Plums, and Cherries, on the contrary, producing their fruit upon curſons or ſpurs, which come out of the wood of five, ſix, or ſeven years old, ſhould not be ſhortened, becauſe thereby thoſe buds, which were naturally diſpoſed to form theſe curſons or ſpurs, would produce wood branches, whereby the trees would be filled with wood, but never produce much fruit; and as it often happens that the bloſſom buds are firſt produced at the extremity of the laſt year's ſhoot, by ſhortening the branches the bloſſoms are cut away, which ſhould always be carefully avoided.

There are ſeveral authors who have written on the ſubject of Pruning in ſuch a prolix manner, that it is impoſſible for a learner to underſtand their meaning. Theſe have deſcribed the ſeveral ſorts of branches which are produced on fruit-trees; as wood branches, fruit branches, irregular branches, falſe branches, and luxuriant branches, all which they aſſert every perſon, who pretends to Pruning, ſhould diſtinguiſh well; whereas there is nothing more in all this but a parcel of words to amuſe the reader, without any real meaning; for all theſe are comprehended under the deſcription already given of luxuriant or uſeleſs branches, and ſuch as are termed uſeful or fruit-bearing branches; and, where due care is taken in the ſpring of the year to diſplace theſe uſeleſs branches (as was before directed,) there will be no ſuch thing as irregular, falſe, or luxuriant branches at the Winter-pruning; therefore it is to no purpoſe to amuſe people with a cant of words, which, when fully underſtood, ſignify juſt nothing at all.

But ſince I have explained the different methods of Pruning the ſeveral ſorts of fruits under the reſpective articles, I ſhall forbear repeating it again in this place, but ſhall only give ſome general hints for the Pruning of ſtandard fruit-trees, and ſo conclude.

Firſt, you ſhould never ſhorten the branches of theſe trees, unleſs it be where they are very luxuriant, and grow irregular on one ſide of the tree, attracting the greateſt part of the ſap of the tree, whereby the other parts are unfurniſhed with branches, or rendered very weak; in which caſe the branch ſhould be ſhortened down as low as is neceſſary, in order to obtain more branches, to fill up the hollow of the trees; but this is only to be underſtood of Pears and Apples, which will produce ſhoots from wood of three, four, or more years old, whereas moſt ſorts of ſtone fruit will gum and decay after ſuch amputations.

But from hence I would not have it underſtood, that I would direct the reducing of theſe trees into an exact ſpherical figure, ſince there is nothing more deteſtable than to ſee a tree (which ſhould be permitted to grow as it is naturally diſpoſed, with its branches

produced at proportionable diſtances, according to the ſize of the fruit,) by endeavouring to make it exactly regular at its head, ſo crouded with ſmall weak branches as to prevent the air from paſſing between them, which will render the trees incapable to produce fruit. All that I intend by this ſtopping of luxuriant branches, is only when one or two ſuch happen on a young tree, where they entirely draw all the ſap from the weaker branches, whereby they ſtarve them, then it is proper to uſe this method, which ſhould be done in time, before they have exhauſted the roots too much.

Whenever this happens to ſtone fruit, which ſuffer much more by cutting than the former ſorts, it ſhould be remedied by ſtopping or pinching thoſe ſhoots in the ſpring, before they have obtained too much vigour, which will cauſe them to puſh out ſide-branches, whereby the ſap will be diverted from aſcending too faſt to the leading branch (as hath been directed for wall-trees,) but this muſt be done with caution.

You muſt alſo cut out all dead or decayed branches, which cauſe their heads to look very ragged, eſpecially at the time when the leaves are upon the tree; theſe being deſtitute of them, have but a deſpicable appearance; beſides, theſe will attract noxious particles from the air, which are injurious to the trees, therefore the ſooner they are cut out the better. In doing of this you ſhould obſerve to cut them cloſe down to the place where they were produced, otherwiſe that part of the branch left will decay, and prove equally hurtful to the tree; for it ſeldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced; and, if any part is permitted to remain long uncut, does often inſect ſome of the other parts of the tree. If the branches are large which you cut off, it will be very proper, after having ſmoothed the cut part exactly even with a knife, chiſſel, or hatchet, to put on a plaſter of grafting clay, which will prevent the wet from ſoaking into the tree at the wounded part.

All ſuch branches as run acroſs each other ſhould alſo be cut out, for theſe not only occaſion a confuſion in the head of the tree, but, by lying over each other, rub off their bark by their motion, and very often occaſion them to canker, to the great injury of the tree; and on old trees (eſpecially Apples) there are often young vigorous ſhoots from the old branches near the trunk, which grow upright into the head of the trees. Theſe therefore ſhould carefully be cut out every year, leſt, by being permitted to grow, they fill the tree too full of wood; which ſhould always be guarded againſt, ſince it is impoſſible for ſuch trees to produce ſo much, or ſo good fruit as thoſe, whoſe branches grow at a farther diſtance, whereby the ſun and air freely paſs between them in every part of the tree.

Theſe are the general directions which are proper to be given in this place, ſince not only the particular methods, but alſo the proper ſeaſons for Pruning all the different kinds of fruit, are fully exhibited under their ſeveral articles.

[PRUNO AFFINIS. See *Cedrela*, *Guaiacum*, *Spiræa*.

PRUNUM. See *Averrhoa*.]

PRUNUS (*of Pliny and other Latin writers. Said to be a word of Aſiatic origin; the wild Plum, according to Galen, being called προυμνος in Aſia; from the Greek πρυμνη, which occurs in Theophraſtus.*)

Lin. gen. n. 620. *Reich. n.* 675. *Schreb. n.* 849. *Tournef. t.* 398. *Juſſ.* 341. *Gærtn. t.* 93. Armeniaca. *Tournef. t.* 399. *Juſſ.* 341. Ceraſus. *Tournef. t.* 401. *Juſſ.* 340. Lauroceraſus. *Tournef. t.* 403. Padus, *edit. pr.*

Claſſ. 12. 1. Icoſandria Monogynia.

Nat. order of *Pomaceæ*. *Roſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leaſed, bell-ſhaped, five-cleft, deciduous: *ſegments* blunt, concave.

COR. *Petals* five, roundiſh, concave, large, ſpreading, inſerted into the calyx by their claws.

STAM. *Filaments* twenty to thirty, awl-ſhaped, almoſt the length of the corolla, inſerted into the calyx. *Anthers* twin, ſhort.

PIST. *Germ* ſuperior, roundiſh. *Style* filiform, the length of the ſtamens. *Stigma* orbicular.

PER. *Drupe* roundiſh.

SEED. *Nut* roundiſh, compreſſed, with ſutures a little prominent.

Obs. Padus, *Lauroceraſus*, *Tourn.* 1—6.—Armeniaca, *Tourn.* 7, 8.—Ceraſus, *Tourn.* 9, 10. Prunus, *Tourn.* 11—13.

ESSENTIAL CHARACTER.

Cal. five-cleft, inferior. *Pet.* five. *Drupe* with a nut having the ſutures prominent.

SPECIES.

Peduncles ſolitary, leaves elliptic ſmooth, fruits pendulous on branches almoſt deſtitute of prickles.

DESCRIPTIONS, *&c.*

Linneus has united the *Bird Cherry* or *Padus*, the *Apricot*, the *Cherries*, and the common and Portugal *Laurels*, with the *Plums* in the ſame genus *Prunus*. Mr. Miller has treated on them ſeparately under *Padus*, *Armeniaca*, *Ceraſus* and *Prunus*; uniting the Laurels with *Padus*. Juſſieu ſeparates *Ceraſus* and *Armeniaca* from *Prunus*; and unites *Padus* and the *Laurels* with the former: making the difference to conſiſt only in the fruit or drupe.]

1. The common Bird Cherry riſes to the height of ten or twelve feet, and if permitted to ſtand, will have a trunk of nine or ten inches in diameter. The branches grow wide and ſcattering, and are covered with a purpliſh bark. Leaves ovate-lanceolate, alternate, ſlightly ſerrate. Flowers in long looſe bunches from the ſide of the branches. Petals white, much ſmaller than thoſe of the Cherry. Flowers ranged alternately, each on a ſmall pedicel: they have a ſtrong ſcent,

ſcent, which is very diſagreeable to moſt perſons. They appear in may, and are ſucceeded by ſmall roundiſh fruit, at firſt green, afterwards red, but when ripe black; incloſing a roundiſh furrowed ſtone or nut, which ripens in auguſt.

[The flowers are in leafy racemes below the leaves. The petals are ſerrate, as in the *Prunus virginiana*, not emarginate as in the Cherry[t].

According to Haller, it is a very leafy ſhrub, ten feet in height. Leaves ſoft and acuminate. Petals ſmall, flaccid. Stamens from twenty to thirty-three. Under each flower a wide mucronate bracte. It differs from the Cherry, in having the flowers ſolitary, the calyx ſhort neither reflex nor caducous, and the ſtone rugged.

Scopoli remarks, that the leaves are ovate and ſerrate; the peduncles ſpreading and ſimple; the petals ſubovate; the calycine teeth reflex; the ſtamens not more than twenty-four; the germ ſmooth in the villoſe bottom of the calyx.

Branches round, even. Leaves alternate, petioled, obovate, acuminate, ſerrate with the ſerratures bent in, veined, ſmooth, ſomewhat glaucous, having an acrid ſmell like Rue. Stipules intrafoliaceous, in pairs, linear, ſubciliate, deciduous. Racemes from the baſe of the year's ſhoots, ſolitary, ſimple, nodding, many-flowered, ſmooth, leafy at the baſe. Petals ſerrulate. Fruit black, having a nauſeous taſte[u].

Withering obſerves, that the calyx is finely ſerrated as well as the petals, and at the bottom within is beſet with numerous woolly hairs, and that the ſtamens are twenty-five in number.

Native of moſt parts of Europe, in woods and hedges; alſo in all the northern and temperate part of Ruſſia and all Siberia. Common in the north of England, as about Ingleborough in Yorkſhire, in woods by the Tees, at Pendeford in Staffordſhire, a few miles north of Mancheſter. In ſome parts of Norfolk, as about Watton and Dereham. In a lane between Temple Mills and Epping Foreſt. Frequent in Scotland, in woods.

The Bird Cherry, Fowl Cherry or wild Cluſter Cherry Tree, called in Scotland Hag-berry, which is commonly propagated in the nurſeries as an ornamental tree or ſhrub, grows well in woods, groves or fields, but not in a moiſt ſoil. It bears lopping, and ſuffers the graſs to grow under it. The fruit is nauſeous, but bruiſed and infuſed in wine or brandy, it gives them an agreeable flavour. A ſtrong decoction of the bark is uſed by the Finlanders to cure venereal complaints; which practice is corroborated by the teſtimony of M. Broerland in the Stockholm acts. He directs ſix ounces of the dry, or eight of the freſh bark to be boiled away in eight pints of water to four: the doſe is four ounces four times a day. It cures the ſlighter infections alone, and combined with mercury facilitates the cure in ſeverer ſtages of the diſeaſe. A decoction of the berries is ſometimes given with ſucceſs in the dyſentery. The wood being ſmooth and tough, is made into handles for knives and whips. Sheep, goats and ſwine eat it, cows are not fond of it, horſes refuſe it[x]. The berries are much ſought after by birds, and though very nauſeous are eaten by children in ſome places[m]. In Scotland they drink an infuſion of them in brandy[n].]

2. The Red Bird Cherry, commonly called in the nurſery gardens about London the Corniſh Cherry, has been confounded with the preceding, but when raiſed from ſeed it always retains a difference. It riſes with a ſtraight upright ſtem more than twenty feet high; the branches are ſhorter, and cloſer together than thoſe of the firſt, and naturally form a regular head. The leaves are ſhorter and broader, and not ſo rough. The flowers grow in cloſer ſhorter ſpikes, ſtanding more erect. The fruit is larger, and red when ripe. It flowers a little later than the firſt ſort, namely in may and june; and the fruit ripens in auguſt.

Mr. Miller ſays it grows naturally in Armenia, whence he received the ſeeds: [its native place, however is doubtful. It appears from Furber's catalogue, that it was cultivated here in 1724[o].]

3. This riſes with a thick ſtem from ten to thirty feet high, dividing into many branches, which have a dark purple bark. Leaves ovate, alternate, on ſhort foot-ſtalks, of a lucid green, ſlightly ſerrate, and continuing in verdure as late in the autumn as any of the deciduous trees. The fruit is larger than that of the preceding, is black when ripe, and is ſoon devoured by birds. The wood is beautifully veined with black and white, and will poliſh well; it is therefore frequently uſed for cabinet work; as is alſo the firſt ſort, particularly in France, where it is called *Bois de Sainte Lucie*. (See n. 29.)

[According to Linneus, this is the offspring of the common Bird Cherry, but the warts on the branches are double the ſize. There are two pairs of glands at the top of the petiole in front. The leaves are leſs netted underneath and almoſt ſmooth. The petals are orbicular, not obovate. The fruit is four times as big, not red, as Linneus ſays it is, but like the common ſort firſt green, then red and finally black[p].

Parkinſon calls it the Virginian Cherry Bay. It is a native of Virginia and other parts of North America, and was cultivated here in 1629, as appears from Parkinſon's Paradiſus[q]. Willdenow makes the *rubra* of the Kew Catalogue a variety of this; and his own *rubra* a variety of *Prunus Padus*.]

4. Branches even. Leaves leſs rigid than in the others, finely ſerrate, green on both ſides, but manifeſtly villoſe to the touch, and ending in the petiole at the baſe.

Native of North America[r].

5. This ſeems to be rather a ſhrub, if we may judge from its growth here; the ſtalk does not riſe more than three feet high, but ſends out lateral branches ſpreading on every ſide, covered with a brown bark. Leaves alternate on very ſhort foot-ſtalks, near two inches long and three quarters of an inch broad, with ſmall acute indentures on their edges; they are of a lucid green, continuing their verdure all the year.

Native of South Carolina, whence the ſeeds were ſent by the name of Baſtard Mahogany, from the colour of the wood. It never flowered with Mr. Miller. [He cultivated it in 1759, and it is now found to flower in may[s].

6. Native of the Weſt Indies[t].—Introduced from Jamaica in 1784, by Matthew Wallen, Eſq.[u]

7. Trunk covered with a gray ſmooth bark. Wood very hard and white. Leaves alternate, two inches long, one inch and a half broad near the round baſe, even, ſhining, with very few apparent veins on the ſurface, without any indentures on the edges, pointed, on a footſtalk one third of an inch in length. Flowers white, in racemes oppoſite to a leaf, according to Sloane's figure.—Native of Jamaica[x], and Hiſpaniola[y].]

8. The Portugal Laurel riſes with a ſtrong tree-like ſtem to the height of twenty feet or more, ſending out many branches on every ſide, which have a ſhining purpliſh bark. Leaves on ſhort foot-ſtalks, of a lucid green, about three inches long, and an inch and half broad in the middle; they are ſometimes ſlightly ſerrate, but generally entire. The flowers are produced in long bunches from the ſide of the branches; they are white and ſhaped like thoſe of the common Laurel. Berries oval, pulpy, at firſt green, then red, and when ripe very dark purple; ſmaller than thoſe of the Laurel, and narrower at the end; encloſing an oval ſtone, like that of the Cherry, but more pointed at the top.

This ſhrub flowers in june, and the berries ripen in october: theſe ſhould be gathered as ſoon as they are ripe, otherwiſe the birds will devour them.

The Portugal Laurel is one of the moſt beautiful evergreen ſhrubs which we have in our plantations,

[t] Linn. ſpec. [u] Smith. [x] Withering.

eſpecially

eſpecially when it is planted in a looſe moiſt ſoil. The branches covered with a bright purple bark, the ſhining evergreen leaves, and the long racemes of white flowers, all together make a fine appearance. Being rarely injured by the ſevereſt cold of our winters, there is not any ſhrub which better deſerves our care to propagate.

It was brought to England from Portugal, but whether it is a native of that country, or was introduced from ſome other, is not certain. The Portugueſe call it Azoureiro. [According to the Kew catalogue, it is a native of Portugal and Madeira; and was cultivated in 1722, by Mr. Thomas Fairchild, as appears from Knowlton's manuſcripts.

9. The Common Laurel is a ſhrub ſending off long ſpreading branches, covered with a ſmooth brown bark. Leaves elliptical or obovate, ſlightly ſerrate, alternate, upon ſtrong, ſhort foot-ſtalks. Flowers on ſhort axillary peduncles. Calyx ovate; ſegments reflex, pointed. Petals ſmall, white. Filaments about eighteen. Fruit reſembling a black cherry, both in its external and internal ſtructure [a].

It differs from the Portugal Laurel in having the twigs and petioles green, whereas in that they are reddiſh brown. The leaves are of a yelloviſh green, whereas the green on the upper ſurface is very dark in the Portugal Laurel; they are alſo much wider in proportion and elliptical, but in the preceding they are rather lanceolate; they are both toothed about the edge, but the Common Laurel more ſlightly, and the ſerratures of this are very harſh to the touch, as if they had prickles at the end; the veins are much more prominent at the back of the leaves in the Common Laurel; in the Portugal Laurel the leaves are commonly repand along the edge; but in this they are flat except that the edge is a little bent back. The leaves in both are acuminate but end bluntly, and they generally bend down at the point. The young leaves are inclined to fold together upwards, like thoſe of the Cherry, in the Common Laurel; but in the Portugal Laurel they are revolute, leaving a wide longitudinal hollow above: the old leaves are generally imperfect at the end, and in the Common Laurel are ſometimes retuſe or emarginate. The glands, which are obſolete, are placed on each ſide the midrib, about half an inch above the petiole.

It flowers in april, and is a native of the Levant, of Caucaſus, the mountains of Perſia, and the Crimea. Cluſius received it at the beginning of the year 1576 from David Ungnad, then Ambaſſador from the Emperor of Germany at Conſtantinople, and afterwards Preſident of the Council of War at Vienna, with ſome other rare trees and ſhrubs, all of which periſhed by the ſeverity of the winter, and the careleſneſs of thoſe who brought them, except this and a Horſe Cheſtnut. It was ſent by the name of *Trabiſon curmaſi*, or Date of Trebiſond.

Cluſius relates that the plant of Laurel was almoſt dead when it arrived; he put it into a ſtove exactly as it came, in the ſame tub and earth; in the april following he took it out, cut off all the dead and withered branches, and ſet it in a ſhady place; in the autumn it began to ſhoot from the root; he then removed the living part into another tub, and took great care of it: when it was advanced in growth, he laid down the branches, which took root, and he diſtributed the plants among his friends and men of eminence. Such was the origin, in Europe, of a ſhrub now become ſo common every where. Cluſius's plant died without flowering; but another which he gave to Aicholtz flowered in may 1583; and a few years afterwards with Joachim Camerarius at Nurimberg [b].

Parkinſon, in his Paradiſus, publiſhed in 1629, ſays he had a plant of the Bay Cherry, as he calls it, by the friendly gift of Maſter James Cole a Merchant of London then lately deceaſed, a great lover of all rarities, who had it growing with him at his country houſe in Highgate, where it had flowered divers times, and borne ripe fruit alſo. He deſcribes Maſter Cole's as a fair tree, which he defended from the bitterneſs of the weather, by caſting a blanket over the top thereof every year, thereby the better to preſerve it.

In the appendix to Gerarde's herbal enlarged by Johnſon, publiſhed in 1633, it is ſaid, that the Cherry Bay is now got into many of our choice Engliſh gardens, where it is well reſpected for the beauty of the leaves, and their laſting or continual greenneſs. Ray, in 1688, relates, that it was then very common in Engliſh gardens and plantations, that it flowered and fruited very well, was very patient of cold, and braved our winters even in an expoſed ſituation; that it takes readily, is of quick growth, and in a ſhort time becomes a tree of tolerable ſize [c].

Laurel leaves have a bitter ſtyptic taſte, accompanied with a flavour reſembling that of bitter almonds, or other kernels of the drupaceous fruits. The flowers alſo manifeſt a ſimilar flavour. The powdered leaves excite ſneezing, though not ſo ſtrongly as tobacco.

The kernel-like flavour which the freſh leaves impart being generally eſteemed grateful, has cauſed them to be uſed for culinary purpoſes, in cuſtards, puddings, blancmange, &c. and as the proportion of this ſapid matter of the leaf to the quantity of milk is commonly inconſiderable, probably little or no bad effect may be produced. But ſince the poiſonous quality of the Laurel is now indubitably proved, the public ought to be cautioned againſt its internal uſe.

An account in the 37th volume of the Philoſophical Tranſactions by Dr. Madden of Dublin, of two women being poiſoned by the ſimple diſtilled water of Laurel leaves, contain the firſt and principal proofs of the deleterious effects of this vegetable upon the human race.

In addition to this we may refer to the unfortunate caſe of Sir Theodoſius Boughton, whoſe death in 1780 was occaſioned by this poiſon: but in his caſe the active principle of the Laurel was concentrated by repeated diſtillations, and given to the quantity of an ounce.

To brute animals this poiſon is almoſt inſtantaneouſly mortal, as amply appears by the experiments of Madden, Mortimer, Nicholls, Langriſh, Vater, Fontana and others. Upon human ſubjects its action is much leſs powerful.

Dr. Cullen obſerves, that the ſedative power of Laurocerafus acts upon the nervous ſyſtem in a different manner from Opium and other narcotic ſubſtances, whoſe primary action is upon the animal functions; for Laurocerafus does not occaſion ſleep, nor does it produce local inflammation, but ſeems to act directly upon the vital powers. Abbé Fontana ſuppoſes that this poiſon deſtroys animal life by exerting its effects upon the blood; but the experiments and obſervations from which he deduces this opinion are evidently inconcluſive.

Though this vegetable ſeems to have eſcaped the notice of Stoerck, yet it is not without advocates for its medicinal uſe. Linneus informs us, that in Switzerland it is commonly and ſucceſsfully uſed in pulmonary complaints. Langriſh mentions its efficacy in agues; and as Bergius found bitter almonds to have this effect, we may from analogy conclude, that this power of Laurocerafus is well eſtabliſhed. Bayliſs found that it poſſeſſed a remarkable power of diluting the blood, and from experience recommended it in all caſes of diſeaſe ſuppoſed to proceed from too denſe a ſtate of that fluid; adducing particular inſtances of its efficacy in rheumatiſm, aſthma, and ſchirrous affections. Nor does this author ſeem to have been much afraid of the deleterious quality of Laurocerafus, for he directs a pound of its leaves to be macerated in a pint of water, and from thirty to ſixty drops of this liquor to be given three or four times a day [c].

10. Stem arboreous. Branches and branchlets alternate, knobbed, dotted with white, wrinkled, ſmooth. Leaves on the branchlets aggregate, ſcattered, on ſhort petioles, bluntiſh, veined, ſpreading, a finger's length. Racemes few-flowered. Drupe

[a] Woodville. [b] Cluſ. hiſt. [c] Ray, hiſt. [d] Woodville.

oblong,

oblong, the ſize of a ſmall grape. This tree is ſaid to have been introduced into Japan by the Portugueze inſtead of the Olive.

11. Stem arboreous, wholly ſmooth. Branches and branchlets alternate, erect. Leaves ſcattered, petioled, acute, ſerrate, veined, ſmooth, unequal, from an inch to two inches in length and more. Petioles erect, a line long. Flowers white, in a wide and very ſpreading panicle; in which circumſtance it differs from the Mahaleb: as alſo in having ſmaller flowers, and the leaves more oblong, attenuated below, and acutely ſerrate.—Native of Japan[a].

12. Leaves folded together, blunt, crenate. Stipules crenate, with brown teeth. Corymb convex. Bractes very ſhort, very blunt, ſerrate[c].

This is a low crooked tree. The wood is red, very hard, and ſweet-ſcented. Leaves wide and pointed, approaching to thoſe of the wild Pear. Flowers white. Fruit black, yielding a bitter purple juice, the ſtain of which is not eaſily effaced; the ſtone is ſmooth, round and a little flatted on the ſides; incloſing a bitter perfumed kernel[f]. Birds are very fond of this fruit. A fragrant and pleaſant diſtilled water is made from both leaves and flowers[g].]

The wood, on account of its agreeable odour is greatly eſteemed by the French for making cabinets and other furniture. This and the wood of the Bird Cherry are often confounded, and paſs under the appellation of Bois de Sainte Lucie, but the Bird Cherry is the true ſort. [Villars however calls the Mahaleb by this name.

Native of Germany, Switzerland, Auſtria, the South of France and Piedmont, Crim Tartary and every where on Caucaſus.—Cultivated in 1714 by the Dutcheſs of Beaufort. It flowers in april and may[b]. Ray calls it Rock Cherry.

Gerarde ſays, that "the fruit is as hard as a bead "of corall, ſomewhat round and of a ſhining black "colour, which the cunning French perfumers do "bore through, making thereof bracelets, chains, "and ſuch like trifling toys, which they ſend into "England ſmeared over with ſome odd ſweet com-"pound or other, and here ſold unto our curious "ladies and gentlewomen for rare and ſtrange Pome-"ambers, for great ſums of money."

13. The Apricock or Apricot is ſufficiently diſtinguiſhed by its broad roundiſh leaves drawn to a point at the end, ſmooth, glandular at the baſe in front, where they are ſometimes ſlightly cordate, and unequal, that is, one ſide longer than the other; the edge is finely ſerrate; the petiole is from half an inch to an inch in length, commonly tinged with red. Linneus remarks, that the vernant leaves are convoluted, that is, not folding flat together like thoſe of the Cherry, but rolling upwards more or leſs; the leaves of many Apricot trees have a diſpoſition to this at all times. The flowers are ſeſſile, white tinged with the ſame duſky red that appears on the petioles. The fruit is round, yellow within and without, firmer than Plums and moſt Peaches, incloſing a ſmooth compreſſed ſtone, reſembling that of the Plum.

Parkinſon, more than a century before Linneus affirmed, that "the Apricocke is without queſtion a "kind of Plumme. And yet," ſays he, "becauſe "of the excellency of the fruit, and the difference "therein from all other Plummes, I have thought it "meete to entreate thereof by itſelfe.

"The Apricocke riſeth up to a very great height, "having a great ſtemme or body, and likewiſe many "great armes or branches, covered with a ſmooth "barke: the leaves are large, broad, and almoſt "round, but pointed at the ends, and finely dented "about the edges: the flowers are white, as the "Plumme tree bloſſomes, but ſomewhat larger, and "rounder ſet: the fruit is round, with a cleft on the "one ſide, ſomewhat like unto a Peach, being of a "yellowiſh colour as well on the inſide as outſide, of "a firme or faſt ſubſtance, and dry not overmoiſt in "the eating, and very pleaſant in taſte, containing "within it a broad and flat ſtone, ſomewhat round "and ſmooth, not rugged as the Peach ſtone, with a "pleaſant ſweet kernell, and is ripe almoſt with our "firſt or earlieſt Plummes, and thereof it took the "name of *Præcox*."

It is not certain of what country this fruit-tree is a native. It undoubtedly came into Europe from ſome part of Aſia, and by its name of *Malus Armeniaca* was ſuppoſed to originate from Armenia. Thunberg deſcribes it as a very large, ſpreading, branching tree in Japan; Groſier ſays that it covers the barren mountains to the weſt of Pekin. Pallas, that it is commonly wild on the whole tract of Caucaſus.

Parkinſon gives us the following varieties as known in 1629.

1. The great, which ſome call the long Apricocke; the greateſt and faireſt of all the reſt.
2. The ſmaller or ſmall round Apricocke.
3. The white Apricocke, hath his leaves more folded together: it beareth but ſeldom and very few, more white, without any red when ripe.
4. The Maſculine hath a finer green leaf and thinner, and beareth very ſeldom any ſtore of fruit, which differeth in nothing from the firſt, but that it is a little more delicate.
5. The long Maſculine hath his fruit growing a little longer, and differeth in nothing elſe.
6. The Argier is a ſmaller fruit than any of the others, and yellow, but as ſweet and delicate as any of them, having a blackiſh ſtone within it, little bigger than a Lacure Cherry-ſtone; this with many other ſorts John Tradeſcante brought with him returning from the Argier voyage, whither he went voluntary with the fleete, that went againſt the Pyrates in the yeare 1620.

Rea, in 1702, has only the Algier, Maſculine, Long, White, Orange, and Great Roman.]

Miller has the following:

1. The Maſculine Apricot.
2. The Orange.
3. The Algier.
4. The Roman.
5. The Turkey.
6. The Breda.
7. The Bruſſels.

1. The Maſculine is the firſt ripe of all the Apricots; it is a ſmall roundiſh fruit of a red colour towards the ſun; as it ripens, the colour fades to a greeniſh yellow on the other ſide; it has a very quick high flavour. The tree is very apt to be covered with flowers, but as they come out early in the ſpring, they are frequently deſtroyed by the cold, unleſs the trees are covered to protect them.

2. The Orange is the next ripe; this fruit is much larger than the former, and as it ripens changes to a deep yellow colour. The fleſh being dry and not high flavoured, it is better for tarts and preſerving than for eating raw.

3. The Algier is the next in ſeaſon; this is of an oval ſhape, a little compreſſed on the ſides; it turns to a pale yellow, or ſtraw-colour, when ripe; the fleſh is high flavoured, and very full of juice.

4. The Roman is the next ripe; this is a larger fruit than the former, and not compreſſed ſo much on the ſides; the colour is deeper, and the fleſh is not ſo moiſt as the former.

5. The Turkey Apricot is yet larger than either of the former, and of a globular figure; the fruit turns to a deeper colour than the former; the fleſh is firmer, and drier than thoſe of the two preceding.

6. The Breda Apricot (as it is called from its being brought from thence into England) was originally brought from Africa; this is a large roundiſh fruit, changing to a deep yellow when ripe; the fleſh is ſoft, full of juice, and of a deep Orange colour within ſide; the ſtore is rounder and larger than any of the other ſorts: this is the beſt Apricot we have, and when ripened on a ſtandard, is preferable to all other kinds.

7. The Bruſſels is the lateſt ripe of all the Apricots, for when it is planted againſt a wall, it is generally the beginning of auguſt before it is ripe, unleſs when it

[a] Thunberg. [c] Linn. ſpec. [f] Villars. [g] Krocker. [b] Hort. kew.

is planted to a full ſouth aſpect; which is what ſhould not be practiſed, becauſe the fruit is never well taſted which grows in a warm expoſure. This fruit is of a middling ſize, rather inclining to an oval figure; red on the ſide next the ſun, with many dark ſpots, and of a greeniſh yellow on the other ſide; the fleſh is firm, and of a high flavour; the fruit often cracks before it is ripe. This is commonly preferred to the former ſort by moſt people, but when the other is planted as a ſtandard, the fruit is fuller of juice, and of a richer flavour than this.

[Duhamel enumerates ten varieties.

1. Abricot précoce, or hâtif muſqué. t. 1. Maſculine.
2. A. blanc, or A. pêche.—A variety of the foregoing.
3. A. commun. t. 2.
4. A. Angoumois. t. 3.
5. A. de Hollande, or Amande-Aveline, t. 4.
6. A. de Provence. t. 4 f. P.
7. A. de Portugal. t. 5.
8. A. violet.
9. A. Alberge.—The ſeeds of this will produce the ſame fruit, or with very little variation; and is the only one which will do ſo.
10. A de Nancy. t. 6.

The induſtry of modern gardeners is ſuch, and the love of novelty ſo great, that new varieties are continually adding to our collections of fruits. Thus among Apricots, the Maſculine is ſubdivided into the Early White and the Early Red. We have the *Temple* Apricot, ripe in the middle of auguſt. The *Moor-Park*, *Peach*, *Dunmore* or *Anſon*, a large fruit, flat-ſhaped, of a deep yellow colour, and very high flavoured, &c.

The Chineſe have a variety of double-bloſſomed Apricot-trees, which they plant on little mounts in their gardens, and have a beautiful effect in the ſpring. They have alſo dwarf trees, which are placed for ornament in their apartments, where they flower during the winter.

There is a great variety of fruiting Apricots in China: and from the wild tree, whoſe fruit has little pulp, but a large kernel, they extract a great quantity of oil, ſuperior to that produced from Walnuts. The barren mountains to the weſt of Pekin, are covered with theſe trees.

The Chineſe not only preſerve the fruit of the Apricot both wet and dry, but make lozenges from the clarified juice, which diſſolved in water, yield a cool refreſhing beverage[1].

The young ſhoots yield a fine golden cinnamon colour to wool.

It appears from Turner's herbal, which is our earlieſt botanical authority, that the Apricot was cultivated here in 1562[2]. But in the Remembrances for Maſter S. by Richard Hakluyt, 1582, it is affirmed that the Abricot was procured out of Italy by a French prieſt, one Wolfe, Gardiner to King Henry VIII.[3]

This fruit ſeems to have been known in Italy in the time of Dioſcorides under the name of *Præcocia*—Αρμενιακα, Ρωμαικη Περσικικια, which is only Præcocia in Greek characters. The modern Greeks have corrupted it to Βερικοκκια, whence the Tuſcan name *Bacocche*[4], and our Engliſh *Apricock*. It is not improbable that the fruit, when firſt introduced might be called *A Præcox*, from the Latin; and our illiterate people imagining the laſt ſyllable to be *cocks*, concluded the word to be of the plural number, and *a* not to be the article, but part of the word; and ſo pronounced it *Aprecocks*, and thence formed *Aprecock* and *Apricock*[5]. Bradley ſays, that coming from Epirus the fruits were called *Mala Epirotica*. Mortimer derives it from *apricus*. When the preſent orthography from the French *Abricot* was eſtabliſhed, I cannot preciſely ſay. I find *Apricot* ſo far back as Plat's Garden of Eden in 1660, but in no other old book. Mr. Evelyn, in his French Gardiner, 1658, and in his Kalendarium Hortenſe, follows the French orthography preciſely. Maſcall in 1575 has *Abricote* and *Abrycote*. Googe in 1577 has *Abricock* and *Abricottes*. All evidently approximating to the French. None of theſe are original works.

Gerarde, in 1597, writes *Aprecocke* or *Abrecocke*, both with and without the final *e*, and alſo *Aprecox*. Parkinſon in 1629 has *Apricockes*. And ſince that time, the prevailing orthography has been *Apricock*, till very lately. We find it ſo in the two Oxford catalogues of 1648 and 1658; in Plat's Garden of Eden, 1660, as well as *Apricot*; in Ray's Hiſtory, 1688; in Rea's Flora, 1702. Mr. Miller himſelf in 1743 followed this orthography. Profeſſor John Martyn in 1749 ſpeaks of it as being then commonly written ſo; and even in 1764, Juſtice in his Britiſh Gardener writes *Apricock*.

14. This tree differs very little from the preceding; in particular the leaves are very much alike, except that in this they are very long-pointed at the end. The flowers are as it were calycled by the bud, which conſiſts of imbricate teſtaceous ſcalelets, ciliate at the edge; but this is the caſe in our common ſort of Apricot. It grows only to the height of a man, and may perhaps only be a variety from climate and ſituation.

Native of Tranſalpine Dauria in the empire of Ruſſia, where the north ſide of the mountains in may, is covered with the purple flowers of Rhododendron dauricum; and the ſouth ſide, with the white and roſe-coloured flowers of this dwarf tree. The fruit is juiceleſs, acerb or auſterely acid, and eaſily parts in two; and contains a bitter kernel[6]. Pallas ſays that *P. Armeniaca* has a ſingle gland on the petiole, which this has not, and that the loweſt ſerrature on each ſide is often glandular.]

15. This ſhrub ſeldom riſes more than three or four feet high, and divides into many ſlender branches near the ground; theſe are covered with a reddiſh brown bark. Leaves long and narrow, whitiſh underneath and light green above. The flowers come out two or three together at each joint, the whole length of the branches, on long ſlender peduncles. Petals much narrower than thoſe of the common Cherry. Fruit red, acid. It flowers in may, and the fruit ripens in july. It was ſent to Mr. Miller from Paris, under the name of *Rogeuminier*, as it is called in Canada, where it is a native[7]. [He therefore cultivated it in 1756[8].

According to Linneus, it is a ſhrub of the ſame ſtature with *Amygdalus nana*; the root is creeping; the branches rod-like and purple; the leaves underneath glaucous or pale; the proper peduncles one-flowered by threes from the lateral buds[9].

16. The Common Cherry tree has aſh-coloured, ſhining, roundiſh branches. Leaves petioled, ovate or ovate-lanceolate, acuminate, unequally ſerrate, veined; the younger ones folded together flat and more or leſs pubeſcent underneath. Stipules toothed, glandular. Umbels leafleſs, few-flowered, nodding. Calyx reflex. Petals white. Drupe red, acid[10].

Leaves biglandular; leafing and flowering buds diſtinct, the former terminating, the latter from the ſide of the branches; ſtamens more than twenty-four or near thirty. It differs from the plum in having the ſtone nearly globular, with the kernel of the ſame ſhape[11].

Native of Aſia and Europe. It derives the Greek names Κερασος and Κερασια, the Latin *Ceraſus*, and the modern names *Cherry*, *Ceriſier*, &c. from a town in Pontus called Ceraſus, whence Lucullus is ſaid to have introduced it into Italy, after he had ſubdued Mithridates. This however muſt be underſtood of the cultivated Cherry; for the tree in its wild ſtate was in Europe antecedent to the time of Lucullus[12].

The Cherry loves a ſandy ſoil and an elevated ſituation. The gum that exſudes from it is equal to Gum Arabic. Haſſelquiſt relates, that more than one hundred men, during a ſiege, were kept alive for near two months, without any other ſuſtenance, than a little of

this

this gum taken ſometimes into the mouth, and ſuffered gradually to diſſolve. The wood is hard and tough, and uſed by the turner, and for making chairs, being ſtained to imitate mahogany. It is the original ſtock from which moſt of the cultivated ſorts are derived.

Ray mentions the common Wild Cherry with a red fruit; the leaſt wild Heart Cherry-tree, in Lancaſhire, Cheſhire and Weſtmoreland; and the wild northern Cherry-tree with ſmall late-ripe fruit, on the banks of the Tees near Bernard-caſtle in Durham.

The varieties of eatable Cherries enumerated by Parkinſon in 1629 are the following:

1. The Engliſh Cherry, red, of a middling ſize, and a pleaſant ſweet taſte, ſomewhat tart withall.
2. The Flanders Cherry, ſomewhat larger, and ſweeter, and not ſo ſour.
3. The Early Flanders, almoſt as ſoon ripe as the May Cherry, and of many falſe knaves ſold for it.
4. The May Cherry.
5. The Arch-duke's Cherry, one of the faireſt and beſt we have, red, a little more long than round, and ſomewhat pointed at the end.
6. The Ounce Cherry, or Amber: pale yelloviſh red; with a great broad leaf.
7. The great leafed: probably not different from the preceding.
8. The true Gaſcoign: late ripe, large, white ſpotted: a fit ſtock to graft May Cherries upon.
9. The Morello—(ſo called from the juice being like that of the *Morus* or Mulberry.)
10. The Hartlippe, ſo called from the place where the beſt of this kind are nurſed up, between Sittingbourn and Chatham: this is the biggeſt of our Engliſh kinds.
11. The ſmaller Laeure or Hart Cherry: blackiſh when full ripe, and ſmaller than the next.
12. The great Laeure or Hart Cherry; twice as great the former, and of a reddiſh black colour, firm and reaſonably ſweet. Some call the White (n. 8.) the White Hart Cherry.
13. The Luke Wardes: dark red.
14. The Corone: deep red. (Not our Corone.)
15. The Urinall: long and round, reddiſh.
16. The Agriott (from the French *aigre*): ſmall, deep red, late ripe: ſharp, pleaſant and wholeſome, both freſh and dried.
17. The Biguarre: pale red ſpotted with white.
18. The Morocco: big, long and round, firm, having a long dark purple ſtalk; juice blackiſh, red and pleaſant: perhaps not different from the Morello.
19. The Naples; thought to be the ſame.
20. The White Spaniſh: white with ſome redneſs, firm, late; ſtalk long and ſtone large.
21. Flanders cluſter.
22. Wild or bird's cluſter.
23. Soft-ſhelled: ſmall and red, with a tender ſtone.
24. John Tradeſcant's, commonly ſold for the Arch-duke's: large, deep-coloured and a little pointed.
25. Baccalaos or Newfoundland: ſmall and pale red.
26. Long cluſter: is *Prunus Padus*.
27. The Cullen (Cologn): dark red.
28. The great Hungarian Cherry of Zwarts, like the Morello, but larger, fairer, and bears more abundantly: deep red, very ſweet, and meaſuring four inches round.
29. The Cameleon or changeable Cherry, with fruit of many forms.
30. The great Roſe or double-bloſſomed Cherry.
31. The leſſer ditto.
32. The dwarf Cherry.
33. The great bearing Cherry of Maſter Millen: large and red; a great bearer.
34. The long finger Cherry: long and round.

Mr. Ray's catalogue in 1688, contains:

1. The May Cherry, ſo called from its being ripe in the month of may.
2. The Duke Cherry.
3. The Arch-duke Cherry.
4. The Flanders Cherry.
5. The Red Heart Cherry.
6. The Bleeding Heart.
7. The Naples.
8. The Carnation.
9. The Amber.
10. The Purple.
11. The Black Orleans.
12. The common Black Cherry.
13. Luke Ward's Cherry.
14. The Cluſter Cherry.
15. The Dwarf Cherry.
16. The Morello Cherry.

Rea in 1702 has the following—

1. The May.
2. The early Flanders.
3. The later Flanders.
4. The Flanders Cluſter.
5. The Great bearing or preſerving.
6. The Morello.
7. The Arch-duke.
8. The Carnation.
9. The Lukeward.
10. The Black Heart.
11. The Black Cherry of Orleance.
12. The Black Spaniſh.
13. The Bleeding Heart.
14. The Prince Royal.
15. The Portugal.
16. The King's.
17. Corone.
18. Biguar.
19. White Spaniſh.
20. Amber.
21. Red Heart.
22. Hungarian.
23. Ciliegi Birrieloni.
24. Dwarf.]

Mr. Miller's liſt contains—

1. The common or Kentiſh Cherry, from which he ſays it is ſuppoſed, moſt of the varieties cultivated in the Engliſh gardens have been raiſed; though he is very doubtful of it; the differences in the ſize and ſhape of their leaves, and in the ſhoots of the trees being very great.
2. The early May Cherry, which is the firſt ripe, and therefore a place may be given it, where there is room.
3. The May Duke. This ripens next: it is a larger fruit, and more valuable.
4. The Arch-duke comes after the May Duke, and if permitted to hang till it is ripe, is an excellent Cherry. It ſhould not be gathered before midſummer, and may hang a fortnight longer, even near London, where it ripens a fortnight ſooner than in places forty miles diſtant. Againſt a north wall, this fruit may be continued till auguſt.
5. The Flemiſh.
6. The Red Heart.
7. The White Heart.
8. The Black Heart.
9. The Amber Heart.
10. The Ox Heart.
11. The Lukeward. A good bearer, and a very good fruit, of a dark colour, and will do well in ſtandards.
12. The Carnation. Valuable for coming late: very firm and fleſhy, but not the beſt bearer: it will ripen very well on eſpaliers.
13. The Hertfordſhire Heart: firm and well flavoured; does not ripen earlier than the end of july or the beginning of auguſt.
14. The Morello: generally planted againſt a north wall, and uſed for preſerving; but in a better aſpect, and ſuffered to hang till ripe, is a very good fruit for the table. On a S. W. wall the fruit will ripen perfectly by the middle of auguſt.
15. The Bleeding Heart.
16. The large Spaniſh Cherry, nearly allied to the Duke, of which it ſeems to be only a variety, and ripens ſoon after it.
17. The yellow Spaniſh Cherry; of an oval ſhape and an amber colour: it ripens late, is ſweet but not of a rich flavour, and is but a middling bearer.
18. The double-flowered, propagated ſolely for ornament.

[Other varieties are continually adding to theſe, differing little from the preceding, as—

19. Harriſon's Duke Cherry.
20. Crown Heart Cherry.
21. Turkey, &c.

It is commonly aſſerted that Cherries were introduced into England in the time of Henry VIII. Mr. Gough, in his topography, ſays it is ſuppoſed that they were brought from Flanders into Kent by Richard Haines, fruiterer to that monarch. But we certainly had them ſooner. We have no proof indeed that England was indebted to the Romans for Cherries and other fruits of warmer climates; or that they were here at the time of the Norman conqueſt, or during ſome centuries after it. A diligent and ingenious antiquary has however diſcovered written evidence which clearly ſhows, that before the middle of the 15th century, the hawkers in London were wont to expoſe Cherries for ſale in the ſame manner as is now done early in the ſeaſon. Lydgate, in the following lines from his poem called *Lickpenny*, cited by Mr. Warton, in the Hiſtory of Engliſh Poets, vol. 2. p. 367. ſays

> "Hot peſcode own (one) began to cry,
> "Straberys rype, and cherries in the ryſe."

That is, remarks Mr. Warton, he cried hot peas, ripe ſtrawberries, and cherries on a *bough* or twig: *rice* or *ris*, being properly a long branch, and the word is ſtill ſo uſed in the weſt of England.

The tradition therefore reſpecting Haines's having originally planted Cherry-trees at Teynham, may either mean that he was the firſt perſon who reared a Cherry orchard, or that he firſt introduced ſome particular Cherry, perhaps that which we call the Flemiſh Cherry[a], if we had it not earlier.

It is indeed extremely improbable, conſidering the magnificence of the times, and our intimate connection with France and Flanders, from the conqueſt to the deſtructive contentions between the houſes of York and Lancaſter, that we ſhould not have imported ſuch fruits as would bear our climate from thoſe countries, unleſs they had been left us by the Romans.

The above paſſage from Lydgate carries the written evidence for the cultivation of Strawberries higher than that which has been given from Stow and Shakſpeare. What is meant by *hot peas?* Surely not hot gray peas, which were commonly cried about London during winter even in this century; for they were in a dry ſtate, and the poet would not have called them *peſcodes*, nor would he have joined them with ſtrawberries and cherries. He probably intended what we now call *Hotſpur* peas.]

17. The Black Cherry is ſuppoſed to be a native of England. It grows to be a large tree, fit for timber, and is frequently found growing as ſuch in the woods. From this the only varieties which I have ever known raiſed by ſeeds, are the Black Coroun, and the ſmall Wild Cherry; of which there are two or three varieties, differing in the ſize and colour of the fruit.

The wild Cherries are proper to plant in parks, becauſe they grow to a large ſize and make beautiful trees. In ſpring, when they are in flower, they are very ornamental; the fruit is good food for birds; and the wood is very uſeful for turners. Theſe trees will thrive in poor land better than moſt other ſorts. The French often plant them for avenues to their houſes, on poor land; they alſo cultivate them in their woods, to cut for hoops.

The ſtones are generally ſown for raiſing ſtocks, to graft or bud other Cherries upon, being of quicker growth and of longer duration.

[Dr. Withering affirms that this tree grows beſt in a rich ſoil and on the ſides of hills, unmixed with other trees; that it bears cropping, and ſuffers the graſs to grow under it.

The garden Cherry grows only about fifteen or twenty feet high, whereas this attains forty or fifty feet in height, with a more erect and lofty head.

Linneus deſcribes the leaves as having one or two glands at the top of the petiole; the umbel ſeſſile and ſubtriflorous, the flowers petioled, and the involucre four-leaved: he affirms that the flowers in this are produced from the branches of the year before; but thoſe of the preceding ſpecies from the branches of the ſame year.

But Linneus does not ſeem to have intended our wild Cherry by his *Prunus avium*, for he ſays the fruit is red; and he refers to the Heart Cherry of Ray as one of the varieties of it. John Bauhin however has four varieties of the wild Cherry, the ſmall red and black, and the more fleſhy of both colours; the laſt probably improved by culture.

The common Black Cherry is much cultivated in the Chiltern part of Buckinghamſhire, and makes a beautiful appearance in the ſpring, when the trees are in bloſſom at the ſame time that the Beech is leafing. In Suffolk it abounds about Polſtead and is commonly called the Polſtead Cherry. In that county the wild Cherries are called *Merries*, from the French *Meriſe*. The *Corone* or *Coroun* Cherry, which is the higheſt improvement of this, is common in Hertfordſhire and about Bergh-Apton in Norfolk.

After all, I can ſcarcely think that the *Prunus avium* is ſpecifically diſtinct from the *Prunus Ceraſus*.

The former grows to a conſiderable ſize: Mr. Evelyn mentions one that held above eighty-five feet in height; it is then fit to make chairs and ſtools with, cabinets, tables, eſpecially the redder ſort, which will poliſh well; alſo pipes and muſical inſtruments. Willdenow ſeparates not only the *Prunus avium* but alſo the *Ceraſus pumila*, under the name of *Pr. Chamæceraſus*, that being the title which Cluſius has given it. Pallas's *Pr. fruticoſa* is this, or a variety of it, differing only in the ſize of the leaves, flowers and fruit. Jacquin has figured the Auſtrian tree in *ic. rar.* 1. 90. and deſcribed it in *Collect.* 1. 133. Pallas ſays it is a ſhrub often ſcarcely two feet, but ſometimes four feet in height; that however cultivated it never becomes a tree; and that the leaves are of a hardiſh ſubſtance; in ſhort, that it differs from the common Cherry, as the dwarf Almond does from the common ſort.

18. This has the appearance of *P. Ceraſus*, but the branchlets have whitiſh dots ſcattered over them, as in *P. virginiana*. It has the leaves of *P. Ceraſus* lanceolate-ovate, ſerrulate, even, with two glands at the baſe often red. Umbels ſeſſile. Flowers ſmaller than thoſe of *P. Ceraſus*[e]. Willdenow has deſcribed it under the name of *P. lanceolata*.

Native of North America. Introduced in 1773, by Meſſrs. Kennedy and Lee. It flowers in may[e].

19. Leaves ovate, much acuminate, unequally and ſharply ſerrate, ſmooth on both ſides. Umbels three or four-flowered[f].

Native of Canada. Introduced in 1773, by Meſſrs. Kennedy and Lee. It flowers in april and may[b].

20. The common Plum tree is of a middling ſize, growing to the height of fifteen or twenty feet, branching into a moderately-ſpreading head. Leaves on ſhort petioles, which have one or two glands towards the end; they are ſlightly ſerrate and ſmooth; when young they are convoluted or coiled, and pubeſcent underneath. Peduncles ſhort, commonly ſolitary. Calyx erect. Petals white, obovate[c]. The drupe is an oblong ſpheroid, ſwelling a little more on one ſide and there grooved, of a blue colour, with a bloom on it: pulp yellowiſh, tender. Shell bony, ovate, pointed at both ends, compreſſed, obſcurely excavated; having two longitudinal ſutures, one more gibbous, ſimple, acute, the other ſtraighter, dividing, narrow, crenulate[d].

It loves a lofty expoſure, and is favourable to paſturage. The bark dyes yellow. The cultivated garden Plums are all derived from this ſpecies.

It is a native of Aſia and Europe; perhaps ſcarcely of Britain, though it is not uncommon in our hedges, but is probably originated from the ſeeds of ſome of

[a] Gentleman's magazine for 1786. 1. 389. ſign. W. & D.

[b] Hort. kew. [c] Smith. [d] Gartner. [e] Willdenow. [f] Linn. ſuppl.

the cultivated ſpecies: which according to Pliny came from Syria into Greece, and thence into Italy.

Plums, when ſufficiently ripe, and taken in a moderate quantity, are not unwholeſome: but in an immature ſtate they are more liable to produce colicky pains, diarrhœa or cholera than any other fruit of this claſs. Conſidered medicinally, they are emollient, cooling and laxative, eſpecially the French Prunes, imported in their dried ſtate from Marſeilles; and though the laxative power is diminiſhed by drying, yet as they contain much of their acid, they have more effect in this way than the other dried fruits. They are peculiarly uſeful in coſtive habits, and are frequently ordered in decoction with Senna and other purgatives. It is the pulp of this fruit which is directed in the Electuarium e Senna, or Lenitive Electuary*.

The varieties of garden and orchard Plums are very numerous, differing in the form, taſte, colour and ſubſtance of the fruit. Parkinſon's catalogue contains ſixty ſorts, fit, as he ſays, for an orchard, to be ſtored with good fruit: all which ſorts, adds he, are to be had of my very good friend Maſter John Tradeſcante, who hath wonderfully laboured to obtain all the rareſt fruits he can hear of in any place of Chriſtendome, Turky, yea or the whole world.

1. Amber Primordian; an indifferent fair Plum, early ripe, pale yellow, taſte wateriſh.
2. Red Primordian; of a reaſonable ſize, long and round, reddiſh on the outſide, of a more dry taſte, ripe with the firſt ſorts in the beginning of auguſt.
3. Blue Primordian; ſmall, almoſt like the Damaſcene, ſubject to drop before it is ripe.
4. White Date; no very good Plum.
5. Red Date; large, long, red, pointed, late ripe, little better than the white.
6. Black Muſſell; reaſonably dry and well taſted.
7. Red Muſſell; ſomewhat flat as well as round, of a good taſte, ripe about the middle of auguſt.
8. White Muſſell; like the red, but ſomewhat ſmaller, and not ſo well taſted; colour whitiſh green.
9. Imperiall; large, long, reddiſh, wateriſh and late.
10. Gaunt; large, round, reddiſh, wateriſh, late.
11. Red Peſcod; reaſonably good.
12. White Peſcod; the ſame, but ſomewhat wateriſh.
13. Green Peſcod; reaſonably big and long-pointed; ripe in the beginning of ſeptember.
14. Orenge; yellowiſh, moiſt, and ſweetiſh.
15. Morocco; like a Damſon, well taſted and ſomewhat dry in eating.
16. Dine; late ripe, great and whitiſh, ſpeckled all over.
17. Turkie; large, long, blackiſh, ſomewhat flat like the Muſſell Plum; well-reliſhed and dry.
18. Nutmeg; no bigger than a Damſon, greeniſh yellow, ripe about Bartholomew-tide; a good Plum.
19. Perdigon; a dainty good Plum, early, blackiſh.—Hakluyt, in 1582, ſays, of later time, the plum called the *Perdigwena* was procured out of Italy, with two kinds more, by the Lord Cromwell, after his travell.
20. Verdoch; a great fine green ſhining Plum, fit to preſerve.
21. Jenua (Genoa); the ſame with the White Date, n. 4.
22. Barberry (Barbary); great, early, black, well taſted.
23. Pruneola; ſmall, white, of a fine tart taſte: brought over in ſmall round boxes, and ſold at the comfit-makers, cut in twaine, the ſtone caſt away, at a very deere rate.
24. Shepway Bulleis; dark blueiſh brown, of a ſharp taſte, larger than the common, but not ſo good.
25. White and Black Bulleis; ſmall and round, leſſer than Damſons, ſharper in taſte and later ripe.
26. Fluſhing Bulleis; thick cluſtring like grapes.—The three laſt belong to the next ſpecies or *P. inſtitia*.
27. Winter Creke; lateſt ripe of all the ſorts: plentifully about Biſhop's Hatfield.
28. White Peare Plum; early, pale yelloviſh green.
29. Late White Peare Plum; larger and longer, greeniſh white, not ripe till near the end of ſeptember: both wateriſh Plums.
30. Black Peare Plum; of a very good reliſh, more firm and dry than the others.
31. Red Peare Plum; the worſt of the three.
32. White Wheate Plum; wateriſh and fulſome.
33. Red Wheate Plum; like the other for taſte.
34. Bowle; flat and round, yet flatter on one ſide, whence the name; a very good reliſhed black Plum.
35. Friar; well-taſted, coming clean from the ſtone, black with ſome whitiſh ſpots.
36. Catalonia.
37. Don Alteza. Both very good Plums.
38. Muſcadine, Queen Mother or Cherry Plum; fair, red, of a reaſonable bigneſs, and ripe about Bartholomew-tide.
39. Chriſtian or Nutmeg Plum; good for ſix weeks after it is gathered.
40. Cherry Plum; ſee n. 38.
41. Amber; round, yellow as wax.
42. Apricocke Plum; good when in perfection, but apt to crack.
43. Eaſon; ſmall, red, well-taſted.
44. Violet; ſmall, long, blackiſh blue, ripe about Bartholomew-tide, a very good dry eating fruit.
45. Grape Plum; the ſame with n. 26.
46. Dennie or Cheſton; the ſame with n. 35.
47. Damaſke Violet; the ſame with n. 38.
48. Blacke Damaſcene; a very good dry Plum, dark blue when ripe.
49. White Damſon; not ſo well reliſhed.
50. Great Damſon or Damaſke; greater and ſweeter.
51. Blue Damſon; well known, good.
52. Coferer's; flat, like a Peare Plum, early ripe and black, of a very good reliſh.
53. Margate; the worſt of an hundred.
54. Green Oyſterly; reaſonably great, whitiſh green, moiſt and ſweet, reaſonably good.
55. Red Mirobalane; red, earlier ripe, and better than the next.
56. White Mirobalane; whitiſh yellow, and very pleaſant, eſpecially if not over-ripe: both theſe had need to be plaſhed againſt a wall, or elſe they will hardly bear ripe fruit.
57. Olive; very like a green Olive in colour and bigneſs; late ripe, but the beſt of the green Plums.
58. White Diapred Plum of Malta, ſcarce known to any in our land but John Tradeſcant: very good and ſtriped all over like Diaper.
59. Black Diapred Plum; like the Damaſcene, black with ſpots as ſmall as pin's points, of a very good reliſh.
60. Peake; long, whitiſh and very good.

Ray alſo gives a liſt of the beſt ſorts of Plums cultivated in his time.

1. Red, blue and amber Primordian.
2. Violet, red, blue and amber.
3. Matchleſs.
4. Black and green Damaſcene.
5. Morocco.
6. Barbary.
7. Myrobalane, white and red.
8. Apricock.
9. Cinnamon.
10. Great Mogul and Tawny.
11. White, red and black Pear Plum.
12. Green Oſterley.
13. Muſcle, black, red, white.
14. Catalonia.
15. White and black Prunella.
16. Bonum magnum.
17. Wheaten; ſo called becauſe it is ripe about wheat harveſt.
18. Cluſter.
19. Queen Mother.
20. Marble.
21. Imperial.
22. Peach Plum.
23. Peaſcod Plum of ſeveral colours.
24. Date-plum, white, yellow and red.
25. Nutmeg Plum.
26. Turkey.
27. Prince; laſt ripe.
28. Lammas.

* Woodville.

In Rea's catalogue there are no additions of any conſequence. Bradley has ſixty-five, from the French. Monſ. Duhamel deſcribes forty-eight varieties; and Mayer makes them ſtill more numerous.]

Mr. Miller has given thirty varieties of this fruit which are cultivated in the Engliſh gardens.

1. PRUNUS (*Jaunebâtive, Duham. n.* 1. *t.* 1.) fructu parvo præcoci. *The white Primordian.* This is a ſmall, longiſh, white Plum, of a clear yellow colour, covered over with a white flew, which eaſily wipes off. It is a pretty good bearer, and, for its coming very early, one tree may have a place in a large garden of fruit, but it is meally, and has little flavour. This ripens the middle or latter end of july.

2. PRUNUS (*Damas Noir*) fructu magno craſſo ſubacido. Tourn. *The early Damaſk, commonly called the Morocco Plum.* This is a middle ſized Plum, of a round ſhape, divided with a furrow in the middle (like Peaches.) The outſide is of a dark black colour, covered with a light violet bloom; the fleſh is yellow, and parts from the ſtone. It ripens the end of july, and is eſteemed for its goodneſs.

3. PRUNUS (*Small Damas*) fructu parvo dulci atro-cæruleo. Tourn. *The little black Damaſk Plum.* This is a ſmall black Plum covered with a light violet bloom. The juice is richly ſugared; the fleſh parts from the ſtone, and it is a good bearer. Ripe the beginning of auguſt.

4. PRUNUS (*Gros Damas, Duham. n.* 4.) fructu magno dulci atro-cæruleo. Tourn. *Gros Damas Violet de Tours, i. e. great Damaſk Violet of Tours.* This is a pretty large Plum, inclining to an oval ſhape. The outſide is of a dark blue covered with a violet bloom; the juice is richly ſugared; the fleſh is yellow, and parts from the ſtone. Ripe in auguſt.

5. PRUNUS (*Orleans*) fructu rotundo atro rubente. *The Orleans Plum.* The fruit is ſo well known to almoſt every perſon, that it is needleſs to deſcribe it; it is a very plentiful bearer, which has occaſioned its being ſo generally planted by thoſe perſons who ſupply the markets with fruit, but it is an indifferent Plum. It ripens in auguſt.

6. PRUNUS (*Fotheringham*) fructu oblongo atro-rubente. *The Fotheringham Plum.* This fruit is ſomewhat long, deeply furrowed in the middle. The fleſh is firm, and parts from the ſtone; the juice is very rich. This ripens in auguſt.

7. PRUNUS (*Perdigron*) fructu nigro, carne durâ. Tourn. *The black Perdigron Plum.* This is a middle-ſized Plum of an oval ſhape. The outſide is of a very dark colour, covered over with a violet bloom; the fleſh is firm, and full of an excellent rich juice. This is greatly eſteemed by the curious. Ripe in auguſt.

8. PRUNUS (*Perdrigon violet, Duham. n.* 21. *t.* 9.) fructu magno è violaceo rubente ſuaviſſimo ſaccharato. Tourn. *The Violet or blue Perdigron Plum.* This is a large fruit, rather round than long, of a bluiſh red colour on the outſide. The fleſh is of a yellowiſh colour, pretty firm, and cloſely adheres to the ſtone; the juice is of an exquiſite rich flavour. This ripens in auguſt.

9. PRUNUS (*Perdrigon blanc, Duham. n.* 20. *t.* 8.) fructu ovato ex albo flaveſcente. *The white Perdigron Plum.* This is a middling Plum, of an oblong figure. The outſide is yellow, covered with a white bloom; the fleſh is firm, and well taſted. It is a very good fruit to eat raw, or for ſweetmeats, having an agreeable ſweetneſs mixed with an acidity. It ripens the end of auguſt.

10. PRUNUS (*Impériale, Duh. n.* 32. *t.* 15.) fructu ovato magno rubente. Tourn. *The red Imperial Plum,* ſometimes called *the red Bonum Magnum.* This is a large oval-ſhaped fruit, of a deep red colour, covered with a fine bloom. The fleſh is very dry, and very indifferent to be eaten raw, but is excellent for making ſweetmeats; this is a great bearer. Ripe in ſeptember.

11. PRUNUS (*Impériale blanche, Duh. n.* 35.) fructu ovato magno flaveſcente. Tourn. *White imperial Bonum Magnum, white Holland, Mogul* or *Egg Plum.* This is a large oval-ſhaped fruit, of a yellowiſh colour, powdered over with a white bloom. The fleſh is firm, and adheres cloſely to the ſtone; the juice is of an acid taſte, which renders it unpleaſant to be eaten raw, but it is very good for baking or ſweetmeats. It is a great bearer, and is ripe the middle of ſeptember.

12. PRUNUS (*Cheſton*) fructu ovato cæruleo. *The Cheſton Plum.* This is a middle-ſized fruit of an oval figure. The outſide is of a dark blue, powdered over with a violet bloom; the juice is rich, and it is a great bearer. Ripe the middle of ſeptember.

13. PRUNUS (*Apricotée, Duh. n.* 28. *t.* 13.) fructu maximo rotundo flavo & dulci. Tourn. *Prune d'Abricot, i. e. the Apricot Plum.* This is a large round fruit of a yellow colour on the outſide, powdered over with a white bloom. The fleſh is firm and dry, of a ſweet taſte, and comes clean from the ſtone. This ripens the end of ſeptember.

14. PRUNUS (*Maître Claud*) fructu ſubrotundo, ex rubro & flavo mixto. *The Maître Claud.* Although this name is applied to this fruit, yet it is not what the French ſo call. This is a middle-ſized fruit, rather round than long, of a fine mixed colour between red and yellow. The fleſh is firm, parts from the ſtone, and has a delicate flavour. Ripe the end of ſeptember.

15. PRUNUS (*Diaprée*) fructu rubente dulciſſimo. Tourn. *Rochecorbon,* or *Diaprée rouge, Duh. n.* 37. *t.* 20. *f.* 12. This is a large round fruit, of a reddiſh colour, powdered over with a violet bloom; the fleſh adheres cloſely to the ſtone, and is of a very high flavour. Ripe the end of auguſt.

16. PRUNUS fructu rotundo flaveſcente. *La petite Reine Claude, Duh. n.* 26. This is a ſmall round fruit, of a whitiſh yellowiſh colour, powdered over with a pearl-coloured bloom; the fleſh is firm and thick, quits the ſtone, and its juice is richly ſugared. Ripe the end of auguſt.

17. PRUNUS fructu rotundo nigro purpureo majori dulci. Tourn. *Myrobalan Plum, Duh. n.* 46. *t.* 20. *f.* 15. This is a middleſized fruit, of a round ſhape; the outſide is a dark purple, powdered over with a violet bloom; the juice is very ſweet. It is ripe the end of auguſt.

18. PRUNUS fructu rotundo è viridi flaveſcente, carne duro ſuaviſſimo. *La groſſe Reine Claude,* or *Dauphine, Duh.* 25. *t.* 11. At Tours it is called Abricot vert; at Rouen, verte bonne; and in other places, Damas vert, or Tromp-valet. This is one of the beſt Plums in England; it is of a middle ſize, round, and of a yellowiſh green colour on the outſide; the fleſh is firm, of a deep green colour, and parts from the ſtone; the juice has an exceeding rich flavour, and it is a great bearer. Ripe the middle of ſeptember. This Plum is confounded by moſt people in England, by the name of Green Gage; but this is the ſort which ſhould be choſen, although there are three or four different ſorts of Plums generally ſold for it, one of which is ſmall, round, and dry; this quits the ſtone, and is later ripe, ſo not worth preſerving.

19. PRUNUS fructu amygdalino. Tourn. *Regnon de Coq, i. e. Cock's Teſticles.* This is an oblong fruit, deeply furrowed in the middle, ſo as to reſemble the teſticles; it is of a whitiſh colour on the outſide, ſtreaked with red; the fleſh of it adheres firmly to the ſtone, and it is late ripe.

20. PRUNUS fructu rotundo flavo dulciſſimo. *Drap d'Or, i. e. the Cloth of Gold Plum, Duham. n.* 30. This is a middle-ſized fruit, of a bright yellow colour, ſpotted or ſtreaked with red on the outſide; the fleſh is yellow, and full of an excellent juice. It is a plentiful bearer, and ripens about the middle of ſeptember.

21. PRUNUS fructu cerei coloris. Tourn. *Sainte Catharine, Duham. n.* 43. *t.* 19. This is a large oval-ſhaped fruit, ſomewhat flat; the outſide is of an amber colour, powdered over with a whitiſh bloom, but the fleſh is of a bright yellow colour, is dry and firm, adheres cloſely to the ſtone, and has a very agreeable ſweet taſte. This ripens at the end of ſeptember, and is very ſubject to dry upon the tree, when the

autumn

autumn proves warm and dry. This makes fine ſweetmeats, and is a plentiful bearer.

22. PRUNUS fructu ovato rubente dulci. *The Royal Plum. Duham. n.* 24. *t.* 10. This is a large fruit of an oval ſhape, drawing to a point next the ſtalk; the outſide is of a light red colour, powdered over with a whitiſh bloom; the fleſh adheres to the ſtone, and has a fine ſugary juice. This ripens the middle of ſeptember.

23. PRUNUS fructu parvo ex viridi flaveſcente. Tourn. *La Mirabelle. Duham. n.* 29. *t.* 14. This is a ſmall round fruit, of a greeniſh yellow on the outſide; the fleſh parts from the ſtone, is of a bright yellow colour, and has a fine ſugary juice. This is a great bearer, ripens the end of auguſt, and is excellent for ſweetmeats.

24. PRUNUS Brigonienſis, fructu ſuaviſſimo. Tourn. *Prune de Brignole, i. e. the Brignole Plum.* This is a large oval-ſhaped fruit, of a yelloviſh colour, mixed with red on the outſide; the fleſh is of a bright yellow colour, is dry, and of an excellent rich flavour. This ripens the middle of ſeptember, and is eſteemed the beſt Plum for ſweetmeats yet known.

25. PRUNUS fructu magno è violaceo rubente ſerotino. Tourn. *Imperatrice, i. e. the Empreſs. Duham. n.* 39. *t.* 18. This is a large round fruit, of a violet red colour, very much powdered with a whitiſh bloom; the fleſh is yellow, cleaves to the ſtone, and is of an agreeable flavour. This ripens about the beginning of october.

26. PRUNUS fructu ovato maximo flavo. Tourn. *Prune de Monſieur, i. e. Monſieur's Plum. Duham. n.* 15. *t.* 7. This is ſometimes called the Wentworth Plum. It is a large oval-ſhaped fruit, of a yellow colour both within and without, very much reſembling the Bonum Magnum, but the fleſh of this parts from the ſtone, which the other doth not. This ripens towards the latter end of ſeptember, and is very good to preſerve, but the juice is too ſharp to be eaten raw. It is a great bearer.

27. PRUNUS fructu majori rotundo rubro. Tourn. *Prune Cerizette, i. e. the Cherry Plum.* This fruit is commonly about the ſize of the Ox-heart Cherry, is round, and of a red colour; the ſtalk is long like that of a Cherry, which this fruit ſo much reſembles, as not to be diſtinguiſhed therefrom at ſome diſtance. The bloſſoms of this tree come out very early in the ſpring, and being tender, are very often deſtroyed by cold, but it affords a very agreeable proſpect in the ſpring; for theſe trees are generally covered with flowers, which open about the ſame time as the Almonds; ſo that when they are intermixed therewith, they make a beautiful appearance before many other ſorts put out; but by this bloſſoming ſo early, there are few years that they have much fruit.

28. PRUNUS fructu albo oblongiuſculo acido. Tourn. *The white Pear Plum.* This is a good fruit for preſerving, but is very unpleaſant if eaten raw; it is very late ripe, and ſeldom planted in gardens, unleſs for ſtocks to bud ſome tender ſorts of Peaches upon, for which purpoſe it is eſteemed the beſt amongſt all the ſorts of Plums.

29. PRUNUM Mytellinum. Park. *The Muſcle Plum.* This is an oblong flat Plum, of a dark red colour; the ſtone is large, and the fleſh but very thin and not well taſted, ſo that its chief uſe is for ſtocks, as the former.

30. PRUNUS fructu parvo violaceo. *The St. Julian Plum.* This is a ſmall fruit, of a dark violet colour, powdered over with a mealy bloom; the fleſh adheres cloſely to the ſtone, and in a fine autumn will dry upon the tree. The chief uſe of this Plum is for ſtocks, to bud the more generous kinds of Plums and Peaches upon; as alſo for the Bruxelles Apricot, which will not thrive ſo well upon any other ſtock.

[Mr. Miller makes no mention of—

31. The Green Gage, unleſs he intends it by n. 18. It is the fineſt eating Plum we have, eſpecially when it is tinged with purple, is ripe in auguſt and ſeptember, and ripens very well on ſtandards or eſpaliers.

32. Blue Gage; ripe in ſeptember. A middle ſized, roundiſh, blueiſh Plum, of a rich flavour.

33. Wentworth; large, oval, yelloviſh, acid and parting from the ſtone, uſed chiefly for tarts and ſweetmeats, like n. 10 and 11.

34. Damaſcene, vulgarly Damſon; ſmall, roundiſh, dark blue, a great bearer; in orchards for the kitchen: ripe in ſeptember.

Ornamental varieties are the Double-bloſſomed; the Gold-ſtriped; the Silver-ſtriped; and the ſtoneleſs Plum.

21. The Bullace tree grows twelve or fifteen feet high or more. The branches are generally thorny. Leaves on ſhort petioles, ovate attenuated at the baſe, ſerrate, villoſe underneath. Calyx almoſt upright. Petals white, obovate. Drupe roundiſh[f].

Linnæus remarks, that the ſtipules are narrow, fringed, ſharp, cloven at the baſe; or down to the baſe, according to Withering; who alſo obſerves, that the outer ſkin of the calyx may be pulled off, adhering to the peduncle, and appearing like an outer cup.

The fruit is acid, but ſo tempered by ſweetneſs and roughneſs as not to be unpleaſant, eſpecially after it is mellowed by froſt. A conſerve is prepared by mixing the pulp with thrice its weight of ſugar. The bark of the roots and branches is conſiderably ſtyptic. An infuſion of the flowers, ſweetened with ſugar, is a mild purgative, not improper for children[g].

Native of Germany, Switzerland, France and England, in hedges; flowering in april.

It varies with black, and white, or rather wax-coloured fruit; and alſo, as Mr. Dale ſays, with a red, bitter, unpleaſant fruit, in the hedges of Eſſex and Suffolk.

22. Root creeping. Stem ſhrubby, crooked, ſix or eight feet high, covered with a dark-coloured bark. Branches many, irregularly divaricating, ending in a thorn. Leaves on ſhort petioles, obovate-lanceolate, minutely ſerrate; the ſerratures terminated by an excretory duct, the terminating one blunter and ſhorter. Stipules linear, ſerrate-toothed, diſcoloured at the points. Flowers large, white, ſolitary on ſhort peduncles, coming out before the leaf in march or april. Calyx ſpreading. Filaments from twenty to thirty, with orange-coloured anthers. Dr. Stokes remarks, that there are ſometimes two ſtyles. Drupe roundiſh, black with a blue exudation or bloom[h].—Native of Europe in hedges and coppices.

The Black-thorn is not ſo well adapted to hedges as the White-thorn, becauſe it ſpreads its roots wide, and encroaches upon the paſturage; but it is excellent for dead fences, and to lay in covered drains. The wood is hard and tough, and is formed into teeth for rakes, and into walking ſticks. From ſome effects, ſays Dr. Withering, which I have repeatedly obſerved to follow a wound from the thorns, I have reaſon to believe there is ſomething poiſonous in them, particularly in autumn. The tender leaves dried are ſometimes uſed as a ſubſtitute for tea, and is the beſt ſubſtitute that has yet been tried. The bark powdered, in doſes of two drams, will cure ſome agues. Letters marked upon linnen or woollen, with the juice of the fruit, will not waſh out. Bruiſed and put into wine, it communicates a beautiful red colour, and a pleaſant ſubacid roughneſs[i]. The juice is ſaid to enter largely into the manufacture of Red Port Wine; and I have known the leaves gathered in conſiderable quantities to mix with the Chineſe Tea.

The Sloe is ſo harſhly ſharp and auſtere as not to be eatable till it is mellowed by froſt: its juice is extremely viſcid, ſo that the fruit requires the addition of a little water, in order to admit of expreſſion. The juice obtained from the unripe fruit, and inſpiſſated to dryneſs by a gentle heat, is the German Acacia, and has been uſually ſold in the ſhops for the Egyptian Acacia, from which it differs in being harder, heavier, darker-coloured, of a ſharper taſte, and more

[f] Smith. [g] Withering.
[h] Woodville, Smith, Linn. [i] Withering.

eſpecially

eſpecially in giving out its aſtringency to rectified ſpirit.

Sloes have been employed for their ſtyptic powers from the time of Dioſcorides. They have been recommended in diarrhœas and hæmorrhages, and as gargles in ſwellings of the tonſils and uvula. Dr. Cullen conſiders them as the moſt powerful of the acerb fruits, and as agreeable and uſeful aſtringents; but he thinks the conſerve, as directed by the College, contains a larger proportion of ſugar than is neceſſary.

The flowers, with their calyxes, are moderately purgative, the doſe is an ounce infuſed in water, or rather whey[x].

23. Branches and branchlets round, dotted. Leaves alternate, petioled, acuminate, veined, rugged on both ſides, pale underneath, ſpreading, two inches long. Petiole very ſhort, grooved. Flowers on the extreme branchlets. Drupe the ſize of Pepper, globular or ovate with a permanent ſtyle, blue, ſmooth. Nut or ſtone three-ſided, hard, ovate, ſharpiſh. Kernel whitiſh. Fruit eatable. The upper ſurface of the leaf is ſo hard that it is uſed in poliſhing in Japan, where it is a native.

24. Stem ſhrubby, wholly ſmooth. Branches and branchlets alternate, round, aſh-coloured, wrinkled, erect. Leaves alternate, petioled, veined, ſpreading, an inch long. Stipules in pairs, leafy above, briſtle-ſhaped, the length of the petiole. Peduncle below the branchlets, one-flowered, ſhort. Drupe the ſize of a pea.—Native of Japan.

25. Stem ſhrubby, ſmooth in all parts. Branches round, ſtriated, aſh-coloured, with the branchlets gradually filiform. Leaves ſcattered, petioled, oblong, ſpreading, netted-veined underneath. Petioles ſeveral times ſhorter than the leaves. Flowers ſcattered, ſolitary. Peduncles pendulous, the length of the leaves. Calyx ſubcampanulate. Corolla fleſh-coloured.

It differs from *P. pumila* in having the leaves acute very finely ſerrate and of the ſame colour on both ſides; not obtuſe almoſt entire and glaucous:—from *P. inciſa* by its ſmooth ſerrate leaves with the ſerratures glandular.—Native of Japan.

26. Stem arboreous, ſlim, weak, a fathom in height. Branches and branchlets alternate, flexuoſe, ſmooth, aſh-coloured, ſpreading. Leaves from the ends of the branches ſeveral, acute, ſhort in flowering time, but afterwards becoming longer. Petioles ſhorter by half than the leaves. Flowers from the tops of the branchlets, fleſh-coloured. Peduncles capillary, ſmooth, double the length of the leaves. Calyx cylindrical, widening at top, ſmooth, ferrûginous, ſhorter by half than the corolla. It differs from *P. inſtitia* in its ſolitary peduncles, unarmed branches, and gaſh-ſerrate leaves:—from *P. ſpinoſa* by its ovate hairy gaſh-ſerrate leaves and unarmed branches.—Native of Japan.

27. Stem arboreous: branches ſmooth erect: branchlets alternate ſpreading tomentoſe. Leaves alternate, acute, ſerrate, veined, villoſe above, ſpreading, about an inch in length. Petioles tomentoſe, half a line long. Flowers peduncled. Drupe the ſize of a pea.—Native of Japan[t].

28. Stems fruteſcent, procumbent, very much branched. Leaves acuminate to both ends, on ſhort petioles. Stipules in pairs, narrow-lanceolate or briſtle-ſhaped. Flowers commonly in pairs, axillary, ſubſeſſile, pale purple roſe-coloured or white. Drupe ſmall, ovate, red with very little pulp: nut or ſtone ovate with the ſutures ſcarcely prominent[u]: which diſtinguiſhes it from the Almond, to whoſe habit it approaches.

Native of the mountains of Crete; on mount Libanus at the height of one thouſand fathoms; and if the Amygalus incana of Pallas be the ſame with this, it is found alſo on Caucaſus, about Kſauriſi and Teflis. Deſfontaines obſerved it on mount Atlas.

29. According to Willdenow, this is Padus virginiana of Miller's Dictionary, and Prunus virginiana of Du Roi: he ſays it is eaſily diſtinguiſhed, although the leaves vary much in form, by the midrib being bearded underneath towards the baſe.

Native of North America. See Miller's deſcription, and the ſynonyms of Gronovius, Cateſby, &c. under n. 3.

30. This reſembles Prunus ſibirica, but differs in having the leaves doubly ſerrate, and the petioles glandular. It is commonly known in the gardens under the French name of *Abricot noir*. Suppoſed to be a native of the Levant.

31. This is probably a mule preſerving its difference in gardens.

32. This is a ſhrub without thorns, three or four feet high. Leaves attenuated at the baſe, ſharply ſerrate, the laſt tooth having a gland on each ſide. Flowers four or five together cluſtered in an umbel, and of the ſame ſize with thoſe of the Black-thorn. Fruit as large as a great pea, black, with very little pulp.—Native of North America[v].

33. This has been generally conſidered as a variety of Prunus domeſtica or the common Plum. The branches are very ſmooth but ſomewhat thorny, the leaves are convoluted; the peduncles very ſlender and ſmooth; the calyx reflex; the drupe ſubglobular, dark purple or red and ſweet[w].—Native of North America.]

PROPAGATION AND CULTURE.

1, 2, 29. The two firſt ſorts and the twenty-ninth are eaſily propagated either by ſeeds or layers. Sow the ſeeds in the autumn upon a bed or border of good ground, in the ſame way as Cherry-ſtones deſigned for ſtocks. Treat the plants alſo in the ſame manner; planting them out in a nurſery, where they may ſtand two years to get ſtrength; and then tranſplant them to the places where they are to remain. They are uſually intermixed with other flowering-trees and ſhrubs in ornamental plantations.

For layers, the young ſhoots ſhould be laid down in the autumn: theſe will have good roots in twelve months, when they may be ſeparated from the old plants, and tranſplanted into a nurſery for a year or two, to get ſtrength, and may then be removed to the places where they are to grow.

5. Plant this in a warm ſituation, and ſhelter it from ſevere froſt, whilſt young: when it has acquired ſtrength, it will thrive very well in the open ground in ſheltered ſituations. It may be propagated in the ſame manner as the Portugal Laurel from the berries; and if the branches are laid down, they will take root.

8. The Portugal Laurel may be propagated in the ſame way as the common Laurel, by cuttings, layers, or ſeeds. If the cuttings are planted at the ſame ſeaſon, and in the ſame way as will be directed for the common Laurel, they will take root very freely; or if the young branches are laid in the autumn, they will take root in one year, and may then be removed into a nurſery, where they may grow a year or two to get ſtrength, and then be tranſplanted where they are to remain.

But although both theſe methods are very expeditious for the propagating thoſe plants, yet I would recommend the raiſing them from the berries, eſpecially where they are deſigned for tall ſtandards; for the plants which are propagated by cuttings and layers, put out more lateral branches and become buſhy, but are not ſo well inclined to grow upright, as thoſe which come from ſeeds: and as there are now many trees in the Engliſh gardens which produce plenty of berries every year, if they are guarded from birds till they are ripe, there may be a ſupply of them ſufficient to raiſe plants enough without propagating them any other way. Theſe berries muſt be ſown in the autumn, and treated in the ſame way as the common Laurel.

This tree delights in a gentle loamy ſoil, which is not too wet nor over dry, though it will grow upon almoſt any ſoil: but the plants do not make ſo great progreſs, nor appear ſo beautiful, when planted in a

[x] Woodville. [t] Thunberg. [u] Billard. & Deſfont. [v] Willdenow. [w] Ehrhart.

very

very dry ſoil, or in ground that is over wet. The time of tranſplanting them is the ſame as for the common Laurel.

This is much hardier than that; for in the ſevere froſt of the year 1740, when great numbers of Laurels were entirely killed, and moſt of them loſt their verdure, this remained unhurt: and as it grows to a conſiderable ſize, and the dark-green leaves make a fine mixture with the elegant ſpikes of white flowers, it is one of the moſt valuable evergreens we have.

[In ſeveral winters ſince 1740, the Portugal Laurels have ſuffered ſeverely. In 1784, during the month of december, all thoſe which ſtood in ſunny aſpects not only loſt their foliage, but were cut to the ground, though they afterwards revived. Many Portugal Laurels alſo round London were cut to the ground by the froſt in january 1776.]

9. The Laurel may be eaſily propagated by ſeeds or by planting of the cuttings; the beſt time for doing the latter is in ſeptember, as ſoon as the autumnal rains fall to moiſten the ground; the cuttings muſt be the ſame year's ſhoots, and if they have a ſmall part of the former year's wood to their bottom, they will more certainly ſucceed, and form better roots. Theſe ſhould be planted in a ſoft loamy ſoil about ſix inches deep, preſſing the earth cloſe to them. If theſe are properly planted, and the ground is good, there will few of the cuttings fail; and if they are kept clean from weeds the following ſummer, they will have made good ſhoots by the following autumn, when they may be tranſplanted into a nurſery, where they may grow two years to get ſtrength, and then ſhould be removed to the places where they are to remain. Theſe plants were formerly kept in pots and tubs, and preſerved in green-houſes in winter; but afterward they were planted againſt warm walls, to preſerve them, being frequently injured by ſevere froſt. After this the plants were trained into pyramids and globes, and conſtantly kept ſheered; by which the broad leaves were generally cut in the middle, which rendered the plants very unſightly. Of late years they have been more properly diſpoſed in gardens, by planting them to border woods, and the ſides of wilderneſs quarters; for which purpoſe we have but few plants ſo well adapted, for it will grow under the drip of trees, in ſhade or ſun; and the branches will ſpread to the ground, ſo as to form a thicket; and the leaves being large, and having a fine gloſſy green colour, they ſet off the woods and other plantations in winter, when the other trees have caſt their leaves; and in ſummer they make a good contraſt with the green of the other trees. Theſe trees are ſometimes injured in very ſevere winters, eſpecially where they ſtand ſingle and are much expoſed; but where they grow in thickets, and are ſcreened by other trees, they are ſeldom much hurt; for in thoſe places it is only the young tender ſhoots which are injured, and there will be new ſhoots produced immediately below theſe to ſupply their place, ſo that in one year the damage will be repaired. But whenever ſuch ſevere winters happen, theſe trees ſhould not be cut or pruned till after the following midſummer; by which time it will appear what branches are dead, which may then be cut away, to the places where the new ſhoots are produced; for by haſtily cutting theſe trees in the ſpring, the drying winds have free ingreſs to the branches, whereby the ſhoots ſuffer as much, if not more, than they had done by the froſt.

Theſe trees are alſo very ornamental, when they are mixed with other evergreen trees, in forming of thickets, or to ſhut out the appearance of diſagreeable objects; for the leaves being very large, make a very good blind, and are equally uſeful for ſcreening from winds; ſo that when they are planted between flowering-ſhrubs, they may be trained ſo as to fill up the vacancies in the middle of ſuch plantations; and will anſwer the purpoſe of ſcreening in the winter, and ſhutting out the view through the ſhrubs in all ſeaſons: there are alſo many other purpoſes to which this tree may be applied, ſo as to render it very ornamental.

In warmer countries this tree will grow to a great ſize, ſo that in ſome parts of Italy there are large woods of them; but we cannot hope to have them grow to ſo large ſtems in England; for ſhould theſe trees be pruned up, in order to form them into ſtems, the froſt would then become much more hurtful to them than in the manner they uſually grow, with their branches to the ground: however, if the trees are planted pretty cloſe together in large thickets, and permitted to grow rude, they will defend each other from the froſt, and they will grow to a conſiderable height: an inſtance of which is now in that noble plantation of evergreen trees, made by his Grace the Duke of Bedford at Wooburn-abbey, where there is a conſiderable hill covered entirely with Laurels; and in the other parts of the ſame plantation, there are great numbers of theſe intermixed with the other evergreen trees, where they are already grown to a conſiderable ſize, and make a noble appearance.

There are ſome perſons who propagate theſe trees from their berries, which is certainly the beſt way to obtain good plants; for thoſe which come from ſeeds have a diſpoſition to an upright growth, whereas almoſt all thoſe which are raiſed from cuttings or layers, incline more to an horizontal growth, and produce a greater number of lateral branches. When any perſon is deſirous to propagate this tree by ſeeds, the berries muſt be guarded from the birds, otherwiſe they will devour them before they are perfectly ripe, which is ſeldom earlier than the latter end of ſeptember, or the beginning of october, for they ſhould hang until the outer pulp is quite black. When theſe berries are gathered, they ſhould be ſown ſoon after; for when they are kept out of the ground till ſpring, they frequently miſcarry; and there will be no hazard in ſowing them in the autumn, provided they are put in a dry ſoil; and if the winter ſhould prove ſevere, the bed in which they are ſown ſhould be covered with rotten tan, ſtraw, Peas-haulm, or any light covering, to prevent the froſt from penetrating of the ground. The beſt way will be to ſow the berries in rows at about ſix inches diſtance, and one inch aſunder in the rows; if drills are made about three inches deep, and the berries ſcattered in them, and the earth drawn over them, it will be a very good method. The following ſpring the plants will appear, when they ſhould be kept clean from weeds; and if the ſeaſon ſhould prove dry, if they are duly watered, the plants will make ſo good a progreſs as to be fit for tranſplanting the following autumn, when they ſhould be carefully taken up, and planted in a nurſery, placing them in rows at three feet aſunder, and the plants one foot diſtance in the rows. In this nurſery they may remain two years, by which time they will be fit to tranſplant where they are deſigned to remain.

The beſt ſeaſon for tranſplanting theſe plants is in the autumn, as ſoon as the rain has prepared the ground for planting; for although they often grow when removed in the ſpring, yet thoſe do not take ſo well, nor make ſo good progreſs as thoſe which are removed in the autumn, eſpecially if the plants are taken from a light ſoil, which generally falls away from their roots; but if they are taken up with balls of earth to their roots, and removed but a ſmall diſtance, there will be no danger of tranſplanting them in the ſpring, provided it is done before they begin to ſhoot; for as the plants will ſhoot very early in the ſpring, ſo if they are removed after they have ſhot, the ſhoots will decay, and many times the plants entirely fail.

There are ſome perſons who have grafted the Laurel upon Cherry ſtocks, with deſign to enlarge the trees, but although they will take very well upon each other, yet they ſeldom make much progreſs when either the Laurel is grafted on the Cherry, or the Cherry upon the Laurel; ſo that it is only a thing of curioſity, attended with no real uſe: and I would recommend to perſons who have this curioſity, to graft the Laurel upon the Corniſh Cherry, rather than any other ſort of ſtock, becauſe the graft will unite better with this; and as it is a regular tree and grows large, ſo it will better anſwer the purpoſe of producing large trees.

[In propagating the Laurel from cuttings, the under leaves ſhould be ſtripped off. The cuttings may be ſet thick. The weather ſhould be rainy or at leaſt cloudy when this work is done; and the beds ſhould be under a north wall, or elſe well ſhaded. If the weather will permit the cuttings to be planted in auguſt, they will the more certainly take root before winter; but they ſhould remain undiſturbed till the ſpring twelvemonth following, when they ſhould be carefully taken out, and planted in the nurſery[p].

To raiſe the Laurel from ſeeds, in the beginning of winter, ſoon after they are ripe, ſow them in a ſhady border of freſh looſe mould, in beds three feet and a half broad, with alleys of eighteen inches, covering them an inch and half or two inches deep. About the middle of april, if the weather be dry and not froſty, water them frequently in the morning, and continue this during the ſummer months on evenings. The ſucceeding ſpring remove them to the nurſery, in rows two feet aſunder, and nine or ten inches in the row. In two years, if the ground be good, and they have been taken good care of, they will be fit to remove finally[q].

The ſeed-beds may be hooped over, that they may be covered occaſionally with mats when the froſt is ſevere.

When a large plantation of Laurels is intended, the work of tranſplanting may be done at any time during the winter, when the weather will permit; but october is the beſt ſeaſon. The ground muſt be well worked and cleaned, and the trees planted in holes a yard aſunder. When they begin to touch, ſtill let them remain unthinned two or three years longer, to draw one another up. Thin them ſparingly at firſt, only taking out a weakly plant here and there, to make room for the vigorous ſhooting of the others; leſt the cold, entering the plantation too much at once, ſhould retard its growth, if not wholly deſtroy it.

12. Perfumed Cherry is often propagated by grafting upon any ſort of Cherry ſtock.]

13. Apricots. Moſt people train theſe trees up to ſtems of ſix or ſeven feet high, or bud them upon ſtocks of that height; but this is a practice I would not recommend to the public, becauſe the higher the heads of theſe trees are, the more they are expoſed to the cutting winds in the ſpring, which too frequently deſtroy the bloſſoms: and the fruit is alſo more liable to be blown down in ſummer, eſpecially if there ſhould happen to be much wind at the time when the fruit is ripe; which by falling from a great height, will be bruiſed and ſpoiled; therefore I prefer half ſtandards, of about two and a half, or three feet in the ſtem, to thoſe which are much taller; or to plant them as dwarfs againſt an eſpalier, where, if they are ſkilfully managed, they will produce a large quantity of good fruit; and the trees in eſpalier may be more conveniently covered in the ſpring, when the ſeaſon proves bad, whereby there will be a greater certainty of fruit every year.

Theſe fruits are all propagated by budding them on Plum-ſtocks, and will readily take upon almoſt any ſort of Plum, provided the ſtock be free and thriving (except the Bruſſels kind, which is uſually budded on a ſort of ſtock, commonly called the St. Julian, which better ſuits this tree, as being generally planted for ſtandards, than any other ſort of Plum will.) The manner of raiſing the ſtocks, and budding theſe trees, is treated of under their particular articles, to which I refer the reader, and ſhall proceed to their planting and management.

Theſe trees are all except the two laſt ſorts (planted againſt walls, and ſhould have an eaſt or weſt aſpect; for if they are planted full ſouth, the great heat cauſes them to be mealy before they are eatable.

The borders near theſe walls ſhould be ſix or eight feet wide, at leaſt, and if it were more, the better; but I would never adviſe the making of them ſo deep as is the general cuſtom, for if the earth be two feet deep, or two and a half at moſt, it is enough.

[p] Hunter on Evelyn. [q] Boutcher.

If the ground is a wet cold loam or clay, the borders ſhould be raiſed as much above the level of the ſurface as it will admit, laying ſome ſtones or rubbiſh in the bottom, to prevent the roots from running downwards; but if you plant upon a chalk or gravel, it will be better to raiſe the borders to a proper thickneſs, with good loamy earth, than to ſink the borders by removing the chalk or gravel; for although theſe are removed the whole breadth of the border, which we may allow to be eight feet, and this trench filled with good earth, yet the roots of the trees will in a few years extend this length, and then meeting with the chalk or gravel, they will receive a check whereby their leaves will fall off early in the ſeaſon, and the fruit will be ſmall, dry, and ill-flavoured, and the ſhoots of the trees will be weak. But where the borders are raiſed above either to their full height, the roots will not ſtrike down into the gravel or chalk, but rather extend themſelves near the ſurface, where they will meet with better ſoil: and as the trees are of long duration, and old trees are not only more fruitful than young, but the fruit is alſo better flavoured, the providing for their continuance is deſirable.

The ſoil I would in general adviſe to be uſed for theſe, and all other ſorts of fruit-trees, is freſh untried earth, from a paſture ground, taken about ten inches deep, with the turf and laid to rot and mellow at leaſt twelve months before it is uſed, mixing a little rotten dung with it; this muſt be often turned, to ſweeten and imbibe the nitrous particles of the air.

When the former ſoil of the border is taken away, this freſh earth ſhould be carried in the place; and if the borders are filled with it two months before the trees are planted, the ground will be better ſettled, and not ſo liable to ſink after the trees are planted: in filling the borders, the ground ſhould be raiſed four or five inches above the level they are deſigned, to allow for the ſettling.

The borders being thus prepared, make choice of ſuch trees as are but of one year's growth from budding; and if the ſoil is dry, or of a middling temper, october is the beſt ſeaſon for planting, eſpecially having at that time a greater choice of trees from the nurſeries, before they have been picked and drawn over by other people. The manner of preparing theſe trees for planting being the ſame in common with other fruit trees, I ſhall refer the reader to the article of Peaches, where he will find it largely treated of. At the time of planting no part of the head of the trees ſhould be cut off, unleſs there are any ſtrong foreright ſhoots which will not come to the wall, which may be taken quite away.

The trees being thus prepared, you muſt mark out the diſtances they are to ſtand, which in a good ſtrong ſoil, or againſt a low wall, ſhould be twenty feet or more; but in a moderate one, eighteen feet is a good reaſonable diſtance; then make a hole where each tree is to ſtand, and place its ſtem about four inches from the wall, inclining the head thereto; and after having fixed the tree in the ground, nail the branches to the wall, to prevent their ſhaking, and cover the ſurface of the ground round the root with rotten dung, to keep out the froſt: in this ſtate let it remain till the end of february or the beginning of march, when if the weather is good, you muſt unnail the branches of your trees, ſo as not to diſturb their roots; and, being provided with a ſharp knife, put your foot cloſe to the ſtem of the tree; and having placed your left-hand to the bottom of the tree, to prevent its being diſturbed, with your right-hand cut off the head of the tree, if it has but one ſtem; or where it may have two or more ſhoots, each of them muſt be ſhortened, to about four or five eyes above the bud, ſo that the ſloping ſide may be toward the wall.

In the ſpring, if the weather proves dry, it will be neceſſary to give the trees a gentle refreſhing with water; in the doing of which, if they be watered with a roſe to the watering-pot all over their heads, it will greatly help them; and alſo lay ſome turf, in the manner directed for Apples, or ſome other mulch, round their roots, to prevent their drying during the ſummer

ſummer ſeaſon; and in the ſpring, as new branches are produced, obſerve to nail them to the wall in a horizontal poſition; and ſuch ſhoots as are produced fore-right, muſt be entirely diſplaced. This muſt be repeated as often as is neceſſary, to prevent their hanging from the wall, but by no means ſtop any of the ſhoots in ſummer.

At michaelmas, when the trees have done growing, their branches ſhould be unnailed, and ſhorten them in proportion to their ſtrength; a vigorous branch may be left eight or nine inches long, but a weak one ſhould not be left above five or ſix. I ſuppoſe many perſons will wonder at this direction, eſpecially having allowed ſuch a diſtance between the trees, as believing, by this management, the wall will never be filled; but my reaſon for it is, that I would have no part of the wall left unfurniſhed with bearing wood; which muſt be the caſe, if the branches are left to a greater length at firſt; for it ſeldom happens, that more buds than two or three upon each branch ſhoot; and theſe are, for the moſt part, ſuch as are at or near the extreme part of the laſt year's wood; ſo that all the lower parts of the ſhoots become naked, nor will they ever after produce ſhoots; and this is the reaſon we ſee ſo many trees which have their bearing wood ſituated only in the extreme part of the tree.

When you have ſhortened the ſhoots, be ſure to nail them as horizontally as poſſible, for upon this it is that the future good of the tree chiefly depends.

The ſecond ſummer obſerve, as in the firſt, to diſplace all fore-right ſhoots as they are produced, nailing in the other cloſe to the wall horizontally, ſo that the middle of the tree may be kept open; and never ſhorten any of the ſhoots in ſummer, unleſs to furniſh branches to fill vacant places on the wall; and never do this later than the end of april, for reaſons given in the article of Peaches. At michaelmas ſhorten theſe ſhoots, as was directed for the firſt year; the ſtrong ones may be left nine or ten inches, and the weak ones ſix or ſeven at moſt.

The following year's management will be nearly the ſame with this, but only obſerve, that Apricots produce their bloſſom buds, not only upon the laſt year's wood, but alſo upon the curſons, or ſpurs, which are produced from the two year's wood; a great care ſhould therefore be had in the ſummer management, not to hurt or diſplace theſe: obſerve alſo to ſhorten the branches at the winter pruning, ſo as to furniſh freſh wood in every part of the tree; and be ſure to cut out entirely all luxuriant branches, or diſplace them as ſoon as they are produced; which, if left to grow, would exhauſt the nouriſhment from the bearing branches, which in my opinion, cannot be too ſtrong, provided they are kindly; for the more vigorous the tree is, the more likely it is to reſiſt the injuries of the weather; though we often ſee trees brought to ſo weak a condition, as to be able only faintly to blow their bloſſoms, and then moſt of the bearing branches have died; which has given occaſion to the owner to imagine it was the effect of a blight, when, in reality, it was only for want of right management. And, I am fully perſuaded, half the blights we hear complained of, proceed from nothing elſe but this.

Theſe few rules, well executed, together with a little obſervation and care, will be ſufficient; to pretend to preſcribe particular directions for all the different accidents, or manner of treating fruits, would be impoſſible; but I believe the reader will find what has been ſaid, if duly attended to, will anſwer his deſign; for, without diligent obſervation, there can be no ſuch thing as a ſkilful manager, let him have ever ſo many or good inſtructions laid down to him.

The Bruſſels and Breda Apricots, being, for the moſt part, planted for ſtandards, will require very little pruning or management; only obſerve to take out all dead wood, or ſuch branches as croſs each other; this muſt be done early in autumn, or in the ſpring, after the cold weather is paſt, that the part may not canker where the inciſion is made.

15. The dwarf Canadian Cherry tree is eaſily propagated by laying down the branches early in the ſpring. They will take root by the following autumn, when they may be taken off, and either planted in a nurſery to get ſtrength, or to the places where they are deſigned to remain. It may alſo be propagated by ſowing the ſtones in the ſame manner as the common Cherry.

16. All the ſorts of Cherries which are uſually cultivated in fruit-gardens, are propagated by budding or grafting the ſeveral kinds into ſtocks of the black or wild red Cherries, which are ſtrong ſhooters, and of a longer duration than any of the garden kinds. The ſtones of the wild Cherries are ſown in a bed of light ſandy earth in autumn; or are preſerved in ſand till ſpring, and then ſowed. The young ſtocks ſhould remain in the nurſery beds till the ſecond autumn after ſowing; at which time prepare an open ſpot of good freſh earth, well worked. In october plant out the young ſtocks at three feet diſtance row from row, and about a foot aſunder in the rows; being careful in taking them up from their ſeed-beds, to looſen their roots well with a ſpade, to prevent their breaking. Prune their roots; and if they are inclinable to root downwards, ſhorten the tap root, but do not prune their tops.

The ſecond year after planting out, if they take to growing well, they will be fit to bud, if they are intended for dwarfs; but if they are for ſtandards they will not be tall enough till the fourth year, for they ſhould be budded or grafted near ſix feet from the ground, otherwiſe the graft will not advance much in height; ſo that it will be impoſſible to make a good tree from ſuch as are grafted low, unleſs the graft be trained upwards.

The uſual way with the nurſery-gardeners is, to bud their ſtocks in ſummer, and ſuch of them as miſcarry they graft the ſucceeding ſpring. Thoſe trees where the buds have taken, muſt be headed off the beginning of march about ſix inches above the bud; and when the bud has ſhot in ſummer, if there be any apprehenſion of its being blown out by the winds, it muſt be faſtened with baſs or other ſoft tying to that part of the ſtock which was left above the bud. The autumn following theſe trees will be fit to remove; but if the ground be not ready to receive them, they may remain two years before they are tranſplanted; in doing which obſerve not to head them, for this very often is immediate death to them; but if they ſurvive, they ſeldom recover in five or ſix years.

If theſe trees are intended for a wall, plant dwarfs between the ſtandards; but the latter, as the former fill the walls, muſt be cut away, to make room for them. But never plant ſtandard Cherries over other fruits; for there is no ſort of fruit that will proſper well under the drip of Cherries.

When theſe trees are taken up from the nurſery, ſhorten the roots, and cut off all the bruiſed parts, as alſo the ſmall fibres, which would dry, grow mouldy, and be a great prejudice to the new fibres in their coming forth; cut off likewiſe the dead part of the ſtock which was left above the bud, cloſe down to the back part of it, that the ſtock may be covered by the bud. If theſe trees are deſigned for a wall, place the bud directly from the wall, that the back part of the ſtock which was cut may be hid from ſight. The ſoil that Cherries thrive beſt in is a freſh hazel loam: if it be a dry gravel they will not live many years, and will be perpetually blighted in the ſpring.

The ſorts commonly planted againſt walls are the Early May and May Duke, which ſhould have a ſouth aſpect. The Hearts and common Duke will thrive on a weſt wall, and in order to continue the Duke later in the ſeaſon, they are frequently placed againſt north and north-weſt walls, where they ſucceed very well. The Morello, which is chiefly planted for preſerving, is commonly put on a north wall. The Hearts are all ill bearers, for which reaſon they are ſeldom planted againſt walls; but probably if they were grafted on the Bird Cherry, and managed properly, that defect might be remedied; for it is ſaid that this ſtock will render Cherries very fruitful, and having the ſame effect on Cherries as the Paradiſe ſtock has on Apples, they may be kept in leſs compaſs: at leaſt it is an experiment well worth the trial.

Cherry trees planted againſt a wall, ſhould be at leaſt twenty or twenty-four feet aſunder, with a ſtandard tree between each dwarf: for theſe trees will extend themſelves as far as, or farther than Apricots, and many other ſorts of fruit.

In pruning Cherries, the ſhoots ſhould never be ſhortened, for moſt of them produce their fruit buds at their extreme part, which by ſhortening are cut off, and this often occaſions the death of the ſhoot: their branches ſhould therefore be trained in at full length horizontally, obſerving in May, where there is a vacancy in the wall, to ſtop ſome ſtrong adjoining branches, which will occaſion their putting out two or more ſhoots; by which means, at that ſeaſon of the year, there may always be a ſupply of wood for covering the wall; at the ſame time diſplace all fore-right ſhoots by the hand, for if they are ſuffered to grow till winter, they will not only deprive the bearing branches of their proper ſupply of nouriſhment, but when they are cut out, they occaſion the tree to gum in that part; for Cherries bear the knife worſe than any other ſort of fruit-trees; but be careful not to rub off the ſides or ſpurs which are produced upon the two or three years old wood; for it is upon theſe that the greateſt part of the fruit is produced, and they will continue fruitful for ſeveral years. It is for want of duly obſerving this caution that Cherry-trees are often ſo unfruitful, eſpecially the Morello, which ſhoots the weaker, the more it is cut.

Cherry-trees are alſo planted for Orchards in many parts of England, particularly in Kent. The uſual diſtance allowed for them is forty feet ſquare, at which ſpace they are leſs ſubject to blight than when they are planted cloſer; and the ground may be tilled between them almoſt as well as if it were entirely clear, eſpecially whilſt the trees are young; and the often ſtirring the ground, provided the roots be not diſturbed, will greatly help the trees; but when they are grown ſo big as to overſhadow the ground, the drip of their leaves will not ſuffer many things to thrive under them.

The beſt ſorts for an Orchard, are the common Red or Kentiſh, the Duke and the Lukeward, all which are plentiful bearers.

Some perſons graft the Duke and other ſorts of Cherries upon the Morello, which is but a weak ſhooter, in order to check the luxuriant growth of their trees, which will ſucceed for three or four years; but they are not of long duration, nor will they make ſhoots above ſix or eight inches long; being cloſely covered with bloſſoms, they may produce ſome fruit in a ſmall compaſs; but ſuch experiments are unfit for general uſe, and proper only to ſatisfy curioſity; and it is much better to allow the trees a greater ſhare of room againſt the walls, when one tree ſo planted, and properly managed, will produce more fruit than twenty of theſe trees, or twice that number, when they are planted too cloſe, though they are grafted upon the Black Cherry, or any other free ſtock.

The double-flowering Cherry is propagated by budding or grafting on the Black or Wild Cherry ſtock; and the trees are very proper to intermix with flowering trees of the ſecond growth. The flowers are as large and double as a Cinnamon Roſe, and being produced in large bunches on every part of the tree, render it one of the moſt beautiful trees of the ſpring. Some of the flowers, which are leſs double, often produce fruit, which the very double flowers do not.

17. The Black Cherry is ſeldom grafted or budded, but is generally ſown for ſtocks; where perſons however are curious to have the beſt flavoured of this ſort of fruit, they ſhould be grafted from ſuch trees as produce the beſt. [They are always trained as ſtandards, the Coroun for the orchard, and the ſmall wild black and red for plantations in parks, &c.]

20. Plums. All the varieties are propagated by budding or grafting upon ſtocks of the Muſcle, white Pear, St. Julian, Bonum Magnum, or any of the free-ſhooting Plums. For the manner of raiſing theſe ſtocks, ſee Nursery.—Budding is much preferable to grafting for Plum-trees, becauſe they are very apt to gum, wherever large wounds are made on them.

The trees ſhould not be more than one year's growth from the bud when they are tranſplanted, for if they are older they are very ſubject to canker; or if they take well to the ground, commonly produce only two or three luxuriant branches.

The manner of prepairing the ground (if for walls) is the ſame as for Peaches; as is alſo pruning the roots and planting, therefore I ſhall forbear repeating it again. The diſtance which theſe trees ſhould be planted at, muſt not be leſs than twenty-four feet againſt high walls; and if the wall is low, they ſhould be placed thirty feet aſunder.

Plums ſhould have a middling ſoil, neither too wet and heavy, nor over light and dry, in either of which extremes they ſeldom do ſo well; and thoſe ſorts which are planted againſt walls, ſhould have an eaſt or ſouth-eaſt aſpect, which is more kindly to theſe fruits than a full ſouth aſpect, on which they are ſubject to ſhrivel, and be very dry; and many ſorts will be extreme mealy, if expoſed too much to the heat of the ſun; but moſt ſorts will ripen extremely well on eſpaliers, if rightly managed.

There are ſome perſons who plant Plums for ſtandards, in which method ſome of the ordinary ſorts will bear very well; but then the fruit will not be near ſo fair as thoſe produced on eſpaliers, and will be more in danger of being bruiſed or blown down by ſtrong winds. The diſtance of placing them for eſpaliers muſt be the ſame as againſt walls, as muſt alſo their pruning and management; ſo that whatever may be hereafter mentioned for one, ſhould be likewiſe underſtood for both.

Plums do not only produce their fruit upon the laſt year's wood, but alſo upon curſons or ſpurs, which come out of wood that is many years old; ſo that there is not a neceſſity of ſhortening the branches, in order to obtain new ſhoots annually, in every part of the tree (as in Peaches, Nectarines, &c. hath been directed) ſince the more theſe trees are pruned, the more luxuriant they grow, until the ſtrength of them is exhauſted, and then they gum and ſpoil; therefore the ſafeſt method to manage theſe trees is, to lay in their ſhoots horizontally, as they are produced, at equal diſtances, in proportion to the length of their leaves; and where there is not a ſufficient quantity of branches to fill up the vacancies of the tree, there the ſhoots may be pinched the beginning of May (in the manner as hath been directed for Peaches, &c.) which will cauſe them to produce ſome lateral branches to ſupply thoſe places; and during the growing ſeaſon, all fore-right ſhoots ſhould be diſplaced, and ſuch as are to remain muſt be regularly trained in to the wall or eſpalier, which will not only render them beautiful, but alſo give to each part of the trees an equal advantage of ſun and air; and hereby the fruit will be always kept in a ductile growing ſtate, which they ſeldom are, when overſhaded with ſhoots ſome part of the ſeaſon, and then ſuddenly expoſed to the air, by taking off, or training thoſe branches in their proper poſition.

With thus carefully going over theſe trees in the growing ſeaſon, there will be but little work to do to them in winter; for when the branches are ſhortened, the fruit is cut away, and the number of ſhoots increaſed; for whenever a branch is ſhortened, there are commonly two or more ſhoots produced from the eyes immediately below the cut; ſo that by thus unſkilfully pruning, many perſons crowd their trees with branches, and thereby render what little fruit the trees produce, very ſmall and ill-taſted; which is very commonly found in too many gardens, where the manager, perhaps, thinks himſelf a complete maſter of his buſineſs, for nothing is more common than to ſee every branch of a fruit-tree paſs the diſcipline of the knife, however diſagreeable it be to ſeveral ſorts of fruits. And it is common to ſee theſe trees planted at the diſtance of fourteen or ſixteen feet, ſo that the walls are in a few years covered with branches; and then all the ſhoots are cut and mangled with the knife, ſo as to appear like a ſtumped hedge, and produce little fruit; therefore the only way to have Plum-trees in good order,

is to give them room, and extend their branches at full length.

Thoſe few rules before laid down, will be ſufficient, if due obſervation be joined therewith, to inſtruct any perſon in the right management of theſe ſorts of fruit-trees.

21. [The Bullace is raiſed from the ſtones; but its varieties can be continued with certainty only by graffing or budding them upon any Plum or Bullace ſtocks.

The ſtones may be ſown in autumn in beds, two inches deep; keep them clean, and when they are two years old, plant them in rows from two to three feet aſunder, and train them to a ſingle ſtem.

Graft or bud theſe, when they are of a proper height, in the ſame manner as other Plums. When they have formed heads, tranſplant them where they are to remain, any time from october to march, placing them eighteen or twenty feet aſunder.

22. The Black-thorn, though very uſeful to the huſbandman, is alſo noxious to him, by incroaching on his paſturage. If they be felled above ground, the ſtubs are in the way of the ſcythe and the bite of cattle, and the thicket is preſently renewed.

If Black-thorns be grubbed up by the roots, every fibril left in the ſoil produces a freſh plant; ſo that unleſs great caution is obſerved in taking all theſe out, inſtead of being leſſened by this tedious and expenſive operation, their number will be increaſed.

But if they be cut off level with the ſurface, the ſcythe has free ſweep, and the young ſhoots are removed with eaſe and certainty.

If the ground be mown for hay, the ſame ſtroke which cuts the herbage takes off the ſhoots.

If paſtured; cattle and ſheep, provided they have no woodland left to browze among, will gnaw them to the quick. It is however always adviſeable in this caſe to ſweep the ground over with the ſcythe in the courſe of the ſummer, to remove the remains which may have eſcaped the bite of the animals.

The ſecond year the ſhoots will riſe weak, and the roots themſelves ſeldom ſurvive the third year.

In a very few years more the roots will be found entirely rotten.

If a thicket or border, where the ſward is nearly loſt, be treated in this manner, rubbiſh of every kind ſhould be raked off, a few graſs-ſeeds ſcattered on, and the ſurface run over with a roller, as a preparation for the ſcythe.

This mode of extirpation is applicable not only to the Black-thorn, but to every tree and ſhrub to which it has been applied, the Furze and Bramble excepted[1].

Where headlands or borders are grubbed, they ſhould be planted with Potatoes or ſome other cleanſing crop, that is well hoed, till the Black-thorns or other ſhrubs and hedge-weeds are totally eradicated, before they are laid down to graſs. Thus purſued grubbing more effectually anſwers the purpoſe than mowing.

Leaves oblong acuminate crenulate ſhining, peduncles many-flowered.

DESCRIPTIONS, *&c.*

1. In its wild ſtate the White Guava tree grows to the height of ſeven or eight, ſometimes of twelve feet. In gardens in the Weſt Indies, where the ſoil is good, it equals a middle-ſized Apple tree, the trunk being ſix feet in height, and a foot and half in circumference. Bark ſmoothiſh, of a yelloviſh browa colour, with large aſh-coloured ſpots. Wood very hard and tough, uſed for ox-yokes and the like purpoſes, and well adapted for fuel. Branches numerous, the young ones four-cornered. Leaves blunt, entire, ſmoothiſh, on ſhort petioles, two or three inches long, oppoſite. Peduncles ſolitary, ſhort, ſupporting a white ſweet-ſmelling flower. Fruit ſmooth, having a peculiar ſmell, yellow ſulphureous or whitiſh on the outſide, roundiſh or more oblong, the ſize of a hen's egg or bigger, according to the ſoil: the rind is a line or two in thickneſs, brittle and fleſhy; pulp rather firm, full of bony ſeeds, fleſh-coloured, ſweet, aromatic and pleaſant. This fruit is eaten with avidity, not only by the natives, but by Europeans; with thoſe who are not accuſtomed to it, the Guava is apt to occaſion a ſlight flux; but Jacquin affirms that when he has been thirſty on a journey, he has eaten of it to ſatiety without ſuffering any harm. It is eaten raw in the deſert, but the ſeeds are ſcarcely ſeparable. It is alſo preſerved with ſugar [a].

Loureiro ſays that the berry is two inches in diameter, commonly egg-ſhaped, but ſometimes roundiſh, ſeldom pear-ſhaped; the rind even and pale, the pulp fleſhy, white or red.

Native both of the Weſt and Eaſt Indies, Cochinchina and the ſouthern provinces of China; becoming a large tree when cultivated, but in its wild ſtate much ſmaller and of an irregular growth, with the trunk and branches diſtorted. In the Caribbee iſlands it frequently overruns the paſtures, and one tree in a garden will ſuffice to fill the whole; for the ſeeds paſs through the body of men and animals, without loſing their vegetative quality [b].

Cultivated here in 1656, by Mr. John Tradeſcant, junior [c].

2. This has exactly the appearance of the preceding, but is five times ſmaller in all its parts. It is a ſhrub of two feet in height, with four-cornered branches having an aſh-coloured villus on them. Leaves oppoſite, an inch long, quite entire, ſmooth above, villoſe underneath, ſeſſile or on very ſhort petioles. Peduncles from the extremities of the branchlets, in pairs, ſhort, villoſe. Leaflets of the calyx lanceolate, blunt, leathery, villoſe within. Fruit globular, the ſize of a hazel nut, ſubvilloſe.—Native of the iſland of Ceylon [d].

Willdenow ſuſpects that *P. caninum* of Loureiro may be the ſame with this; ſince they agree in general, except that he deſcribes the leaves as ſubferrate. He calls it *canina*, becauſe dogs are delighted with it in the ſame manner as cats are with Valerian.—Native of China about Canton.

Loureiro has two other ſpecies, natives of Cochinchina, in woods. 1. *P. nigrum*; a middle-ſized tree, with diſtorted, ſpreading branches. Leaves ovate-lanceolate, ſlightly ferrate, ſmooth on both ſides, ſcattered, without any nerves or ribs, dark green, ſhining. Flowers white, on many-flowered terminating peduncles. Berries black, very ſmall, round, crowned, one-celled, many-ſeeded. 2. *P. rubrum*; a middle-ſized tree with ſpreading branches. Leaves oblong, blunt, quite entire, ſmooth, oppoſite, on ſhort petioles. Flowers white, many, ſeſſile, heaped together, axillary. Calyx tubular, oblong, four-toothed, ſuperior. Petals four, ſmall, unequal. Berry calycine, oblong, red, one-celled, many-ſeeded, crowned, eatable, ſmall. It ſeems to belong to this genus, though it has one-fifth part leſs in the calyx and corolla.

3. This is a tree of moderate ſize, with a trunk of about five feet in height, and branching at the top in a ſcattered manner; the ſmaller branches are tetragonal and leafy; the leaves oblong-ovate, ſharp-pointed, ſmooth, perfectly entire, and ſtanding on ſhort footſtalks: the flowers ſolitary, oppoſite, and riſing from the boſoms of very ſhort leaves near the baſes of the ſmaller branches: they are white and are either tetrapetalous or pentapetalous. The fruit is aromatic, and eatable; a ſpherical berry, of a yellow colour, crowned with the toothlets of the calyx, and quadrilocular. The bruiſed leaves have the ſmell of Balm.—It is a native of Cayenne and Guiana, growing in woods, and flowering in the month of October.

4. This alſo is a middle-ſized tree, with a trunk ten feet high, branching in an irregular manner from the top; the ſmaller branches are quadrangular, and leafy; the leaves oppoſite, ſmooth, quite entire, ſomewhat footſtalked, and ovate-acuminate; they are more than four inches long, and about two and a half broad. The flowers ſpring from the young branches, and ſtand ſingly at the boſom of each leaf, except thoſe towards the top of the branches: their footſtalks are ſlender, and about two inches long: the petals are white, waved at the borders, and generally five in number: they have a very agreeable odour, and are ſucceeded by ſmooth yellow berries, having four cells, filled with ſmall ſeeds, enveloped in a ſucculent pulp.—It grows in the woods of Cayenne, flowering in december and bearing fruit in february [e].

5. This is a ſmooth ſhrub. Leaves petioled ſmall quite entire veined, not marked with lines. Peduncles axillary, half as ſhort again as the leaves, ſilky. One bracte or two, oblong. Flowers ſmall, white. Calyxes ſilky. Capſule or berry ſmall, globular, toruloſe, crowned with the permanent calyx [f].

Gærtner deſcribes the fruit as a ſubglobular berry, obſoletely toruloſe, fleſhy, one-celled, crowned by the five-toothed calyx, ending below in a very long peduncle, near the baſe of the fruit, accompanied by two, linear-acuminate, oppoſite, minute ſtipules. Seeds placed in a ring in a double row; in the upper row eight, in the lower twelve or more, all oblong, on one ſide convex, thick, bowed; on the other ſtraight, compreſſed into a wedge-form angle: in other parts ſomewhat bony, and of a pale teſtaceous colour.

It differs from Guajava only in having all the ſeeds inverted, inſtead of being in every poſition; in their being ſtraightiſh and not kidney-form; and in there being no partition whatever.—Native of Otaheite, and the other Society Iſles.]

6. The common red Guava has a pretty thick trunk, twenty feet in height, covered with a ſmooth bark, and dividing into many angular branches towards the top. Leaves two inches and a half long, and

[a] Jacquin. [b] Loureiro and Jacquin. [c] Hort. kew. [d] Vahl. [e] Aublet. [f] Linn. ſuppl.

one inch and a half broad in the middle, rounded at both ends, having a ſtrong midrib and many veins running towards the ſides, of a light green colour, oppoſite on very ſhort foot-ſtalks. Peduncles axillary, an inch and half long. Petals large and white. Fruit ſhaped like a Pomegranate, crowned, when ripe having an agreeable odour.

[According to Jacquin it agrees in habit with the the firſt ſpecies, and differs principally in being of a paler colour both in the rind and pulp, and having an acid flavour or none at all. The form is the ſame. It is not ſo common; and is ſcarcely ever eaten. In Martinico it is called *Goyavier de Cayenne*; the firſt ſpecies *Goyavier du pays*.

Loureiro deſcribes it as a diſtorted and very branching ſhrub, four feet high. Leaves quite entire, ſmall, wrinkled, rugged, ſeſſile, oppoſite, with oblique, parallel ribs. Flowers white, ſmall, ſcattered, from one to three on longiſh peduncles. Berry an inch in diameter or leſs, ſubglobular, ſmooth, within white or red.

Native both of the Weſt and Eaſt Indies, China and Cochinchina in woods. In the latter countries, according to Loureiro, the fruit is eatable, but bad, neither taſte nor ſmell being pleaſant. The root and young leaves are aſtringent, and eſteemed uſeful in curing fluxes, and ſtrengthening the ſtomach.

Introduced here in 1692, by the Dutcheſs of Beaufort[a].

7. Native of Prince's iſland on the coaſt of Guinea, and cultivated in Domingo[b].

8. This is one of the largeſt trees in the woods of Jamaica, growing frequently to the height of ſixty or ſeventy feet, with a proportioned thickneſs: it is an excellent timber wood, of a dark colour and curled grain; works eaſily, and takes a fine poliſh. It makes very beautiful walking-ſticks[c].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which muſt be procured from the countries where they naturally grow; if theſe are brought over in the entire fruit, gathered full ripe, the ſeeds will more certainly ſucceed; theſe ſhould be ſown in pots filled with rich kitchen-garden earth, and plunged into a hot-bed of tanners-bark, giving them water from time to time as the earth dries; in about ſix weeks the plants will appear (if the ſeeds are good) and muſt have free air admitted to them in proportion to the warmth of the ſeaſon; when the plants have obtained ſtrength enough to be removed, they ſhould be each planted in a ſmall pot, filled with the like rich earth, and plunged into a freſh hot-bed, ſhading them from the ſun until they have taken new root; then they ſhould have a large ſhare of free air admitted to them every day in warm weather, to prevent their drawing up weak; they muſt alſo be frequently refreſhed with water in ſummer. When the plants have filled theſe ſmall pots with their roots, they ſhould be ſhaken out and their roots pared, then put into larger pots filled with the ſame ſort of earth, and plunged into the hot-bed again, where they ſhould remain till autumn, when they muſt be plunged into the tan-bed in the ſtove: during the winter they ſhould have a moderate warmth, and not too much water, and in ſummer they will require plenty of wet, and in hot weather a great ſhare of air; with this management the plants will produce flowers and fruit the third year, and may be continued a long time.

PSORALEA, (ψωραλεος, *ſcabioſus*; *the calyx and great part of the plant being dotted with tubercles.*)
Lin. gen. n. 894. *Reich. n.* 967. *Schreb. n.* 1210. *Roy. lugdb.* 372. *Gærtn. t.* 145. *Juſſ.* 355. Dalea *edit. prior.*

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leaſed, dotted with tubercles, five-cleft: *ſegments* acute, equal, permanent; the loweſt double the length of the others.

COR. papilionaceous, five-petalled. *Standard* roundiſh, emarginate, riſing. *Wings* creſcent-ſhaped, blunt, ſmall. *Keel* two-petalled, creſcent-ſhaped, blunt.

STAM. *Filaments* diadelphous, (one ſingle and briſtle-ſhaped, nine united) aſcending. *Anthers* roundiſh.

PIST. *Germ* linear. *Style* awl-ſhaped, aſcending, the length of the ſtamens. *Stigma* blunt.

PER. *Legume* the length of the calyx, compreſſed, aſcending, acuminate.

SEED ſingle, kidney-form.

OBS. *It is ſingular in this genus, that the calyx, as alſo the whole plant, is dotted with tubercles, and the petals marked with coloured veins.*

ESSENTIAL CHARACTER.

Calyx beſprinkled with callous dots, the ſame length with the *Legume*, which has only one ſeed in it.

Mill. dict. n. 7.
Barba Jovis amer. humilis rotundifolia & villoſa, flore vario. *Houſt. MSS.*
Leaves pinnate with rounder villoſe leaflets, flowers in axillary and terminating heads, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

[1. Native of the Cape of Good Hope; found there by Thunberg[d].]

2. This riſes with a ſoft ſhrubby ſtalk, four or five feet high, dividing into ſeveral branches. Leaves of a deep green colour, compoſed of three or four pairs of very narrow leaflets, terminated by an odd one, ſtanding upon ſhort foot-ſtalks, and coming out without order on every ſide of the branches. The flowers ſit very cloſe to the branches, and are often in cluſters: the ſtandard, which is erect and reflexed at the top, is of a fine blue; the wings are pale, and the keel white.

[According to the obſervation of Linneus; the peduncles are axillary, ſolitary, glumeleſs and hirſute.]

It flowers during great part of the ſummer, and the ſeeds ripen in autumn. It grows naturally at the Cape of Good Hope; whence Mr. Miller frequently received the ſeeds: but it was cultivated in 1690, in the Royal Garden at Hampton Court[e].

3. This is a ſhrub with angular branches, and lateral ſolitary flowers without bractes.

Native of the Cape of Good Hope, by ditches[f]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in june and july[g].

4. Stem ſhrubby, determinately branched, with round pubeſcent branches. Leaves ſeſſile: leaflets even, dotted, pointed at the end with a patulous ſpine. Stipules chaffy, lanceolate, acuminate, ciliate. Spikes terminating, ſolitary, ſubvilloſe, peduncled. Flowers ſeparated by ovate acuminate ciliate bractes, almoſt the length of the flowers. Corolla violet-coloured, with a white keel having a violet ſpot in front. Calyxes hairy, with linear teeth; except the loweſt tooth, which is ovate and larger.

[d] Linn. ſuppl. [e] Hort. kew. [f] Linn. mant. [g] Hort. kew.

Native of the Cape of Good Hope [b]. Cultivated in 1731, by Mr. Miller. It flowers in june and july [i].

5. Stem ſhrubby, with alternate round erect pubeſcent branches. Leaves on very ſhort petioles. Leaflets dotted, obſoletely pubeſcent, ſometimes having a minute weak point; the middle one longer than the other two. Stipules narrow, ſcarcely longer than the petiole. Spikes longer, ſeſſile, ſolitary. Flowers blue, ſeparated by linear ſcarioſe bractes, ſcarcely the length of the calyx. Calyxes pubeſcent, with ſhort, almoſt equal, awl-ſhaped, blunt teeth.

Native of the Cape of Good Hope [k]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in july [l].

6. Native of the Cape of Good Hope, where it was found by Mr. Maſſon, and introduced in 1774. It flowers from may to auguſt [m].

7. This is ſingular with its filiform one-flowered peduncles.—Native of the Cape of Good Hope, where it was found by Thunberg.

8. Stem hirſute. Calyx brown, extremely villoſe. Corolla ferruginous.—Native of the Cape of Good Hope [n].

9. This is a ſhrub with lateral ſubterminating flowers. Leaves linear-lanceolate, deciduous.—Native of the Cape of Good Hope [o].

10. Peduncles axillary, ſolitary, glumoſe. In others the peduncles are lateral, cluſtered and capillary, the length of the leaves. Bractes two, briſtle-ſhaped, in the middle of the peduncle.—Native of the Cape of Good Hope [p].

11. Branches ſtriated. Leaves petioled, a finger's length, with ſcarcely conſpicuous dots very cloſely cluſtered ſcattered over them on both ſides: the uppermoſt ſimple. Head of flowers roundiſh, ſurrounded commonly with three ſimple linear leaves. Standard dotted like the leaves.

Native of the Cape of Good Hope, where it was found by Thunberg [q].

12. This is a ſhrub, with rough-haired rigid branches. Leaves petioled: leaflets ſubpetioled, ſubpubeſcent. Flowers at the ends of the branches: calyxes pubeſcent; corollas violet-coloured.—Native of the Cape of Good Hope [r].

Cultivated in 1713, by the Dutcheſs of Beaufort. It flowers moſt part of the ſummer [s].

13. Native of the Cape of Good Hope, where it was found by Mr. Francis Maſſon, who introduced it in 1774. It flowers in april and may [t].

14. Stems rooting, ſomewhat woody, much branching and very long. Leaves petioled: leaflets obovate, dotted, blunt, naked, ſeſſile: petioles the length of the leaflets. Stipules minute, ovate, acute. Umbels ſeſſile, unequal, lateral and terminating. Flowers blue.—Native of the Cape of Good Hope [u].

15. Root perennial, but the ſtalk not of long duration, ſeldom laſting more than two years: it riſes about two feet high, ſending out two or three ſlender branches. Leaflets about two inches long, and one inch and a quarter broad, on long foot-ſtalks. The leaves, if handled, emit a ſtrong ſcent of bitumen. The heads of flowers are on axillary peduncles ſeven or eight inches long. The corollas are blue.

[Stem ſuffruticoſe. Spikes roundiſh. The tenth ſtamen diſtinct, as in *P. glandulosa* and *americana*. It varies with lanceolate and ovate leaves [x].

Calyx ſtriated, with the ſegments acuminate, of the ſame length with the corolla. Standard oblong, purple; wings ſhorter, diſtant, almoſt white; keel yet ſhorter, bifid, purple at top. The flowers ſmell like Black Currants.

Legume ſmall, with an ovate belly ending in a long acuminate beak; the lower part the length of the tube of the calyx, compreſſed like a lens; above hiſpid with rigid diverging briſtles, below ſprinkled with brown-cheſtnut dots on an ochre ground; very thin, adhering ſo cloſe to the ſeed, that it cannot be

[u] Linn.

ſeparated but by ſcraping it off: beak half as long again as the belly, membranaceous, compreſſed like a leaf, ſabre-ſhaped, ſtraw-coloured, apt to fall off. Seed obovate-reniform, lenticular, ſmooth, dark-coloured and ſhining [y].

Native of Italy, Sicily, the South of France and Barbary.—It was cultivated here in 1570, as appears from Lobel; and flowers moſt part of the ſummer [z]. Gerarde ſays, in Engliſh it is called *Clover gentle*, *Pitch Trefoil*, *ſtinking Trefoil*, and *Treacle Clover*.]

β. The leaves of this are much longer and narrower, and are rounded at their baſe; the ſtalks are ſhrubby, and of longer duration; the heads of flowers are ſmaller, and the leaves have not ſo ſtrong an odour.

It grows naturally in Sicily, and alſo in Jamaica, from both which countries Mr. Miller received the ſeeds; from which he propagated this and the preceding many years, and never found them to vary.

[16. Stem ſuffruticoſe. It reſembles *P. americana*; but the elongated ſpikes are almoſt racemed, with very ſmall bractes, not the length of the calyx. It has the ſmell of Rue [a].

The two inner leaflets are leſs and ſubſeſſile, the end one is larger on a long petiole. The common petiole is a little longer than the larger leaflet; that and both ſurfaces of the leaves have glands ſcattered over them. Stipules very ſmall, briſtle-ſhaped. On the lower leaves the leaflets are blunt; but on the upper ones they are acute, narrower and a little longer. Peduncles equal to the leaves or a little longer, full of glands. Flowers from twelve to twenty-ſix, ſome alternate, others two or three together, on very ſhort pedicels. Calyxes glandular, twice as big as in *P. coryliſolia*, and only half the ſize of thoſe in *P. bituminoſa*. Corollas ſmall, with the wings and keel white, and the ſtandard blue. Bractes none; but the pedicels ſupported on a little prominent callus [b].

Native of Peru, Spain and the iſlands of Majorca and Minorca.—Introduced about 1770. It flowers from may to auguſt [c].

17. Stem herbaceous, leaves hairy. Petioles with many ſtreaks. Stipules patulous. Heads depreſſed. Bractes aſh-coloured. Flowers violet-coloured, large [d].

Stem flexuoſe, two feet high, ſtriated, with joints an inch from each other, hairy, hoary-aſh-coloured. Branches ſhort, ſpreading. Leaflets of the lower leaves ſuborbicular, eſpecially the odd one, and ſomewhat hiſpid; thoſe of the upper leaves lanceolate, acuminate at both ends: petioles from an inch to an inch and half in length, more hoary with hairs towards the top. Stipules ſetaceous-ſubulate, hirſute, longer and narrower than in *P. bituminoſa*, although the plant itſelf be ſmaller. Peduncles twice as long as the leaves, rigid, hirſute. Flowers from nine to twelve in a head. Bractes ovate, concave, palmate-trifid, acuminate. Calyxes five-cleft to the middle, ventricoſe, and more widened than in *P. bituminoſa*. Corollas blue. Legume ovate, hirſute, ſhorter than the calyx, terminated by a long ſtraight enſiform dagger-point, exceeding the calyx [e].

Native of the Levant. Introduced in 1771, by Joſeph Nicholas de Jacquin, M. D. It flowers moſt part of the ſummer [f].

18. Stems diffuſed, herbaceous, with glandular dots ſcattered over them. Leaflets roundiſh, very blunt, obſoletely toothed or angular, ſprinkled with glandular dots; the middle one larger and petioled. Spikes axillary, oblong, on peduncles the length of the leaves [g].

Native of Madeira. Cultivated here in 1640, as appears from Parkinſon [h], who ſays, that becauſe it flowers late, it often miſſes to give good ſeed, whereby we are often to ſeek for it again. Linnæus relates that he had not ſeen it in the European gardens.

19. Stem herbaceous, erect, flexuoſe, angular, the thickneſs of a quill. Leaves the ſize of Melilot or

[y] Gaertner.
[z] Hort. kew.

[h] Hort. kew.

larger: leaflets ovate, acuminate, thinly and deeply ſerrate, or ſlightly toothed, ſcarcely pubeſcent on both ſides; the odd leaflet petioled. Stipules briſtle-ſhaped. Racemes axillary, erect, peduncled, the length of the leaves. Bractes briſtle-ſhaped, commonly longer than the flower. Flowers alternate, on very ſhort pedicels, a little larger than thoſe of *Indigofera*, having an acute keel without the lateral horns of that plant. Legumes large, the length of the leaves, compreſſed, with each ſuture membranaceous-angular on both ſides, terminating in an elongated point. Seeds four or five. Perhaps it may be a ſpecies of *Indigofera*. Found in Arabia by Forſkahl, and at Suratte by Brad[t].]

20. This is an annual plant. The ſtalks riſe two feet high, and have at each joint one leaf about two inches long, and an inch and a half broad, having one ſtrong midrib, from which come out ſeveral veins, that run towards the top of the leaf. The flowers are produced on long ſlender axillary peduncles, are collected into ſmall round heads, and are of a pale fleſh colour. It grows naturally in India, and flowers here in july; the ſeeds ripen in autumn. [It was cultivated in 1752 by Mr. Miller[x].

The upper leaves are ſometimes ternate, both in Forſkahl's and Koenig's ſpecimens. And in the plants that roſe from Koenig's ſeeds, ſome had ſimple leaves only, others had both them and ternate leaves[t].

21. Little is known of this ſpecies; nor is it certain whether it be a native of Mexico or Malabar.

22. This recedes in habit from the other ſpecies. Stems decumbent, filiform. Stipules erect. The middle leaflet is trifid; the partial ones pinnate; the leaflets linear; the peduncles axillary, the racemes roundiſh, and the flowers yellow[u].—Native of the Cape of Good Hope.]

23. This is an annual plant, with a very branching herbaceous ſtalk, riſing a foot and half high, ſpreading wide on every ſide. Leaves compoſed of five or ſix pairs of narrow wedge-ſhaped leaflets, terminated by an odd one. The flowers are collected in cloſe oblong ſpikes at the ends of the branches; they are ſmall and of a bright blue colour. Diſcovered by Dr. Houſtoun at Vera Cruz in New Spain.

[Linneus remarks that the leaflets have glandular dots ſcattered over them underneath; and that the ſpike of flowers is cloſe, as in Plantain.

Cultivated by Mr. Miller before 1733.

24. This is an upright ſlender ſhrub, five feet high, with few pliant branches. Leaves alternate, one or two inches long: leaflets at moſt five, obovate or oval, emarginate, ſmooth, petioled, oppoſite, four or five lines long, with little bags on the back that appear like dots, as in *Hypericum perforatum*, containing a gummy juice of an unpleaſant ſmell: if rubbed, they ſtain the fingers of a yellow colour, which can hardly be waſhed out, and tinge water of a very beautiful clear yellow, gradually becoming deeper. Spikes denſe, ſolitary, on ſhort peduncles almoſt the length of the leaves. Flowers ſmall, red, ſeſſile, with the calyx not dotted. All the ten filaments are united. This plant ſeems nearly to unite Pſoralea with Ebenus.

Native of New Spain, about Carthagena, in coppices; flowering in may and the following months[x].

Introduced in 1772, by Monſ. Richard[y]. In the Kew catalogue it is ſaid to be an annual, a native of the Weſt Indies, and to flower here in july and auguſt.

25. This is a ſhrub with even ſtriated purple branches. Leaflets lanceolate, even, ſeven, ſcarce apparently dotted underneath. Stipules none, but a ſcarcely viſible ſharpiſh tubercle on each ſide inſtead of it. Flowers purple, not ſtriated. Pollen golden ſhining. It differs from *P. pinnata* in having the leaves not half a palm in length, linear, acuminate, pubeſcent, dark-ſpotted; the ſtipules not chaffy; the branches not pubeſcent; the calyxes not brown; the corollas not ſtriated.

Native of the Cape of Good Hope, where it was found by Thunberg[z].

[t] Linn. mant. [x] Hort. kew. [y] Vahl.
[u] Linn. amoen. [x] Jacquin. [z] Hort. kew.
[y] Linn. ſuppl.

26. Root annual. Stem ſmooth, ſtriated. Leaves ſcattered unequally pinnate. A ſingle leaf has often thirty pairs of leaflets, on very ſhort pedicels, quite entire, bluntiſh with a ſhort point, ſmooth, dotted underneath, ſcarcely half an inch in length. Spikes axillary, ſolitary, cylindrical, ſcarcely two inches long; on peduncles a finger's length, having frequently a ſmall pinnate leaf on them. Calyx rough with long villoſe hairs, three lines in length. Corolla blue with a white baſe: ſtandard ovate, entire; wings ovate, a little longer; keel of the ſame length with the wings: claws of all the petals filiform, a little ſhorter than the calyx, ſubconnate. Filaments united into a ſheath, cloven above, and longer than the calyx. Germ ovate, compreſſed a little, bearded at top with long villoſe hairs. Style on one ſide of the germ, erect, filiform, a little longer than the ſtamens. Legume turbinate-roundiſh, compreſſed, membranaceous, pellucid, a line in diameter, ſomewhat hairy. Seed ſmooth, brown-aſh-coloured[t].

Cavanilles's deſcription of his *P. Lagopus* agrees with the above ſo exactly, that there can be no doubt of their being the ſame plant.

The ſtems, according to him, are four feet high, with branches ſcattered alternately. Leaves alternate, with from thirty-three to thirty-ſeven pinnules, which are ovate-oblong: common petioles round, turgid at the baſe. Stipules inſerted into the petiole, very ſhort, awl-ſhaped, brown, deciduous. Flowers in very cloſe terminating ſpikes. Calyx turbinate, ſmooth at bottom, half-five-cleft; ſegments awl-ſhaped, dotted with brown, hairy. Corolla violet-coloured, with the petals approximating: ſtandard concave, with a long capillary claw; wings and keel, as four ovate petals, faſtened, not to the bottom of the calyx, but to the tube of ſtamens, by ſhort claws. Tube of the ſtamens whitiſh, ſurrounding the germ at the baſe, afterwards ſupporting the wings and keel, finally ending in ten ſtraight filaments. Legume very ſmall, ovate-reniform.

Native of Mexico. Its common name is *Terciopelillo*. Cavanilles ſaw it in flower, in the royal garden near Madrid in november[t].—It was introduced here by Benjamin Bewick, Eſq. in 1780, and flowers in october and november[t].

27. Stem round, ſmooth, having ferruginous glands ſcattered over it, branched. Leaves ſcattered, unequally pinnate. Each leaf has from ten to fourteen pairs of leaflets, on very ſhort petioles, oblong, acute, ſmooth, two lines in length. Spikes many-flowered, ſcarcely half an inch in length. Under each flower is an ovate concave bracte, the length of the calyx; which is pitcher-ſhaped, compreſſed, ſomewhat villoſe, two lines long. Corolla purple, pale at the baſe: ſtandard roundiſh, acute; wings oblong, longer than the ſtandard; keel the length of the wings. Filaments united into a ſheath cloven at top. Germ ovate, compreſſed, pubeſcent. Style filiform, longer than the ſtamens. Legume roundiſh, obliquely acuminate, compreſſed, pubeſcent. Seed compreſſed. It is an annual plant; and was introduced in 1786, by Benjamin Bewick, Eſq. but from what country is unknown. It flowers in october and november[t].

28. Stems round, hardiſh, branched, annual, ſcarcely a foot in length. Leaves ſcattered, unequally pinnate, with from ſeven to thirteen pinnules, which are ſubſeſſile, lanceolate, glaucous underneath, ſparingly villoſe, with brown protuberant dots. Stipules faſtened to the petiole, villoſe, briſtle-ſhaped. Spike of flowers an inch long, very villoſe; each flower ſeſſile, ſupported by a bracte which from bowed becomes erect, villoſe, variegated with brown dots. Calyx very ſmall, tubular, half-five-cleft; ſegments awl-ſhaped, hairy, dotted. Corolla pale violet, a little longer than the calyx: ſtandard ovate, plaited, with a white ſpot on each ſide, near the capillary claw; wings ovate, creſcent-ſhaped below, ſhorter than the ſtandard; keel longer than the ſtandard, two-petalled, ovate. Filaments all united; anthers roundiſh, brown. Germ

[t] Hort. kew. [t] Cavan. hiſp. [t] Hort. kew.
[t] Idem.

ovate,

ovate, villose at top. It is distinguished from the other species by the keel being longer than the petals.

Native of Mexico. Introduced into the royal garden near Madrid[a].]

29. Stem three or four feet high, sending out a few side branches. Leaflets hairy, on slender foot-stalks. Corollas purplish. Discovered by Dr. Houstoun at Vera Cruz, and cultivated by Mr. Miller before 1733.

30. This is an annual plant with trailing stalks about eight inches long. Leaflets three or four pairs besides the odd one, narrow, silvery. Flowers small, purple, in small clusters.—Native of Malabar.

31. Stems slender, shrubby, climbing to the height of six or seven feet. Leaflets three pairs besides the odd one, small, ovate, obtuse. Flowers small, bright blue, in small clusters. Discovered by Dr. Houstoun at Campeachy.

32. Stem seven or eight feet high, sending out many long slender branches on every side. Leaflets small and wedge-shaped. Flowers in small close heads, on pretty long peduncles. Corollas blue. Discovered by Dr. Houstoun at Campeachy.

33. This has an upright stem five or six feet high, with a few side branches. Leaflets three or four pairs, small, roundish, hairy. Flowers yellow and red intermixed, in small heads. Found by Dr. Houstoun at Vera Cruz.

PROPAGATION AND CULTURE.

2. This is easily propagated by seeds sown upon a moderate hot-bed. When the plants come up, they should have much air, and little heat. When of a size to remove, plant them in separate small pots, filled with light earth. Plunge them into the bed, shade them from the sun till they have taken new root, and gradually inure them to the open air; into which remove them about the end of may, and keep them abroad till october; then place them in the greenhouse. It may also be increased by cuttings, planted during any of the summer months, on a bed of light earth, covering them close with bell or hand-glasses, shading them, and gently refreshing them with water as the ground dries: when they have taken root, harden them gradually, transplant them into small pots, and treat them like the seedling plants.

15. This is also propagated by seeds, which should be sown on a bed of light earth in april: in may the plants will come up, when they should be kept clean from weeds, and as soon as they are fit to remove, transplant them. It will live through a favourable winter, in a warm dry border; but it is generally sheltered in a green-house or glass case.

20. Sow the seeds upon a hot-bed in the spring: when the plants are fit to remove, plant them in separate small pots filled with light earth, plunge them into a moderate hod-bed of tanner's bark, and shade them till they have taken new root; after which admit air to them freely in warm weather, and water them gently as often as they require it. When the plants have filled the pots with their roots, remove them into larger, and at the beginning of july remove them into an airy glass case, where they may be defended from cold, but have free air in warm weather; with this care the plants will flower and ripen their seeds.

23. 24. 26. 27. 28. 29 to 33. Sow the seeds on a hot-bed, and treat them, when they come up, in the same way as other plants from hot countries. Keep those sorts which are perennial in a moderate warmth in the stove during winter, in summer giving them a good share of free air. Some of them will sometimes ripen their seeds in England.

[1 to 14. 22. 25. Being natives of the Cape require only the protection of a greenhouse or glass case. They may be increased by seeds or cuttings, and should be treated as directed for n. 2.

PSYCHOTRIA. (*Altered by Linneus from* Psychotrophum, *the name which was given it by Browne, from* ψυχτριφον, *the name of an herb in Dioscorides, so called from its delighting to grow in cold situations.*)

[a] Cavanilles.

Lin. gen. n. 229. *Reich. n.* 246. *Schreb. n.* 313. *Juss.* 204. Psychotrophum. *Brown. jam. t.* 17. *f.* 2. *Jacqu. amer.* 65. *Gærtn. t.* 25.

Class. 5. 1. Pentandria Monogynia.

Nat. order of *Stellatæ. Rubiaceæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* very small, five-toothed, superior, permanent.

COR. monopetalous, salver-shaped (or funnel-shaped): *tube* long: *border* short, five-cleft: *segments* subovate, acute.

STAM. *Filaments* five, capillary. *Anthers* linear, not exceeding the tube.

PIST. *Germ* inferior. *Style* filiform. *Stigma* bifid, with the segments thickish, blunt.

PER. *Berry* roundish, (ovate or oblong) one-celled (two-celled, *G.*) crowned with the calyx.

SEEDS two, hemispherical (or oblong,) on one side convex and five-grooved, on the other flat.

ESSENTIAL CHARACTER.

Cal. five-toothed, crowning. *Cor.* tubular. *Berry* globular. *Seeds* two, hemispherical, grooved.

SPECIES.

1. Psychotria asiatica.
   Lin. spec. 245. *Syst.* 214. *Reich.* 1. 477. *Willd.* 961. *amoen.* 5. 395. *Swartz obs.* 74. *Gærtn. fruct.* 1. 120. *Brown. jam.* 160. *t.* 17. *f.* 2. *fec. Gærtn. v. n.* 8.
   Stipules emarginate, leaves lanceolate-ovate.
2. Psychotria glabrata.

Myrti folio arbor, &c. *Sloan. jam.* 2. 102. *Raii dendr.* 66.
Stipules ovate deciduous, leaves lanceolate-ovate nerveleſs ſhining rigid, branches directed one way, racemes compound terminating.

15. Pſychotria laxa.
Lin. ſpec. ed. Willd. 965. *Swartz deſcr.* 407.
Stipules ovate acute deciduous, leaves ovate acuminate, racemes in threes, terminating trichotomous, branches and pedicels ſubcapillary looſe.

16. Pſychotria paraſitica.
Lin. ſpec. ed. Willd. 965. *Swartz prodr.* 44. *deſcr.* 408.
Viſcoides pendulum. *Jacqu. amer.* 73. *t.* 51. *f.* 1.
Stipules embracing retuſe, leaves ovate acuminate veinleſs ſomewhat ſucculent, racemes terminating or axillary compound.

17. Pſychotria horizontalis.
Lin. ſpec. ed. Willd. 965. *Swartz prodr.* 44. *deſcr.* 410.
Stipules ovate, leaves lanceolate-ovate acute, branches leaves and branchlets of the panicles horizontal.

18. Pſychotria nutans.
Lin. ſpec. ed. Willd. 965. *Swartz prodr.* 43. *deſcr.* 411.
Stipules two-toothed, leaves lanceolate acute nerved, racemes three-parted erect, in their fruiting ſtate nodding.

19. Pſychotria ſpecioſa.
Lin. ſpec. ed. Willd. 965. *Forſt. prodr. n.* 89.
Arboreous, leaves oblong-lanceolate, involucre terminating ſubtriflorous.

20. Pſychotria involucrata.
Lin. ſpec. ed. Willd. 965. *Swartz deſcr.* 413.
Nonatella officinalis. *Aubl. guian.* 1. 182. *t.* 70. *f.* 1.
Stipules two-toothed, leaves lanceolate-ovate ſhining, racemes terminating corymbed, pedicels three-flowered, flowers involucred.

21. Pſychotria flexuoſa.
Lin. ſpec. ed. Willd. 966.
Nonatella paniculata. *Aubl. guian.* 1. 184. *t.* 70. *f.* 2.
Stipules two-toothed, leaves ovate attenuated to both ends, panicle divaricating flexuoſe.

22. Pſychotria racemoſa.
Lin. ſpec. ed. Willd. 966.
Nonatella racemoſa. *Aubl. guian.* 1. 186. *t.* 72.
Stipules two-lobed, leaves oblong acuminate, raceme terminating ſimple, flowers involucred.

23. Pſychotria violacea.
Lin. ſpec. ed. Willd. 966.
Nonatella violacea. *Aubl. guian.* 1. 188. *t.* 73.
Stipules oblong blunt deciduous, leaves oblong acuminate, flowers panicle-corymbed involucred.

24. Pſychotria brachiata.
Lin. ſpec. ed. Willd. 966. *Swartz prodr.* 45. *deſcr.* 415.
Stipules ovate bifid, raceme terminating compound, branches brachiate, flowers aggregate ſeſſile.

25. Pſychotria grandis.
Lin. ſpec. ed. Willd. 966. *Swartz prodr.* 43. *deſcr.* 417.
Stipules deltoid revolute at the edge awl-ſhaped at the tip, leaves cuneiform-obovate, ſtem angular.

26. Pſychotria patens.
Lin. ſpec. ed. Willd. 967. *Swartz prodr.* 45. *deſcr.* 419.
Stipules two-toothed, leaves diſtich lanceolate-ovate membranaceous, branches ſpreading, panicles directed one way.

27. Pſychotria uliginoſa.
Lin. ſpec. ed. Willd. 967. *Swartz prodr.* 43. *deſcr.* 421.
Pſychotrophum fruticoſum fol. venoſis ovatis oppoſitis, petiolis ſtipulatis, racemis terminalibus, baccis compreſſis. *Brown. jam.* 160. *n.* 1?
Stipules connate acute convex, leaves lanceolate-oblong, ſeeds compreſſed creſted, ſtem ſubherbaceous ſimple erect.

28. Pſychotria ſerpens.
Lin. ſyſt. 214. *Reich.* 1. 477. *Willd.* 967. *mant.* 204.
Stem ſubherbaceous creeping, leaves ovate acute at both ends.

29. Pſychotria herbacea.
Lin. ſpec. 245. *ſyſt.* 214. *Reich.* 1. 478. *Willd.* 967. *Jacqu. amer.* 66. *t.* 46. *pict.* 37. *t.* 67. *Swartz obſ.* 74.

Karinta-kali. *Rheed. mal.* 10. 41. *t.* 21. *Raii ſuppl.* 358.
Stem herbaceous creeping, leaves cordate petioled.

30. Pſychotria emetica.
Lin. ſyſt. 214. *ed. Willd.* 968. *ſuppl.* 144.
Ipecacuanha. *Woodv. med. bot.* 562. *t.* 203. *Piſ. braſ.* 101? *Marcgr. braſ.* 17?
Herbaceous, procumbent, leaves lanceolate ſmooth, ſtipules extrafoliaceous ſubulate, heads axillary peduncled few-flowered.

31. Pſychotria corymboſa.
Lin. ſpec. ed. Willd. 969. *Swartz prodr.* 44. *deſcr.* 423.
Stipules two-toothed, leaves lanceolate-ovate acute ſubrigid ſhining, flowers in corymbs, peduncle and pedicels coloured.

32. Pſychotria pubeſcens.
Lin. ſpec. ed. Willd. 969. *Swartz prodr.* 44. *deſcr.* 425.
Stipules two-toothed, leaves lanceolate-ovate acuminate pubeſcent, panicles cymed ſpreading.

33. Pſychotria pedunculata.
Lin. ſpec. ed. Willd. 969. *Swartz prodr.* 44. *deſcr.* 427.
Stipules two-toothed, leaves ovate-lanceolate ſomewhat wrinkled, flowers in a ſert of cyme, common peduncle elongated.

34. Pſychotria crocea.
Lin. ſpec. ed. Willd. 969. *Swartz prodr.* 44. *deſcr.* 429.
Pſychotrophum fruticoſum, fol. ovatis venoſis, racemis terminalibus croceis. *Brown. jam.* 160. *t.* 13. *f.* 1, 2. *quoad flores.*
Stipules two-toothed, leaves ovate acute nerved, panicles erect and peduncles ſaffron-coloured.

35. Pſychotria alpina.
Lin. ſpec. ed. Willd. 970. *Swartz prodr.* 44. *deſcr.* 431. *obſ.* 77.
Stipules two-toothed, leaves lanceolate-ovate membranaceous netted-veined, panicles erect, corollas elongated diaphanous.

36. Pſychotria paniculata.
Lin. ſpec. ed. Willd. 970.
Chiococca paniculata. *Lin. ſuppl.* 145.

Stipules two-toothed, leaves ovate, panicle erect, ſtem arboreous.

37. Pſychotria Palicurea.
Lin. ſpec. ed. Willd. 971. *Swartz deſcr.* 433.
Palicourea guianenſis. *Aubl. guian.* 1. 173. *t.* 66.
Stephanium. *Lin. gen. ed. Schreb. n.* 308. & *p.* 822.
Stipules two-lobed, leaves broad-ovate acuminate at both ends, panicles erect, corollas cylindrical ventricoſe ſomewhat curved mealy on the outſide.

38. Pſychotria lutea.
Lin. ſpec. ed. Willd. 971.
Nonatelia lutea. *Aubl. guian.* 1. 190. *t.* 74.
Stipules two-lobed, leaves broad-ovate acuminate, panicles erect, tube of the corolla narrowed at the baſe, ſegments of the border acute.

39. Pſychotria longiflora.
Lin. ſpec. ed. Willd. 971.
Nonatelia longiflora. *Aubl. guian.* 1. 185. *t.* 71.
Stipules two-lobed, leaves ovate-lanceolate acuminate, raceme terminating almoſt ſimple, tube of the corolla curved in, ſegments of the border bluntiſh.

DESCRIPTIONS, &c.

1. Native of the Eaſt Indies.—Gærtner affirms that the fruit of the Jamaica plant is as like to that of Ceylon as one egg is to another. He thus deſcribes it —Berry ſmall, ovate-globular, crowned with a ſhort five-toothed calyx, marked with ten longitudinal deep grooves, two-celled; coriaceous when ripe, dry, bipartile, of a light bay inclining to ſtraw colour. In each cell one ſeed, faſtened to the bottom of it, flattiſh on one ſide, wrinkled tranſverſely, and having a raiſed line along the middle; convex on the other ſide, with three larger dorſal grooves, and two ſmaller marginal ones, dark-coloured.

Gærtner attributes Browne's ſynonym to this ſpecies, which Swartz gives to his *citrifolia*.—Browne does not deſcribe any of his ſeven ſpecies of *Pſychotrophum*, except the laſt ſhortly; which is *P. herbacea*. He remarks in general, that they are all very common in Jamaica, in the woods, growing beſt in a rich ſhaded ſoil; that they are for the moſt part ſhrubby, and riſe from three to ſix or ſeven feet in height; that the leaves are oppoſite in all, and the foot-ſtalks are generally ſupported with ſtipules at their inſertions; that the flowers are commonly in looſe cluſters, terminating the ſtalks and branches; and that the ſeeds of all the ſpecies are pretty much like thoſe of Coffee.

The very numerous ſpecies of this genus, natives of the Weſt Indies, were unknown to Linnæus. The form of the corolla is different in the ſeveral ſpecies; tubular, ſalver-ſhaped or funnel-ſhaped; with the opening villoſe in ſome, naked in others. The inflorescence in almoſt all is raceme-paniculed. The berry is generally one-celled, though the unripe fruit appears to have two cells[a]. In Gærtner's ripe fruit however there are certainly two cells: and *Nonatella* of Aublet has a five-celled fruit, but only two ſeeds.

2. This reſembles the preceding ſo much, that it may be only a variety; the leaves however are perfectly ovate and ſhining; whereas in that they are lanceolate-ovate and dark green not ſhining.

Native of Jamaica on rocks in the interior of the iſland[b].

3. This differs from the other ſpecies in habit, and in having axillary flowers.—Native of Guiana, in woods[c].

4. This differs from *P. glabrata* (n. 2.) in having longer thickiſh leaves, larger flowers, and roundiſh berries.—Native of Jamaica and Hiſpaniola, in dry coppices[d].

5. Trunk ten or twelve feet high, with many branches at the top, and the bark reddiſh brown on the outſide and red within. Leaves ſubſeſſile, wide, acute, ſmooth, pale green underneath, with purple nerves. Stipules deciduous, long, acute, one on each ſide within the leaves. Flowers in terminating racemes. Corolla white. The bark dyes ſilk and cotton of a fine red.

Native of Guiana, in great foreſts, eſpecially in wet places, and called there *Simira*[e].

6. This differs from the reſt of the genus in its very remarkable ſhagginess, and extremely ſpreading habit.—Native of Jamaica, in the ſouthern parts, in old woods.

7. This differs from the preceding in its ſmoothneſs and in having the branches of the panicle reflex. A peculiar very fetid ſubacid odour proceeds from the branches when broken, and the leaves when bruiſed, like that of *Comocladia* and *Schradera capitata*.

Native of Jamaica, in the ſouthern parts, in mountain woods.

8. The leaves are very like thoſe of the Lemon in colour and conſiſtence. It is diſtinct from the reſt in leaves, ſtipules and berries[f]. The latter, as Gærtner remarks, are ſoft, one-celled and red, therefore very different from thoſe of the firſt ſpecies.—Native of the Weſt Indies.

9. This is a ſhrub, putting forth many ſtems from the root, which are ſtraight, branched, and eight feet high. Leaves wide, ovate, acute, ſmooth, quite entire, petioled. Stipules two, oppoſite, roundiſh, deciduous, one on each ſide; within the baſe of the petioles. Flowers panicled, terminating. Corolla white.

Native of Guiana, on the banks of the river Sinemari; flowering in ſeptember. The country name is *Maypouri-Crabri*; becauſe the *Maypouris* or wild kine feed on the leaves and branches[g].

10. This differs from the others in the leaves, which are obovate, acuminate, cartilaginous at the edge, and furniſhed with very minute briſtles, nerved and veined, dark green and ſhining above, beneath pale and ſomewhat glaucous, on roundiſh petioles. Swartz found it in woods, in the ſouthern parts of Jamaica, flowering in ſpring.

11. This is diſtinguiſhed by the leaves and ſtipules. The leaves are oblong, acuminate both ways, but blunt at the top, entire, nerved and veined, flat, thin and ſomewhat membranaceous, ſmooth, on round and thick petioles. Stipules ovate, wide, half-embracing, acuminate, bifid at the top, deciduous.—Native of Hiſpaniola in coppices.

12. It differs from the preceding in having a more ſpreading habit, the leaves more ovate and nerved, whence the ſurface is leſs ſmooth than in that; the margins alſo are ſlightly waved, and the ſtipules are larger[h]. The leaves, according to Willdenow, are not properly nerved, but have prominent veins.—Native of Jamaica, in coppices.

13. Swartz and Willdenow diſtinguiſh this both from the preceding and the firſt ſpecies with which Jacquin had confounded it. It is a ſubereCt branched ſhrub, the height of a man. The leaves are attenuated at the baſe, quite entire, ſhining, petioled, of various ſizes. Flowers inodorous, white: tube erect, ſomewhat funnel-ſhaped, three times as long as the border. Stamens often ſix with a ſix-cleft corolla, or ſeven with the corolla ſeven-cleft. Berries red, crowned with the calyx almoſt of the ſame colour, and containing a red pulp. Seeds white.

Native of Carthagena in New Spain, in coppices, among buſhes, and in hedges, very common; flowering there in auguſt[i].

14. This ſmall ſhrub ſeldom riſes above four or five feet in height, and is eaſily diſtinguiſhed by its tufted buſhy form and ſmooth leaves[k].

In habit it differs from the Pſychotriums. Browne, having ſeen only the unripe fruit, called it a two-celled drupe, and made a new genus of this ſhrub. The unripe berry is hard and two-celled; but when ripe it becomes juicy, and has a ſweet taſte; it has two ſeeds, but the partition diſappears.

Native of Jamaica, in the northern parts, in dry coppices, among Logwood. Browne ſays it is common about the ferry and in the Savanna near Hunt's bay.

15. Leaves on very ſhort petioles, from one to two inches in length, entire, ſmooth, paler and very mi-

nutely dotted underneath, ſcarcely nerved, veined, on very ſhort petioles. Stipules very ſmall; interpoſed between the leaves, entire, ſubciliate. Racemes two inches long, looſe, compound. Berry oblong, a little acuminate at both ends, ſmooth.—Native of Jamaica, in coppices on the mountains.

16. This is a running ſhrub, rooting in the trunks of old trees, and ſubparaſitical. Branches quadrangular towards the end, pendulous, ſmooth. Leaves an inch long, entire, veinleſs with ſcarcely apparent nerves, very ſmooth, bright green, pale underneath; on ſhort round petioles, flat above. Stipules or ſheaths ſmall, membranaceous, between the petioles, permanent. Racemes ſolitary, erect, the length of the leaves. Peduncles half an inch long, roundiſh, ſmooth, red: branchlets oppoſite, decuſſated, faſtigiate like a cyme, ſpreading, three-parted at the top; flowers pedicelled, white, ſmall. Berry globular or obovate, retuſe, crowned with the calyx, ſcarlet.

Native of the Weſt Indies. Found in the woods of Martinico, by Jacquin; in Paradiſe mountain, Monſerrat, where it is called *Climbing Vine*, by Ryan; in St. Chriſtopher's, by Fahlberg; in the mountains of Dominica and Guadeloupe, by Du Ponthieu.

17. This may be diſtinguiſhed from the reſt at firſt ſight by the diſpoſition of the branches, &c.—Native of Hiſpaniola, on open ſpots in a cretaceous ſoil, flowering in june.

18. Upright, branched. Branches numerous from the root. Leaves entire, veined, ſmooth, paler underneath, on ſhort petioles. Stipules ſhrivelling, deciduous, with two awl-ſhaped teeth. Racemes terminating, ſolitary: common peduncles long, round, ſmooth. Flowers ſmall, whitiſh. Berry roundiſh, ſcarlet, pendulous, the ſize of a red Currant. Seeds hemiſpherical, ſtriated. It flowers in june, and the berries are ripe in july.—Native of Hiſpaniola, on dry hills, in a cretaceous ſoil [k].

19. Native of the iſland of Otaheite [l].

20. This is a ſhrub from two to three feet in height, with round knobbed ſmooth branches. Leaves on ſhort petioles, acuminate, entire, nerved and veined. Flowers ſubſeſſile, with a three-leaved involucre, and linear ſpreading leaflets or bractes, the length of the pedicels. Berry roundiſh, with a very minute calyx at top, black, ten-grooved. Seeds hemiſpherical, grooved.—Native of Jamaica and Guiana [m].

21. This differs from the preceding in having ovate leaves, the flowers panicled, the ramifications divaricating and flexuoſe, and the peduncles naked not involucred. It reſembles *P. marginata*, but is ſufficiently diſtinct, in having the ſtipules two-toothed, the margin of the leaves naked, and the panicle flexuoſe.—Native of Cayenne, in barren places [l].

22. The trunk of this ſhrub is from two to three feet in height and branched. The branches are knobbed. Leaves ovate-oblong, acuminate, ſmooth, dark green above, paler underneath, petioled. Stipules embracing, four-lobed, annexed. Flowers in terminating racemes. Involucre of the calyx four-leaved; the leaflets long and narrow. Corolla white; with a ventricoſe tube, and a five-cleft border, with acute lobes. Berry black, ten-ſtreaked, five-celled.—Native of Guiana, in the woods of Orapu, flowering and fruiting in auguſt.

23. This alſo is a ſhrub with the trunk four or five feet in height, and branched at the top. Branches knobbed. Leaves wide, ovate-oblong, acute, ſmooth, quite entire, on ſhort petioles. Stipules deciduous, oppoſite, oblong, blunt, one on each ſide at the baſe of the petioles. Flowers in terminating racemes: raceme violet. Involucre of the calyx four-leaved; leaflets long, narrow, acute. Corolla white. Berry violet, ten-ſtreaked, five-celled.—Native of Guiana, in woods, flowering in july [n].

24. This ſhrub is a fathom in height, with upright, four-cornered, even branches. Leaves oblong, acuminate at both ends, entire, nerved and veined, ſmooth, ſomewhat wrinkled, paler underneath, on round petioles, which together with the nerves are pubeſcent underneath. Stipules interpoſed between the leaves, wide, ſmooth. Raceme almoſt upright: common peduncle round flatted a little, elongated, pubeſcent; branches ſpreading horizontally, three-parted at the top; pedicels very ſhort. Flowers ſeſſile, three or four, aggregate, pale. Bractes wide, concave, ſharp, at the baſe of the branchlets of the raceme, and of the pedicels, and under the flowers, pubeſcent. Berry oblong, crowned, two-grooved, very dark blue. Seeds grooved. It flowers in may and june.

Native of Jamaica, on high mountains in the ſouthern parts.

25. This is ſuffruticoſe, and from twelve to ſixteen feet in height. Stem upright, ſubherbaceous, thick, ſtiff, grooved, ſmooth; with herbaceous, ſtiff, angular, ſmooth branches, and axillary, grooved branchlets. Leaves a foot and more in length, and three inches wide, with a ſhort point, quite entire, nerved and veined, ſmooth, paler underneath; on ſhort, thick, roundiſh, ſmooth petioles. Stipules interpoſed between the leaves, wide, awl-ſhaped at the tip, ſmooth. Panicles large, at the ends of the branchlets. Common peduncle ſometimes longer than the leaves, roundiſh, upright, ſtriated: branches in threes and fours, in a ſort of whorl, ſtiff, ſomewhat compreſſed, margined, thicker towards the baſe, ſtriated, three or four-parted, again ſubdivided at the tip: flowers numerous, on ſhort pedicels, ſomewhat cluſtered, pale. Berry ovate, crowned with a very minute calyx. Seeds plano-convex. It flowers in april; and differs in habit, leaves, ſtipules, &c.

Native of Jamaica, in the interior weſtern parts, in mountain coppices.

26. This is a ſingular ſpecies, with the branches of the panicle divaricating and directed all one way, as in the *flexuoſa*, *n.* 21. which it very much reſembles in habit.—Native of Jamaica, on the Blue Mountains.

27. Roots long, creeping. Stem two or three feet high, herbaceous only a little ſhrubby towards the bottom, thick, round, at the top leafy and ſmooth, ſomewhat ſucculent. Leaves a foot long, acuminate, entire, with arched nerves, ſhining, pale underneath. Petioles long, round, thick. Peduncles the length of the petioles, round, ſmooth, three-parted at the top; branchlets ſhorter than the peduncle, many-flowered at the top: flowers ſubſeſſile, cluſtered, ſmall, pale red. Bractes acute, oppoſite, convex, at the ſubdiviſions of the peduncles. Berry ſpherical, ſcarlet, when dry compreſſed. Seeds plano-convex, compreſſed, creſted on the outer ſide. It flowers in ſpring.—Native of Jamaica, in low wet places on mountains [o].

28. This very much reſembles the next ſpecies, but yet it is diſtinct. Stems creeping, from two feet to a fathom in length, with the branches erect, alternate, round, jointed, perennial. Leaves petioled, acute at both ends, and even on both ſides. Stipules roundiſh, deciduous. Corymbs terminating, brachiate, ſcarcely longer than the leaves. Seeds two-grooved in the outer convex ſide.—Native of the Eaſt Indies [p].

29. Stem filiform, round, ſmooth. Leaves ſpreading, acute, bluntly ſerrate, ſmooth above and ſhining, below ſilvery and white. Petioles round, longiſh, erect, pubeſcent. Stipules oppoſite, ovate, emarginate, white. Peduncles ſhorter than the petioles, erect, thickiſh, round, commonly radical but ſometimes axillary, few-flowered. Flowers white. Berry roundiſh, ſcarlet, crowned. Seeds hemiſpherical, oblong, grooved.

Native of the Weſt Indies, in ſhady places [r]. In Jamaica. Jacquin found it in Martinico, bearing flowers and ripe fruits in december. Alſo in the Eaſt Indies.

30. Root perpendicular, roundiſh, ſomewhat branched. Leaves approximating, ſpreading very much, quite entire, acuminate, having a round prominent rib underneath, but ſharpiſh above, even, flat, from two to three inches in length. Stipule ſingle on each ſide, ſtiffiſh, horizontal, very ſhort, deciduous. Flowers white, ſmall, ſeſſile, on ſhort, ſolitary peduncles, the

[k] Swartz, [l] Forſter. [m] Swartz. [n] Willdenow. [o] Aublet.

[p] Swartz. [q] Linn. mant. [r] Swartz.

length of the petioles, from two to five together. Each flower has a ſimple braćte ſo ſmall as to be ſcarcely viſible. Perianth ſmall, five-toothed, permanent, with very ſmall teeth, ſomewhat rolled back. Corolla one-petalled, funnel-form: tube longer than the calyx, cylindrical, widening upwards: opening almoſt cloſed with ſoft villoſe hairs: border five-parted; with the ſegments lanceolate acute pubeſcent within, ſomewhat revolute, almoſt equal to the tube. Nectary a thickiſh rim, obſcurely five-cornered, whitiſh, ſurrounding the baſe of the ſtyle. Filaments very ſhort inſerted into the throat of the corolla. Anthers ſmall, linear, ereć, pubeſcent at the top. Germ inferior, roundiſh. Styles almoſt cylindrical, ereć, the length of the tube. Stigma thickiſh, two-parted. Berry ſubovate, even, crowned with the calyx, one-celled. Seeds two, united, oblong, acute at both ends, flat within, gibbous on the outſide [s].

Native of North America, in the warmeſt part of it.

This plant is ſuppoſed to be the Ipecacuanha, but on an authority which ought not to be followed implicitly, namely that of an American quack, who ſent a ſpecimen of it in flower to the Spaniſh governor, who communicated it to Mutis.

Dr. Woodville has given a figure of the true plant from a ſpecimen preſerved in ſpirits, and ſent from Brazil by Governor Phillip to Sir Joſeph Banks; but it has not the fructification.

There are three ſorts of Ipecacuanha root in our ſhops—the aſh-coloured or gray, the brown, and the white. The aſh-coloured is brought from Peru, and is a ſmall wrinkled root, bent into a great variety of figures, brought over in ſhort pieces, full of wrinkles and deep circular fiſſures, down to a ſmall white woody fibre that runs in the middle of each piece: the cortical part is compaćt, brittle, and looks ſmooth and reſinous on breaking: it has very little ſmell; the taſte is bitteriſh and ſubacrid, covering the tongue as it were with a kind of mucilage. The brown is ſmall, ſomewhat more wrinkled than the foregoing; of a brown or blackiſh colour without, and white within; this was brought from Brazil. The white ſort is woody, has no wrinkles, and no perceptible bitterneſs. The firſt is that uſually preferred for medicinal uſe. The brown, even in a ſmall doſe, has been ſometimes obſerved to produce violent effects. The white, though taken in a large one, has ſcarcely any effect at all; Dr. Irving has aſcertained by experiments, that this root contains a gummy and reſinous matter, and that the gum is in much greater proportion, and is more powerfully emetic than the reſin; that the cortical is more active than the woody part, and that the whole root manifeſts an antiſeptic and aſtringent quality. He alſo found its emetic property to be moſt effectually counteraćted by means of the acetous acid, inſomuch that thirty grains of the powder taken in two ounces of vinegar, produced only ſome looſe ſtools.

The firſt account we have of Ipecacuanha is that publiſhed by Piſo in 1649; but it did not come into general uſe till thirty years after, when Helvetius, under the patronage of Lewis XIV. employed it at the Hotel de Dieu, and introduced this root into common praćtice: experience has proved it to be the mildeſt and ſafeſt emetic with which we are acquainted, having this peculiar advantage, that if it does not operate by vomit, it readily paſſes off by the other emunctories.

It was firſt introduced with the character of an almoſt infallible remedy in dyſenteries and other inveterate fluxes, and alſo in diſorders proceeding from obſtructions of long ſtanding: nor has it loſt much of its reputation by time. In the ſpaſmodic aſthma, Dr. Akenſide remarks, that where nothing contraindicates repeated vomiting, he knows no medicine ſo effectual. In violent paroxyſms a ſcruple procures immediate relief: where the complaint is habitual, from three to five grains every other morning may be given for a month or ſix weeks.

This medicine has alſo been ſucceſsfully uſed in hemorrhages. Several caſes of menorrhagia are mentioned by Dahlberg, in which one-third or half a grain was given every four hours till it effected a cure. Theſe ſmall doſes are likewiſe found of great uſe in catarrhal and even conſumptive caſes, as well as in various ſtates of fever. Dr. Cullen informs us, that he knew a praćtitioner who cured intermittents by giving five grains of Ipecacuanha, or enough to excite nauſea, an hour before the acceſſion of the fit was expected; and that Dr. Thompſon, formerly of Montroſe, propoſed to cure agues by emetics given at the time of acceſſion, or at the end of the cold ſtage; this praćtice has alſo been ſucceſsful, and may indeed be executed by tartar emetic; but Ipecacuanha is more manageable, and generally more eaſy to the patient.

This root, particularly in the ſtate of powder, is now advantageouſly employed in almoſt every diſeaſe in which vomiting is indicated; and when combined with Opium, under the form of *pulvis ſudorificus*, it furniſhes us with the moſt uſeful and active ſweating medicine which we poſſeſs. It is alſo given with advantage in very ſmall doſes, even when it produces no ſenſible operation. The full doſe in ſubſtance is a ſcruple, though leſs doſes will frequently produce an equal effect. The officinal preparation is *Vinum Ipecacuanhæ* [t].

31. This is a ſhrub, a fathom in height; the branches and branchlets ſubdivided, upright, round, ſhining; the latter dark red. Leaves entire, nerved and veined, very ſmooth, ſhining; on ſhort, round, ſmooth petioles. Stipules ſmall, interpoſed between the leaves, with the teeth lanceolate. Flowers not in a true corymb, but in a panicle approaching nearer to that form than in any of the reſt, eſpecially when nodding with a load of berries: branchlets trichotomous, ereć, faſtigiate: common peduncles ſhorter than the leaves, round, ſmooth, purple: braćtes awl-ſhaped, coloured, at the ſubdiviſions of the panicle. Flowers purple. Berry roundiſh, twin, compreſſed a little, dark red. Seeds hemiſpherical, ſtriated. It flowers in ſummer.—Native of Jamaica, in the high mountains.

32. This alſo is a ſhrub, a fathom high, with the branches ſubdivided, round, ereć, pubeſcent. Leaves entire, nerved, pubeſcent eſpecially underneath, ſometimes ſubtomentoſe, ſoftiſh, from two to three inches long, on roundiſh petioles of a middling length. Stipules interpoſed between the leaves, with awl-ſhaped ſhort teeth. Panicles terminating, ereć, the length of the leaves, with ſpreading ſubfaſtigiate branchlets, almoſt forming a cyme, trichotomous, with a floret in the middle commonly ſeſſile. Common peduncles an inch long, round, pubeſcent. Braćtes linear, oppoſite at the ſubdiviſions of the panicle. Flowers yelloviſh green. Berry roundiſh-twin, crowned, pubeſcent, black with a blue juice. Seeds hemiſpherical, grooved and ſtriated. It flowers the whole year.—Common in Jamaica and other iſlands of the Weſt Indies.

33. This differs from all the others in its ſubcymoſe inflorescence, and in having the common peduncles elongated.—Native of Jamaica, in the interior, in mountain woods.

34. This is diſtinguiſhed by the leaves being very much veined, and the panicles ſaffron-coloured [u].

The leaves are not nerved, but veined, with the veins prominent: ſuch leaves ſhould rather be called ribbed, a nerved leaf being that which has ſeveral undivided nerves ſpringing from the baſe [v].

Native of the Weſt Indies, in mountain coppices.

35. This is a ſhrub from five to ten feet high, with the branches thick, four-cornered, ſmooth, almoſt ſimple. Leaves acuminate at both ends, ſubciliate, membranaceous, ſomewhat rigid, many-nerved, ſmooth on both ſides; on round, pubeſcent petioles. Stipules interpoſed between the leaves, connate, membranaceous, truncated in the middle, having on each ſide a long linear ereć ſubciliate toothlet. Panicle often ſhorter than the leaves: common peduncle an inch long, flatted or angular, ſmooth, ſometimes red:

[s] Mutis in Linn. ſuppl.

[t] Woodville. [u] Swartz. [v] Willdenow.

branches

branches decuſſated, from upright ſpreading, ſimply ſubdivided; with the pedicels ſcattered, red, longer. Berry roundiſh, larger, two-grooved, crowned. Seeds hemiſpherical, grooved. It flowers in ſpring and ſummer.

Native of Jamaica, on the Blue Mountains. It reſembles Chiococca paniculata of the younger Linnæus's Supplement ſo much, that it can ſcarcely be different: or if that is to be diſtinguiſhed, ſtill it muſt be a ſpecies of Pſychotria[b]. See the next ſpecies.

36. This is a high tree, with very ſmooth round branches. Leaves on ſhort petioles, acuminate at both ends, quite entire, veined. A thin membrane combines the leaves, and is extended within them into two ſtipular teeth. Panicle terminating branched. Flowers yellow. Berry yellow, compreſſed; having a lateral groove, it appears as if it were twin. It is perhaps different from the ſpecies immediately foregoing, this being arboreous, that ſhrubby; the leaves being ovate in this, lanceolate-ovate in that. The deſcription we have of it is too ſhort to ſtate other differences.

Found at Surinam by Dalberg, and in South America by Mutis[a].

37. This is a ſhrub with round ſmooth branches and coloured branchlets. Leaves decuſſated, entire, nerved and veined, ſmooth, five or ſix inches in length; on quadrangular ſmooth petioles, half an inch long. The two lobes of the ſtipules are ovate, obtuſe, preſſed cloſe, large, permanent, rigid. Panicle almoſt the length of the leaves: common peduncle two inches long, four-cornered, blood-red; branchlets erect, compreſſed, grooved, ſhort, trichotomous, coloured; flowers pedicelled, erect. Pericarp, when unripe, two-celled, with one ſeed in each cell, crowned with the calyx. Certainly not to be ſeparated from the Pſychotriums, and reſembling *P. crocea* and *alpina* very much in many reſpects.—Native of the Weſt Indies and Guiana[y].

38. The trunk of this is a foot high or more, with many knobbed branches at the top. Leaves ovate, acute, ſmooth, quite entire, petioled. Stipules embracing, two-lobed, annexed; the lobes oblong, oppoſite. Flowers in terminating racemes. Calyx naked. Corolla yellow, with a very long tube, and a five-cleft border; the clefts long and acute. Berry five-celled.

Native of Guiana, near mount Courou; flowering in ſeptember.

39. This is a perennial plant, four feet high, with a knobbed, branched ſtem. Leaves ovate-oblong, acute, ſmooth, quite entire, petioled, annexed to an embracing, four-toothed ſheath. Flowers terminating, in panicles. Calyx knobbed. Corolla white. Berry violet.

Native of Cayenne and Guiana, in barren places; flowering and fruiting in auguſt[y].

PSYCHOTROPHUM. See *Pſychotria*.]

PSYLLIUM. See *Plantago*.

PTARMICA. See *Achillea*, [*Parthenium*, *Xeranthemum*.]

PTELEA. (Πτελεα of *Theophraſtus and Dioſcorides: the name of a tree uſed in building.*)

Lin. gen. n. 152. *Reich. n.* 159. *Schreb. n.* 1505. *Gærtn. t.* 49. *Juſſ.* 375.

Claſſ. 4. 1. Tetrandria Monogynia. *or* Dioecia Tetrandria.

Nat. order of *Terebintaceæ*, Juſſ.

GENERIC CHARACTER.

* *Male.*

CAL. *Perianth* four-parted, acute, ſmall, deciduous.

COR. *Petals* four, oblong, concave, ſpreading, larger than the calyx, coriaceous.

STAM. *Filaments* four, awl-ſhaped, erect, curved in at the top, flattiſh and villoſe at the baſe, almoſt the length of the corolla. *Anthers* roundiſh.

PIST. *Germ* ovate, ſmall, abortive. *Style* very ſhort, bifid at the top. *Stigmas* obſolete.

* *Female.*

CAL. and COR. as in the Male.

STAM. *Filaments* as in the Male, much ſhorter than the corolla. *Anthers* roundiſh, barren.

PIST. *Germ* ovate, compreſſed, biggiſh. *Style* ſhort, compreſſed. *Stigmas* two, bluntiſh, diverging.

PER. *Drupe* roundiſh, large, juiceleſs, compreſſed, membranaceous-winged, two-celled.

SEEDS ſolitary, oblong, attenuated upwards.

OBS. *Some of the flowers have a five-cleft calyx, and a five-petalled corolla. In thoſe, and even in the flowers that are four-cleft, there are often five, ſix and ſeven ſtamens. In each cell of the germ there are two ſeeds, but only one of them, and ſometimes only a ſingle ſeed in the whole drupe comes to perfection. In the female flowers the anthers are ſometimes polliniferous, and hence this genus might be referred to the claſs Polygamia. Willdenow has continued it in the genus Tetrandria, wherein Linnæus had placed it.*

ESSENTIAL CHARACTER.

Cal. four-parted, inferior. *Cor.* four-petalled. *Stigmas* two. *Fruit* with a roundiſh membrane, having one ſeed in the middle.

β. Ptelea pentaphylla. *Five-leaved Ptelea.*

Munchh. Hauſvat. 3. 242. *Fabric. helmſt.* 416. *Du Roi harbecc.* 2. 203.

DESCRIPTION, *&c.*

The three-leaved Ptelea grows naturally in North America; it was firſt diſcovered in Virginia by Mr. Baniſter, who ſent the ſeeds to England, from which ſome plants were raiſed at Fulham, and ſome other curious gardens; but being planted in the open air, they were deſtroyed by a ſevere winter, ſo that there were ſcarce any of the plants left in England. In 1724, Mr. Cateſby ſent over a good quantity of the ſeeds from Carolina, which ſucceeded ſo well as to furniſh many gardens with the plants. This riſes with an upright woody ſtem ten or twelve feet high, dividing upwards into many branches, covered with a ſmooth grayiſh bark, garniſhed with trifoliate leaves ſtanding upon long foot-ſtalks. The leaflets are ovate or ovate-lanceolate, ſmooth, and of a bright green on their upper ſide, but pale on their under; theſe come out late in the ſpring, ſoon after which the bunches of flower-buds appear, which is generally in the beginning of june, the leaves being then but ſmall, and afterwards increaſe in ſize, but are not fully grown till the flowers decay. The flowers are produced in large bunches at the end of the branches; they are of an herbaceous white colour, compoſed of four or five ſhort petals, ending in acute points; theſe are faſtened at their baſe to a ſhort calyx, cut into four ſegments almoſt to the bottom. In the center is ſituated an orbicular compreſſed germ ſupporting a ſhort ſtyle, which is attended by four awl-ſhaped ſtamina; the germ afterwards turns to a capſule ſurrounded by a leafy border, having two cells, each containing one ſeed.

[Medicus firſt obſerved that the Ptelea was dioecous. According to Willdenow, it is a polygamous ſhrub.]

PROPAGATION AND CULTURE.

This ſhrub may be propagated by cuttings planted in pots of freſh rich earth, and plunged into a moderate hot-bed. The beſt time for this is in the beginning of march, but they muſt be carefully managed ſo as not to have too much heat, and ſhaded from the ſun in the middle of the day, otherwiſe they will not ſucceed. It may alſo be propagated by layers, but theſe are often two years before they take root; if good ſeeds can be procured either here or from abroad, the plants raiſed from thoſe will be much ſtronger.

Theſe ſeeds may be ſown in the beginning of april, on a bed of light earth, in a warm ſheltered ſituation,

[b] Swartz. [a] Linn. ſuppl. and Willdenow.
[y] Swartz. [y] Aublet.

where, if the ground is moiſtened in dry weather, the plants will come up in ſix weeks; but if the ſeeds are ſown in pots, and placed on a very moderate hot-bed, the plants will come up ſooner, and make greater progreſs the firſt year; but they muſt not be forced or drawn, for that will make them very tender; therefore in june the plants ſhould be expoſed to the open air, in a ſheltered ſituation, where they may remain till the froſt comes on, when thoſe in the pots ſhould be either placed under a common frame, to ſhelter them from ſevere froſt, or the pots plunged into the ground, near a hedge, that the froſt may be prevented from penetrating through the ſides of the pots to the roots of the plants. The following ſpring the plants may be planted into a nurſery-bed, at about one foot diſtance, where they may grow two years, by which time they will be fit to tranſplant where they are deſigned to remain.

Theſe plants are a little tender while they are young, therefore will require ſome protection the firſt and ſecond year, but particularly from the early froſts in autumn, which frequently kills the tops of the tender ſhoots before they are hardened; and the more vigorous the plants have grown the preceding ſummer, the greater danger there is of their being killed, therefore they ſhould be ſcreened either with mats or ſome other covering; but as they advance in ſtrength, they become more hardy, and are rarely injured by froſt.

[PTELEA VISCOSA. See *Dodonæa*.

PTERANTHUS. See *Camphoroſma*.

Lin. ſpec. 1533. *Reich.* 4. 397. *Brown. jam.* 91. *n.* 8. *Plum. amer.* 21. *t.* 30. *fil. t.* 51. *Pet. fil.* 131. *t.* 3. *f.* 10. (Lonchitis).
Fronds decompound, leaflets pinnate, the loweſt ſemipinnatifid, the terminating ones and thoſe of the baſe very long.

22. Pteris atropurpurea.
Lin. ſpec. 1534. *Reich.* 4. 397. *Gron. virg.* 197.
Fronds decompound pinnate, pinnas lanceolate, the terminating ones longer.

23. Pteris nigra.
Retz. obſ. 6. 38. *n.* 85.
Frond tripinnate, leaflets ovate, the terminating one ſubtrilobate.

24. Pteris arguta.
Vahl ſymb. 1. 84.
P. ſerrulata. *Forſk. deſcr.* 187.
Filix non ramoſa jamaicenſis pediculo albicante, &c. *Pluk. phyt. t.* 290. *f.* 2.
Fronds ſubbipinnate, lower leaflets twice two-parted, pinnas lanceolate ſerrate.

25. Pteris biaurita.
Lin. ſpec. 1534. *Reich.* 4. 397. *Lour. cochinch.* 679. 835. *Brown. jam.* 90. *n.* 4. *Plum. amer.* 10. *t.* 14. *fil. t.* 15. *Pluk. phyt. t.* 401. *f.* 1. *Pet. fil.* 134. *t.* 3. *f.* 11. (Filix).
Fronds pinnate, pinnas pinnatifid, the loweſt two-parted.

26. Pteris quadriaurita.
Retz. obſ. 6. 38. *n.* 86.
Fronds pinnate, pinnas pinnatifid toothed at the top, the four lower pairs bifid.

27. Pteris ſemipinnata.
Lin. ſpec. 1534. *Reich.* 4. 397. *Oſb. it. t.* 3. *f.* 1. *Thunb. jap.* 333.
Fronds ſubbipinnate, the lateral leaflets and the loweſt lobe ſemipinnatifid.

28. Pteris ſerrulata.
Lin. ſyſt. 931. *ſuppl.* 445.
Fronds ſemibipinnate linear ſerrulate.

29. Pteris heterophylla.
Lin. ſpec. 1534. *Swartz obſ.* 397. *Brown. jam.* 91. *n.* 5.
Adiantum hexagonum. *Lin. ſyſt.* 940. 25. *Plum. fil.* 84. *t.* 37.
Ruta muraria major, fol. variis, &c. *Sloan. jam.* 1. 92. *t.* 53. *f.* 2.
Fronds bipinnate, pinnas ovate-oblong ſerrate blunt, the ſertile ones quite entire.

---

30. Pteris lunulata.
Retz. obſ. 2. 28. *n.* 99. *t.* 4.
Frond pinnate, pinnules alternate petioled creſcent-ſhaped ſtriated.

31. Pteris eſculenta.
Forſk. prodr. n. 418. *eſcul.* 47.
Fronds ſuperdecompound grooved, leaflets pinnate, pinnas linear decurrent, the uppermoſt ſhorter.

32. Pteris comans.
Forſk. prodr. n. 419.
Fronds pinnate, leaflets pinnatifid, pinnas elongated lanceolate, at the top attenuated ſerrate.

33. Pteris rotundifolia.
Forſk. prodr. n. 420.
Fronds pinnate hiſpid, pinnas ſuboppoſite roundiſh obſoletely crenate.

34. Pteris humilis.
Forſk. prodr. n. 421.
Fronds ſubbipinnate, leaflets oblong gaſhed ſubpinnate, the outmoſt obſoletely crenate confluent.

DESCRIPTIONS, *&c.*

1. Root filiform, long, creeping, tomentoſe, brown. Shoots alſo creeping, filiform, long and hiſpid. Fronds ſome barren, others fertile; the former obovate or ſomewhat oblong, ſmooth, quite entire, blunt, petioled; the latter double the length, lanceolate, blunt, fruiting very cloſely underneath along the wide margin. Native of the Eaſt Indies, Japan, and Cochinchina, on rocks and trees [a].

2. Fronds cordate almoſt quite entire, ſtriated, erect [b].—Native of Domingo, of Algiers, according to Deſfontaines, and according to Loureiro, of Cochinchina.

3. Native of the Weſt Indies [c].

4. Native of Domingo.

5, 6. Natives of the Weſt Indies.

7. Native of the Weſt Indies [d]; according to Linneus: but this is a miſtake, for it is a native of the Eaſt Indies, and the ſame with Marſilea minuta of Linneus's Mantiſſa.

8. It is not known of what country this is a native.

9. Native of Dominica and Martinico in bogs [e]. If it be the ſixth Acroſticum of Browne, it alſo grows in the cooler mountains of Jamaica, and ſeldom riſes above three feet and a half from the ground.

10. Stipe angular, grooved, ſmooth. Frond wholly ſmooth, a foot and half high with the ſtipe. The lower pinnas are in pairs, the reſt are ſimple, attenuated at bottom, a finger's length.—Native of Japan [f].

11. This plant ſeldom riſes above fourteen or ſixteen inches; it is remarkable for its narrow ſimple leaves and undivided ſtalk.—Native of Jamaica and Dominica, in cool moiſt places, and in woods near rivulets [g].

12. Native of Hiſpaniola [h].

13. Root creeping long fibrous black. Fronds five feet long, erect, on round ſmooth grooved long ſtipes. Pinnas linear-lanceolate with a long point, ſmooth, ſtriated tranſverſely, pale green, flat, on ſhort petiols, ſometimes very minutely ſerrate [i].

Browne ſays, it ſprings from a large firm root, and riſes commonly to the height of twelve or ſixteen inches, ſometimes more.

Native of China, Cochinchina and Jamaica.

14. Native of South America.

15. Leaves ſimple, milky white underneath, with a brown down at the margin: the ſtalk is pretty ſlender, and ſeldom ſhoots more than ten or twelve inches above the root [k].

Native of rocks in Dominica, and Jamaica, where Browne ſays it is common in the middle mountains of Liguanee.

16. Pinnas lanceolate or enſiform, narrowed at the baſe; the upper ones connate-ſubdecurrent, the loweſt petioled and often bifid or trifid [l].

Native of the iſlands of Candia and Elba. Vahl gathered it about Naples, Forſkahl in Arabia, and Thunberg at Nagaſaki in Japan.

17. This little plant ſeldom riſes above four or ſix inches from the ground; it is beautifully diſſected, and of a very ſingular form, but varies much in its diviſion and appearance [m].—Native of Jamaica, Dominica and the Society Iſles; Linneus adds Siberia,

[a] Linn. ſpec. Thunb. Lour. [b] Loureiro. [c] Swartz.
[d] Linn. [e] Idem. [f] Thunberg. [g] Browne.
[h] Swartz. [i] Loureiro. [k] Browne. [l] Linn. mant.
[m] Browne.

noticing

noticing that the Siberian plant is smaller and snow-white underneath, with a ferruginous margin: but Swartz affirms that this is certainly different.

18. Frond weak, erect, a foot and half long: pinnas alternate, spreading, scarcely a finger's length; segments subopposite, entire, waved, nerved, smooth; sinuses rounded not acute.—Native of Japan, about Jedo [a].

19. This is our common Fern or Brake, called Braken in the north. The roots are creeping, and when cut obliquely present a kind of representation of the imperial eagle; whence Linnæus's trivial name of *aquilina*. Stem upright, eighteen inches, and in woods three or four feet high, angular, smooth, branched, rigid; all the pinnas sessile, hard, striated, bright green above, glaucous underneath [b]. The fructifications are in rough, tomentose, rufescent parallel lines along the margins of the pinnules, which are rolled back very much so as almost to cover the capsules when ripe [c].

Native of most parts of Europe on heaths and in woods.

A tolerably pure alkali is obtained from the ashes. The common people in many parts of England mix these ashes with water and form them into balls; these balls are afterwards made hot in the fire, and then used to make lye for scouring linen. Fern makes a very durable thatch, and is an excellent litter for horses and cows. Where fuel is scarce, they use it to heat ovens, and to burn limestone; for it affords a very violent heat. In the more inhospitable climates bread is made of the roots [d].

Thunberg informs us, that in Japan the young fronds, before the leaves are displayed, are eaten, and that bundles of them are exposed to sale in the shops during the months of april and may. The woody root is bruised, soaked in water, and boiled; and though quite black, it is eaten by the poorer sort.—Fern it is said may be destroyed by repeated mowings in summer, but the most effectual way is by paring and burning.

20. Native of Jamaica and Dominica. Browne says, it is very common in the mountains of the former, in the most open spots, and that it thrives best in a stiff clay.

21. The lower lateral leaves are longer at the base, pinnate only on the lower side.

Native of the same islands [e], and growing like the preceding, but never rising so high: it loves an open gravelly soil, and is very common on the lower hills of Jamaica [f].

22. Stipe a span high, dark purple, shining. Pinnas rolled back with a wide margin, on longer petioles the lower they are; the lowest petioles augmented with one or two pairs of smaller sessile pinnas.—Native of Virginia [g].

23. Stipe a span high, striated, channelled on one side, smooth and even, black. Branches of the frond opposite and alternate. Pinnules small, ovate, blunt, entire except the end one, which is commonly three-lobed. Fructification marginal, but often filling up the disk so completely, that the nerve of the pinnule only appears.—Native of China near Canton [h].

24. Stipe two feet high, very smooth and even. Frond pinnate: leaflets pinnatifid; the two lowest augmented with two leaflets on the lower side, and hence half bipinnatifid: pinnas smooth, the barren ones serrate to the base, the fruiting only at the tip. It can scarcely be distinguished from the next species, and may perhaps be only a variety of it: the pinnas are smaller, and the last is not elongated so much as in Plumier's figure of the *biaurita*.—Native of Arabia; sent also from Madeira [i].

25. A foot and half high, erect. Pinnas smooth, with linear blunt segments; the lowest divided into two shorter earlets. Fructifications linear [k].

According to Browne, it rises commonly to the height of two feet and a half or better, and is easily distinguished by the regular division of its lower ribs. Native of the West Indies and Cochinchina [l].

26. Stipe four-cornered, even. Pinnas pinnatifid almost to the nerve; segments blunt; the end one lanceolate, acuminate, long, serrate especially towards the tip. It is very distinct from the *biaurita* in size, in the serratures and number of the bifid pinnæ.—Koenig sent it from Ceylon [m].

27. Scape even. Fronds lanceolate, pinnate. Leaflets opposite, remote, pinnatifid: with the terminating apexes elongated: the lower margin of the leaves, and only that, is commonly pinnatifid, but not the upper; hence the leaflets are, as it were, semipinnate: the lowest segment also of the pinnas is longer than the rest, and in like manner semipinnatifid; all the rest being entire and blunt.—Found in China, by Osbeck [n], and in Japan by Thunberg.

28. Stipe half round, a span high, even, green, purple at bottom. Leaflets decurrent, opposite; the lowest unequally five-parted, with cuneiform pinnas, one or two of them elongated; the next similar, decurrent, but three-parted; those of the third or fourth pair simple and a little smaller; the last leaflet an inequal pinna, longer, united to the rest: the barren pinnas very finely serrate, the fertile ones scarcely crenate.—Native of Jamaica [o].

29. This is a very elegant little species, and rises to the height of sixteen or eighteen inches. It is pretty much divided, and the leaves when young are serrate; but as it begins to feed the margin reflects, and none of these are seen.

Native of Jamaica in moist and shady places: common about the cascade in St. Ann's [p].

It has been confounded with *Osmunda crispa* by Linnæus, but ought to be restored to this genus. The fructifications at first are in an interrupted line about the edge; whence *Adiantum hexagonum* of Linnæus is only a synonym of this; but when they are matured they become confluent, and are covered by the reflex margin [q], as Browne remarked.

30. Frond quite simple, a foot long and more. Stipe like ebony, shining, compressed. Pinnas green, even, striated, with the streaks radiating from the petiole to the margin. The outer margin fruiting, almost semicircular; the inner barren, scarcely curved. The upper pinnas are hatchet-shaped, and the terminating one three-cornered. The form of this agrees exactly with *Adiantum lunulatum* of Burman, ind. 235. except the five-flowered margin: but sometimes the margin is cleft into three or more segments; and thus a genuine species of *Pteris* resembles an *Adiantum*. This beautiful Fern was sent to Retzius from Bengal [r].

31. Fronds triply-pinnate, very large, radical, smooth, with the stipe grooved above, all the divisions alternate, except the more universal ones, which are sometimes opposite. Leaflets about two inches long, with the pinnas quite entire, blunt, rolled back at the edge, coriaceous, approximating, the lower ones separate, toothed here and there, or pinnatifid, the outmost gradually shorter. The marginal lines of fructification occupy almost the whole disk, with a thin little membrane, scarcely covering the seeds.

Native of the Society Isles in woods. The roots are eaten there by the poorer sort and when better food is scarce, though they are woody, insipid, and have little nourishment in them. In Otaheite this fern is called *e-Narré*.

32, 33, 34. Natives of New Zealand [s].

PTEROCARPUS. (*From πτερον a wing, and καρπος a fruit; having a winged fruit.*)

Lin. gen. n. 854. *Reich. n.* 925. *Schreb. n.* 1159. *Jacqu. amer.* 283. *Gærtn. t.* 156. *Juss.* 364. *Auctore Loeflingio.*

Class. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminosæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular-bell-shaped, five-toothed: *teeth* acute.

[a] Thunberg. [b] Pollich. [c] Weis. [d] Withering. [e] Linn. [f] Browne. [g] Linn. [h] Linn. [i] Retz. [k] Vahl. [l] Loureiro. [m] Retz. [n] Linn. [o] Linn. suppl. [p] Browne. [q] Swartz. [r] Retzius. [s] Forster.

COR. papilionaceous. *Standard* with an oblong claw, roundiſh-cordate, ſpreading, convex. *Wings* lanceolate, ſhorter than the ſtandard. *Keel* ſhort.

STAM. *Filaments* ten, united. *Authers* roundiſh.

PIST. *Germ* pedicelled, oblong, compreſſed. *Style* awl-ſhaped. *Stigma* ſimple.

PER. *Legume* roundiſh-ſickle-ſhaped, leafy-compreſſed, varicoſe with veiny ſides, woody within, not opening: the cells longitudinal.

SEED ſolitary, kidney-ſhaped, thicker at the baſe, appendicled at the top.

ESSENTIAL CHARACTER.

Cal. five-toothed. *Caps.* ſickle-ſhaped, leafy, varicoſe. *Seeds* few, ſolitary.

DESCRIPTIONS, *&c.*

1. This is a tree thirty feet high; the wood white and ſolid, without any reſin; the bark thick, outwardly of a ferruginous gray colour, inwardly ſubferruginous and ſmoothiſh; being cut tranſverſely when freſh, it betrays no marks of redneſs at firſt, but in a ſhort time it is variegated with many blood-red dots, that collect into little globules or tears. The tree itſelf, cut in different parts, in a ſhort time is full of the ſame bloody drops, ſhining and very clear; in the ſpace of ſome minutes, eſpecially if the ſun ſhines hot, they harden, and then are collected, under the name of *Sanguis draconis* or Dragon's blood. The bark wood and leaves have an aſtringent taſte. The long branches are adorned their whole length with alternate ſhining pinnate leaves, on a rib ſeven inches long, grooved above; they have five leaflets on each ſide with an odd one; theſe are lanceolate-oblong, bluntiſh, quite entire, veined, bright green above, pale green beneath, alternate, the outer ones an inch and half long, the middle ones two inches; on round ſhort ſubvilloſe petioles. The bark of the trunk and branches of the root, cut into pieces, is every where uſed by the inhabitants for cleaning their teeth. The reſin was formerly ſent from Carthagena into Spain, but ſince it has fallen into diſuſe in Europe for ſtopping blood, &c. the gathering of it is neglected[c].

[c] Jacquin.

Native of the Weſt Indies; alſo of the Eaſt Indies, unleſs that be a different ſpecies.

2. This is a ſtiffiſh ſhrub, with ſtrong recurved ſtipular ſpines in pairs. Leaves inſerted between the ſpines, alternate, unequally pinnate; leaflets from five to ſeven, alternate, ſubſeſſile, oblong, blunt. Panicle terminating, pubeſcent, ferruginous, compoſed of peduncles in a ſort of ſpike, directed one way, and hence toothed by the falling of the flowers all on one ſide. Spikes bent down and curved in, as in the *Aſperifoliæ*. Corolla white: ſtandard reflex, emarginate: wings oblong, oblique, with the tooth reverſed. Legume compreſſed, reniform or lunate, with the tip almoſt touching the baſe, valveleſs, without any leafy keel. Seed kidney-ſhaped, compreſſed, very large, being the ſize of the whole legume.

Native of South America, where it was found by Dalberg.

3. This is a very lofty tree, with the bark of the Alder, and alternate branches. Leaves alternate, petioled, ternate ſeldom pinnate, with four or five leaflets, which are alternate, petioled, the upper ones in the ſame pinna larger, ovate orbiculate or oblong, quite entire, emarginate or retuſe, very ſmooth above, hoary underneath. Stipules none. Racemes axillary, ſimple or branched, erect. Bractes none. Calyx brown. Standard of the corolla obcordate, erect, with the ſides bent back, toothletted, curled and waved, yellow with red veins: wings ſpreading, toothletted and waved at the edge, yellow: keel oblong, a little inflated, curled at the tip. Filaments yellow: anthers white. Germ hirſute: ſtyle curved. Legume pedicelled, ſmooth, keeled along the lower edge: keel membranaceous, ſomewhat waved, varicoſe with veins under the epidermis, not opening. Seed ſingle, orbicular, compreſſed, ſcarcely emarginate. It varies in the form of the leaves.

This is the true *Santalum rubrum*, which Koenig firſt detected in the Eaſt Indies. The wood is dark red with black veins, heavy, cloſe, capable of a good poliſh, and ſinking in water; it ſtains a beautiful red when moiſtened with water. The ſap yields one ſort of *Sanguis draconis*. Many of the red Indian woods tranſude a blood-red juice through the cleſts of the bark, which hardens into a red reſin, not differing from *Sanguinis draconis*; which therefore is collected from ſeveral trees, and this among others[a]. See *Calamus*, *Dalbergia*, *Dracæna*.

This drug however is chiefly obtained from the fruit of *Calamus Rotang*, expoſed to the ſteam of boiling water; or by boiling it, inſpiſſating the ſtrained decoction, and drying it in the leaves of ſome reed. The beſt kind breaks ſmooth, is of a dark red colour, and when powdered changes to crimſon; it readily melts and inflames: it totally diſſolves in pure ſpirit, and is ſoluble likewiſe in expreſſed oils, but not in water. It has no ſmell, but diſcovers ſome warmth and pungency to the taſte. It has been employed in hæmorrhages and alvine fluxes, but is now rarely uſed internally[b].

4. This is a ſhrub or a ſmall tree, with a branched even ſtem, and ſpreading even branches: branchlets flexuoſe, round, pubeſcent, villoſe. Leaves petioled, alternate, ſpreading in a double row, entire, nerved, pubeſcent. Petioles ſhort, round, thick, pubeſcent. Racemes ſcarcely longer than the petioles, axillary, almoſt ſimple, before flowering time convoluted: flowers numerous, directed one way, on very ſhort peduncles, white. Calyx ferruginous and ſilky on the outſide; the two upper teeth approximating; the three lower equal and acute. Standard of the corolla roundiſh, entire, ſomewhat compreſſed, covering the wings, veined: wings ſickle-ſhaped, contiguous to the keel, which is ovate, concave, bifid at the baſe, emarginate at the tip. Filaments in two bodies, five in each, diſtinct at top: anthers minute, roundiſh. Germ elongated, round: ſtyle curved in, aſcending, the length of the keel. Legume ſuborbicular, compreſſed like a leaf, opening; containing one compreſſed ſeed[c].

Native of the Weſt Indies. Browne ſays, that it is

[a] Linn. ſuppl. [b] Woodville. [c] Swartz.

not uncommon in the low lands about Kingſton, growing chiefly in ſwampy places, and running generally to the length of ſeven or eight feet, in an oblique direction from the root. When the plant is young, the more tender leaves are beſet with down; but this falls off as they grow more hardy, and in time they appear quite ſmooth.—This ſpecies was cultivated by Mr. Miller before 1733. Houſtoun ſent it from Carthagena.

5. See the deſcription of this under *Amerimnum Ebenus*, to which genus Swartz referred it, being very nearly allied to *Amerimnon* of Browne in the flower and fruit. It has ſomething in common with ſeveral plants of this claſs.

Native of the Weſt Indies. Cultivated in 1739 by Mr. Miller. It flowers in july and auguſt[1].

6. This is a tree, with ſmooth round branches, covered with a duſky aſh-coloured bark. Leaves alternate: leaflets three or four pairs, gradually larger outwards, alternate, ovate-oblong, acuminate, quite entire, ſmooth, ſhining, beautifully netted on both ſides with very numerous minute veins. Univerſal petioles often a ſpan long, flexuoſe, grooved above, ſlightly ſtriated beneath: partial petioles two lines long, wrinkled underneath at the inſertion of the leaf. Racemes axillary, ſhorter by half than the leaf, many-flowered: pedicels ſcattered, filiform, one-flowered, with two briſtle-ſhaped bractes in the middle. Flowers nodding. Legume an inch and half in length, ſmooth, veined in the middle, containing only one ſeed.—Found in South America by von Rohr *.

Leaves oppoſite, branches dichotomous divaricating.

3. Pteronia ſtricta. *Cluſter-flowered Pteronia.*
Ait. kew. 3. 162.
Leaves ſcattered and in bundles filiform ſubciliate at the baſe calycine leaflets entire, bellows of the receptacle many parted ſetaceous.

4. Pteronia flexicaulis.
Lin. ſyſt. 737. *ſuppl.* 355.
Leaves filiform ſmooth, calyxes commonly four-cornered, branches ſhort rigid.

5. Pteronia retorta.
Lin. ſyſt. 737. *ſuppl.* 356.
Leaves ovate reflex ſmooth ciliate at the edge and rugged, ſtem erect, calycine ſcales entire.

6. Pteronia hirſuta. *Hairy Pteronia.*
Lin. ſyſt. 737. *ſuppl.* 356.
Leaves lanceolate ſpreading hairy, ſtem procumbent, calycine ſcales entire.

7. Pteronia glabrata. *Smooth Pteronia.*
Lin. ſyſt. 737. *ſuppl.* 356.
Leaves lanceolate ſmooth, calycine ſcales ovate membranaceous.

8. Pteronia inflexa.
Lin. ſyſt. 738. *ſuppl.* 356.
Leaves ovate hairy, calycine ſcales ſubarticulate membranaceous, peduncle bent in.

9. Pteronia ſcariosa.
Lin. ſyſt. 738. *ſuppl.* 356.
Branches ſpiny, calyxes ſcarioſe, leaves oval.

10. Pteronia glomerata.
Lin. ſyſt. 738. *ſuppl.* 356.
Leaves ovate-three-ſided ſmooth, ſtem four-cornered.

11. Pteronia cinerea.
Lin. ſyſt. 738. *ſuppl.* 356.
Leaves oblong tomentoſe, calycine ſcales ovate membranaceous.

12. Pteronia villoſa.
Lin. ſyſt. 738. *ſuppl.* 356.
Leaves lanceolate blunt hairy, calycine ſcales ovate membranaceous.

13. Pteronia membranacea.
Lin. ſyſt. 738. *ſuppl.* 357.
Leaves ovate mealy tomentoſe, calycine ſcales awl-ſhaped ſcarioſe at the edge.

14. Pteronia ſpinoſa.
Lin. ſyſt. 738. *ſuppl.* 357.
Leaves awl-ſhaped ſpineſcent pungent.

15. Pteronia Cephaloides.
Lin. ſyſt. 738. *ſuppl.* 358.
Leaves awl-ſhaped felded together keeled ſerrulate, calyxes oblong terminating very minutely lacerated.

16. Pteronia pallens.
Lin. ſyſt. 738. *ſuppl.* 357.
Leaves filiform ſmooth, calyxes round ovate, ſtem and branches curved in round.

17. Pteronia minuta.
Lin. ſyſt. 738. *ſuppl.* 357.
Leaves linear wandering, flowers axillary.

18. Pteronia faſciculata.
Lin. ſyſt. 73 . *ſuppl.* 357.
Flowers in bundles each of one floret only.

DESCRIPTIONS, &c.

1. This is a ſhrub with rugged branches, three feet high. Leaves linear, very narrow, acute, flat, ſpreading. Flowers terminating, ſolitary, yellow, larger than thoſe of *Santolina* [a]. Receptacle flat, with deep chaffy cells, torn and briſtly at the top, and ſtiffiſh. Seeds ovate-oblong, compreſſed like a lens, ſmooth, of a ſort of cheſtnut colour or ferruginous. Down twice as long as the ſeed, lemon-coloured, caducous: rays filiform-ſetaceous, with longiſh cilias on both ſides or ſubplumoſe, connected at the baſe into a ring [b].—Native of the Cape of Good Hope.

2. This is a ſmall naked ſhrub, a palm in height; with oppoſite, dichotomous branches. Leaves ſmall, ſublanceolate, hoary or ſubtomentoſe. Flowers terminating, ſeſſile, yellow. Corollets deeply divided. Stigmas two, longiſh. Seeds hirſute. Down ſetaceous, hiſpid. Receptacle chaffy. *Dav. Reyen.*

It agrees with the genus of *Stæhelina*, but the down is not branched, nor the anthers tailed, nor the leaves alternate [c].

The flower is one of the largeſt of this order and genus. Calyx cylindrical, imbricate with cartilaginous even ſcales, ſubpubeſcent at the tip, membranaceous-attenuated at the edge. Receptacle honey-combed: cells with very ſhort margins, lacerate-ſetaceous, inclоſing a flatted teat. Seeds oblong, flatted thomb-ſhaped, hirſute, ſilky-white. Down ſetaceous, rigid,

[1] Hort. kew. * Vahl.

[a] Linn. mant. & amoen. [b] Gærtner. [c] Linn. ſyſt.

yellowiſh; with very numerous, ſubplumoſe rays, twice the length of the ſeed, faſtened cloſely to the top of it, but not uniting into a ring.

Pteronia therefore has much affinity with the *Capitatæ*, and accordingly is placed along with them by Juſſieu; but on account of its oppoſite or almoſt acerоſe leaves, and the receptacle not manifeſtly chaffy in all, it may keep its place among the *Diſcoideæ*[2].

3. This, with the two preceding, was introduced from the Cape of Good Hope by Mr. Francis Maſſon in 1774[3].

4 to 8. Found at the Cape of Good Hope by Thunberg.

9. Stem fruteſcent, ſtiff: with the barren branchlets ending in a ſpine. Leaves elliptic, ſeſſile, ſmall, even, quite entire, ſmooth, remote. Calyxes terminating, ſeſſile, cylindrical, imbricate, even, mucronate, ſcarioſe at the tip, with a broadiſh, hyaline, membrane. Diſk yellow, convex.—Native of the Cape of Good Hope.

10, 11, 12, 13. Found at the Cape of Good Hope by Thunberg.

14. Stem ſhrubby, woody, branched, round. Leaves alternate, ſeſſile, diſtant, ſlightly ſtriated, ſpreading very much, rigid, mucronate, permanent. Flowers four at moſt, (peduncled, *Retz.*) ſeſſile in the uppermoſt axils of the leaves, eſpecially at the ends of the branches, imbricate, cylindrical; with blunt ſcales.—Native of the Cape of Good Hope.

15. This is a ſmooth and even proliferous ſhrub. Leaves remotely oppoſite, an inch long, ſerrulate along the edge and keel. Flowers terminating, erect. Calyxes large, thick, imbricate: ſcales ovate, ſcarioſe, blunt, very finely lacerated and ciliate. Seeds obovate, biggiſh. Down ſimple, denſe, faſtigiate. Receptacle naked; and therefore it is rather a *Chryſocoma*. Native of the Cape of Good Hope.

16. This is an unequal ſhrub, with whitiſh branches, like *Galenia*. Leaves oppoſite, linear, ſomewhat branched. Corymbs three-flowered, terminating, yellow.—Native of the Cape.

17. Stems a palm high, with the branches dichotomous above. Leaves alternate or oppoſite, every where ſubpubeſcent. Flowers from the forkings of the ſtem, ſubſeſſile, the ſize of Lithoſpermum ſeeds. Calyx even. Florets minute, few.—Native of the Cape.

18. Stem ſhrubby, dichotomous, with ſcales mucronate on each ſide on the branchlets. Leaves oppoſite, imbricate, erect, an inch long, lanceolate, ſlightly keeled, reſinous. Bundles of flowers faſtigiate, yellow, terminating, ſeſſile. Calyxes oblong, imbricate: leaflets lanceolate, acute.—Found by Thunberg at the Cape of Good Hope.

The habit of theſe plants is ſingular and peculiar; but ſome of the ſpecies having a naked receptacle, ought rather to be placed in the genus Chryſocoma: either therefore a new generic character ſhould be conſtructed for Pteronia, or the natural genus torn aſunder[4].

Calyx abbreviated, leaves ovate glaucous, ſtem branched procumbent.]

DESCRIPTIONS, &c.

1. This has leaves much narrower than thoſe of the common ſort, (officinalis, n. 2.) and covered with ſoft hairs, not ſpotted. The ſtalks riſe a foot high, and have narrow leaves on them, of the ſame ſhape with thoſe below, but ſmaller, and almoſt embracing. The flowers are produced in bunches on the top of the ſtalks, like the others: the corollas are red before they expand, but when they are fully blown are of a moſt beautiful blue colour. [It varies with a white flower. Linneus remarks, that it is ſcarcely different from the next ſpecies, except in the narrowneſs of the leaves. Haller ſays it differs from the following in having a higher ſtalk, attaining to three feet; narrower leaves, the lower elliptic and blunt, the upper ſhort, heart-ſhaped, ſeſſile, decurrent into the long petiole, four or five inches in length, and one inch in breadth. Flowers in bundles at the top, with green ſtipules between them. Calyx hirſute, five-toothed, very wide during the maturity of the plant, not divided to the middle.

Native of Sweden, Denmark, Germany, Switzerland, Auſtria, Hungary, France and Italy. It is ſaid by Johnſon, upon Gerarde, to have been found by Mr. Goodyer in a wood by Holbury-houſe, in the New Foreſt, Hampſhire. Mr. Robſon informed Dr. Withering, that he had a ſpecimen ſent him in the year 1783, by the late Mr. Waring, of Leeſcrood in Flintſhire, who found it growing wild on the ruins of the monaſtery Maes Glas. But Dr. Smith thinks that the leaf ſent by Robſon out of Wales, belonged rather to *Symphytum tuberoſum*. Pulmonaria anguſtifolia therefore muſt be conſidered at preſent as a doubtful native of Britain.]

β. Leaves large, ſpear-ſhaped, rough: foot-ſtalks of the lower leaves broad. Stalks a foot high, with ſpear-ſhaped, half-embracing leaves. The leaves are greatly ſpotted with white, appearing as if they were incruſted with ſugar-candy. Flowers in large bunches on the top of the ſtalk. Tube of the corolla longer than the calyx, and the brims ſpreading more than thoſe of the common ſort. The colour is a bright blue; and they appear in april and may.

Native of the mountains of Switzerland, [Auſtria and Hungary. It was cultivated by Mr. Miller in 1731[1].]

2. Root perennial, fibrous. Lower leaves rough, about ſix inches long, and two inches and a half broad, of a dark green on their upper ſide, marked with many broad whitiſh ſpots, but pale and unſpotted on their under ſide. Stalks almoſt a foot high, having ſeveral ſmaller leaves on them ſtanding alternately. The flowers are produced in ſmall bunches at the top of the ſtalks: calyx tubulous, hairy, as long as the tube of the corolla; brims of the petal ſpread open, and ſhaped like a cup, red purple and blue in the ſame bunch.

[Leaves hairy on both ſides: root-leaves petioled, ovate or ſubcordate; ſtem-leaves ovate, ſeſſile, embracing. (Lower leaves much lengthened out at the baſe, of a light green; the upper ones only, which are ovate and rather broad, being ſpeckled with white on the upper ſide: this however is a variable circumſtance.) Stem ſimple, erect, angular and rough. Racemes in pairs, ſhort, terminating. Calyx roughhaired. Corolla blue, before it expands red[a]: varying as the preceding with white flowers.

Native of Europe in woods and ſhady places, flowering from march to may. I found it at La Batie near Geneva in flower, on the 15th of march, 1779. In Britain, though common in every garden, it is unfrequent in a wild ſtate. Mr. Abbot found it between

[1] Hort. kew. [a] Smith.

Thurleigh and Milton-Ernys in Bedfordſhire; Mr. E. Robſon, in Cliff-wood, ſix miles weſt of Darlington; and if this be Goodyer's plant, it is an inhabitant of the New Foreſt. Dr. Milne found it in ſeveral woods of Kent, and between Croydon and Godſtone in Surry.

The leaves, which are the part recommended in medicine, have no peculiar ſmell, but in their recent ſtate manifeſt a ſlightly aſtringent and mucilaginous taſte; hence they are ſuppoſed to be demulcent and pectoral, and have been uſed in hemoptoes, tickling coughs, and catarrhal defluxions upon the lungs.

The name *Pulmonaria* ſeems however to have ariſen rather from the ſpeckled appearance of theſe leaves, reſembling that of the lungs, than from any intrinſic quality which experience has diſcovered to be uſeful in pulmonary complaints [a].

Moſt plants in this natural claſs of *Aſperifoliæ* are far more mucilaginous than this; which according to Linneus, when burnt, affords frequently one ſeventh of its weight in aſhes.

3. Stems woody at bottom, perennial with the leaves. Flowering-ſtems quite ſimple, ſomewhat hairy. Leaves almoſt filiform, ſcattered, hiſpid, long. Flowers in bundles, terminating, with the calyxes ſhorter by half than the corolla.—Found by Seguier and Arduini in the mountains of Italy [b].

4. Native of Hudſon's Bay. Introduced in 1778 by Daniel Charles Solander, L.L.D. It flowers in may and june; and varies from blue to white flowers [c].]

5. Root perennial, thick, fleſhy; ſending out many ſmall fibres. Stalks a foot and half high, dividing at the top into ſeveral ſhort branches. Leaves near the root four or five inches long, two inches and a half broad, ſmooth, of a light green, on ſhort foot-ſtalks: thoſe upon the ſtem diminiſh in their ſize upwards, but are of the ſame ſhape and ſeſſile. Every ſmall branch at the top of the ſtalk is terminated by a cluſter of flowers, each ſtanding upon a ſeparate ſhort peduncle: their calyxes are very ſhort, and are cut into five ſegments almoſt to the bottom; the tube of the flower is long, and at the top ſpreads open in ſhape of a funnel, the brim being entire, but appears five-cornered from the folding of the petal. The moſt common colour of theſe flowers is blue, but there are ſome purple, others red and ſome white: they appear in april, and if they have a ſhady ſituation, will continue in beauty great part of may; and ſometimes are ſucceeded by ſeeds in England. The leaves and ſtalks entirely decay in auguſt, and the roots remain naked till the following ſpring.

It grows upon mountains in moſt parts of North America. The ſeeds were ſent many years ſince by Mr. Baniſter from Virginia, and ſome of the plants were raiſed in the Biſhop of London's garden at Fulham. [According to the Kew catalogue it was cultivated in 1699 in the botanic garden at Chelſea.

Mr. Curtis remarks, that the leaves are glaucous; that the flowers before they expand are of a reddiſh purple colour, but when fully blown become of a light bright blue; and that it is ſaid to vary with white and fleſh-coloured flowers. In favourable ſeaſons, the flower-garden owes much of its gaiety to this elegant plant, at a time when ornament is moſt deſirable.

6. Root perennial. Leaves ſmooth, glaucous. Stem-leaves ovate. Corymbs branched, nodding. It is a middle ſpecies between the preceding and following.—Native of Siberia [d].

7. Root perennial, (or biennial) woody, blackiſh. Stems numerous, procumbent, a foot or more in length, nearly round, leafy, much branched above. Leaves numerous, ſcattered, ſeſſile, pointed, narrowed at the baſe, perfectly entire, ribbed on the under ſide, waved, the point moſt commonly bent back, the upper ſurface rugged with fine prominent points. Racemes leafy, terminating. Flowers on longiſh, ſimple, round peduncles, a little thickened next the flowers, and ſomewhat warted, one or two together, ſometimes axillary, and generally cluſtered about the extremities of the branches. Calyx glaucous, ſhorter than the tube, divided almoſt to the baſe, where it is a little priſmatic, into five ovate acute ſegments. Corolla with a ſhort thick tube, and a ſmall border in five obtuſe ſegments, red at firſt, then blue; orifice a little toothed, but pervious. Stamens inſerted about the middle of the tube, and projecting beyond the orifice. Stigma capitate. The whole plant turns black in drying, unleſs it be firſt immerſed in freſh water for twenty-four hours to extract the ſea ſalt, according to Dillenius [e].

Native of Norway, Iceland, Britain. It is a great ornament of ſandy ſea-coaſts, in Scotland and the north of England; flowering in july. The roots ſtrike deeply into the ſand, or among the pebbles. It is mentioned by Ray as found by Mr. Lawſon at Scrammerſton Mill, between the ſalt-pans and Berwick; alſo near Whitehaven in Cumberland, and againſt Bigger in the Iſle of Walney in Lancaſhire; by Mr. Lhwyd near Treſarthen in Angleſea, and by the river Uyſni in the way from Dinardindle to Clynog in Caernarvonſhire; by Dr. Sibbald in ſeveral places along the ſouth ſide of the Firth of Forth; by Mr. Lightfoot on the coaſt of Fife, near St. Andrew's, &c. in the Iſle of Bute, in Arran at Loch-Ranſa, and at Lamlath, at Icolumb-kill, and at Glen-Elg, in Inverneſſhire, &c.; by Mr. Dickſon at the ferry on the ſea ſhore near Inverneſs; near Maryport in Cumberland by Mr. Harriman; about Aberdeen by Mr. Browne; on the weſt ſhore of the Iſle of Walney by Mr. Atkinſon.

Dr. Blair relates, in his Miſcellaneous Obſervations, p. 55. that he was credibly informed by a gentleman, that in the late famine, one of his farmers being ſtraitened for bread, taking this plant for Colewort, to which it is not unlike in colour, ordered to boil a diſh of it, and gave it to his wife and children, with the ſervants in his family; all of them became very ſick, ſome vomited exceſſively, others ſlept two or three days without intermiſſion, and one or two of them died.—Had Blair related this of his own knowledge, I ſhould have been inclined to believe it; but the gentleman might be miſtaken in the plant; and the Aſperifoliæ, as far as we know, betray no ſymptoms of a narcotic quality.

The four laſt ſpecies are very nearly allied; having an upright ſtem, the tube of the corolla longer than the border, the root-leaves cordate, and the ſtem very much branched; whoever regards them as varieties, will ſcarcely be miſtaken [f].]

PROPAGATION AND CULTURE.

Theſe plants having perennial roots, may be cultivated by parting their roots, which may be done either in the ſpring, or autumn; but if the ground be moiſt into which they are planted, it is better to be done in the ſpring, otherwiſe the autumn is preferable, that the plants may be well rooted before the dry weather comes on in the ſpring, which will cauſe them to flower much ſtronger.

The ſoil in which they are planted ſhould not be rich, but rather a freſh light ſandy ground, in which they will thrive much better than in a richer ſoil, in which they are very ſubject to rot in the winter. They ſhould have a ſhady ſituation, and thrive beſt in a moiſt ſoil, for in a hot dry ſoil they burn and decay in ſummer, unleſs they are duly watered in dry weather. All the early ſorts are better tranſplanted, and parted in autumn, that they may be well rooted to flower ſtrong the following ſpring. The fifth ſort ſhould not have a ſoil too moiſt, for as the roots run deep in the ground, they will be in danger of rotting by much wet.

They may alſo be propagated by ſeeds ſown in autumn, ſoon after they are ripe, where they are to remain, for the ſeedling plants do not ſucceed ſo well when they are tranſplanted. The common ſorts will come up from ſcattered ſeeds.

[5. Mr. Curtis remarks that P. virginica requires a pure air, and a ſituation moderately ſheltered, as the cold cuſterly winds in april, when it is in flower, are apt to deface it.

[a] Woodville. [b] Linn. ſpec. [c] Hort. kew. [d] Linn. ſpec. [e] Curtis and Smith. [f] Linn. ſpec.

7. Gather the seeds as they ripen, for by staying for the last-blown flowers, the seeds from the first will have fallen out: sow them either early in september or the ensuing february, in a pot of earth compofed of three parts sea sand, or common sand, and one part rotten cow-dung, finely sifted; in about six weeks or two months from the february sowing these seeds will vegetate, and in the autumn the plants will be fit to transplant into separate pots, and most of them will flower the ensuing year. Snails and slugs are uncommonly fond of this plant; if therefore it be planted in the open border, it will in all probability be destroyed. Set them with the greenhouse plants, and treat them as such. Water them over the leaves as little as may be, for the water is apt to settle on them in drops, and to leave marks which greatly disfigure them [4].

PULMONARIA. See *Hieracium* and *Lichen pulmonarius*.

PULSATILLA. See *Anemone* and *Atragene*.

PULTENÆA. *(So named by Dr. J. E. Smith, in honour of my much esteemed friend William Pulteney, M.D. of Blandford in Dorsetshire, whose writings have so essentially contributed to the introduction and establishment of Linnean botany in this country.)*

Class. 10. 1. Decandria Monogynia.

GENERIC CHARACTER.

CAL. five-toothed, with an appendage on each side.
COR. papilionaceous; the wings shorter than the standard.
LEGUME of one cell, with two seeds.

SPECIES.

1. Pultenæa stipularis.
Smith, bot. N. Holl. p. 35. t. 12. Curt. magaz. 475.
With linear mucronated subciliated leaves, and solitary two-nerved lacerated stipules.
2. Pultenæa paleacea.
Willdenow, sp. pl. 506.
With linear mucronated smooth leaves, terminal head, and oblong-acuminate toothed bractes longer than the flower.
3. Pultenæa linophylla.
Willdenow, sp. pl. 506. Schrad. et Wendl. sert. hannov. p. 28. t. 18. (bracteata.)
With linear obtuse mucronated strigose leaves, few-flowered terminal heads, and scarious bifid bractes much shorter than the calyx.
4. Pultenæa juncea.
Willdenow, sp. pl. 506.—Sophora juncea. *Schrad. & Wendl. sert. hannov. p. 9. t. 3.*
With filiform leaves with cartilaginous-trifid tips, terminal raceme, unappendiculated cups, and extipulated stem.
5. Pultenæa villosa.
Willdenow, sp. pl. 507.
With oblong hairy leaves, solitary axillary flowers, and villose stem.
6. Pultenæa daphnoides.
Willdenow, sp. pl. 507.
With smooth obovate mucronated leaves, and terminal headed flowers.

DESCRIPTIONS, &c.

1. The stem of this species is shrubby, variously branched, and round; the wood hard and whitish; bark brown, covered more or less with withered bristly stipules: branches long and straight, pointing upwards, clothed with leaves, and terminated by round heads of handsome yellow inodorous flowers. The leaves surround the branches in great numbers without any regular order, and are linear, very narrow, tipped with a little sharp point, entire, smooth, without any projecting vein or nerve, most frequently ciliated with fine stiff hairs. Footstalks very short, pale and smooth, erect at night, by which the leaves become closely pressed to the branch, and imbricated one over the other, though in the day time, and especially in bright sunshine, they spread horizontally. The very remarkable stipules stand solitary just above the insertion of each footstalk, erect and close pressed to the branch, the bark of which they by that means completely conceal; they are brown, of a chaffy texture, lanceolate, cloven, and sometimes laciniated, furnished with two parallel nerves. The flowers are about twenty or more, in a round head, among spreading leaves, and the branch they at first terminate is at length sometimes protruded a little beyond them, by which they become verticillate; each stands on a short, round, smooth flower-stalk, with bractes like the leaves, but smaller, and likewise accompanied with stipules. Calyx slightly campanulate, red, divided half way down into five acute, spreading, ciliated teeth, of which the two uppermost are the shortest and broadest; between them and the next pair stand the two appendages which make a material part of the generic character, and which agree exactly in appearance with the proper teeth, except in being somewhat narrower, and inserted, one on each side, about half way down the entire part of the calyx, to which their lower end is closely applied, so that they make the calyx appear to have seven teeth of equal length. Corolla of five petals. Standard with a firm horizontal claw, its limb erect, round, slightly notched, the two sides generally folded together, deep yellow, with a red semicircular line near the base. Wings nearly linear, obtuse, concave, with a large tooth at the base, deep yellow, horizontal, much shorter than the standard. Keel of two pale yellow obovate concave petals as long as the wings, strongly connected by their lower edge, and with a tooth near their base on the upper. Stamens all nearly equal, somewhat shorter than the keel, a little declining; filaments inserted into the receptacle, cylindrical, tapering to a point: anthers small and roundish: germ small, green, oval, smooth, tipped with a tuft of white hair, and containing the rudiments of two or three seeds: style longer than the stamens, subulate, recurved, smooth: stigma acute. Pod scarcely longer than the calyx, roundish, pointed, turgid, brown, hairy at the extremity, of one cell, containing two seeds on short footstalks, inserted into the upper edge of each valve, near the base. The plant appears to abound in mucilage, especially the leaves.

Native of New Holland. First flowered in England in april 1794. Described by Dr. Smith.

2. Native of New Holland.

3. A shrub of six feet high; upright, stem branching, brown, branches alternate, subdividing into smaller, covered with a silky pubescence. Leaves scattered, thickish, green, paler beneath. Stipules two, opposite, upright, sharp, brown-ferruginous. Head consisting of four or six flowers, upright, sessile, involucrated by bractes, which are imbricate, ovate, bifid, scarious, and reddish-brown. Flowers pale orange: standard marked in the middle by a semilunar radiated purple spot: keel of a purplish violet colour.—Native of New Holland.

4. This, which is described and figured by Schrader as a species of Sophora, is a small upright smooth shrub of about two or three feet high, with simple branches growing at pretty acute angles or upright; the leaves have the appearance of a kind of long green spines, but when the plant is young there are some footstalked oval-lanceolate leaves without stipules. Flowers yellow: standard marked with a semilunar radiated red spot.

Native of New Holland. Bears the open air very well in summer, but should be housed in winter.

5. Native of New Holland.

6. A shrub of about three feet high, with an upright, silky, branching stem; leaves alternate and silky; heads consisting of six or eight flowers, with silky involucre, and hollow hairy stipule.—Native of New Holland.

DESCRIPTIONS, *&c.*

1. This tree riſes with a woody ſtem eighteen or twenty feet high, ſending out branches the whole length, which likewiſe put out many ſlender twigs, rendering it very thick and buſhy. Some of theſe are armed with ſharp thorns. The leaves are narrow ſpear-ſhaped, about three inches long, and half an inch broad in the middle, drawing to a point at each end; they are of a light lucid green, and ſtand oppoſite. The flowers come out at the ends of the branches, ſingly or three and four together; frequently one of the largeſt terminates the branch, and immediately under that are two or three ſmaller buds, which continue a ſucceſſion of flowers for ſome months. The calyx is very thick and fleſhy, and of a fine red colour. The petals are ſcarlet.

[The fruit, according to Linneus is a pome, but according to Gærtner an inferior berry, crowned with the tube of the calyx, which is ſharply toothed, globular a little flatted, covered with a hard coriaceous rind including a pulp, divided into two unequal chambers by a tranſverſe diaphragm. The upper chamber is larger, with from ſeven to nine cells, ſeparated from each other by a very thin membranaceous partition: the lower chamber is much ſmaller, hollowed conically upwards, divided into three cells by very tender membranaceous partitions. In the upper chamber the receptacles are wedge-ſhaped proceſſes of a fleſhy ſubſtance, tending from the walls of the berry towards the axis, and hollowed on every ſide into little pits, into which the ſeeds are inſerted: in the lower chamber the proceſſes are irregular, or it is the bottom of the berry, hollowed into many cells irregularly, in which the ſeeds are fixed. Theſe are variouſly angular, pellucid, commonly tinged with red, and ſhining like cryſtal *.]

Native of Spain, Portugal, Italy, Barbary, Perſia, Japan, China, Cochinchina, &c. In the Weſt Indies, where it is ſuppoſed to have been introduced from Europe, the fruit is larger and better flavoured.

The varieties are—

The wild Pomegranate with ſingle and double flowers.

The ſweet Pomegranate.

The ſmall-flowering Pomegranate with ſingle and double flowers.

The Pomegranate with ſtriped flowers.

[The rind of the fruit, and the flowers are the parts directed for medicinal uſe. They are both powerful aſtringents, and have long been ſucceſsfully employed as ſuch both internally and externally, in gargles, in diarrhœa, &c. The doſe in ſubſtance is from half a dram to a dram; in infuſion or decoction, to half an ounce †.

It was cultivated in 1596, by Gerarde ‡.

The wild, I think, (ſays Parkinſon) was never ſeen in England, before John Tradeſcante my very loving good friend brought it from the parts beyond the ſeas, and planted it in his Lords garden at Canterbury.]

2. The dwarf Pomegranate ſeldom riſes more than five or ſix feet high. The flowers are much ſmaller than thoſe of the common ſort; the leaves are ſhorter and narrower; the fruit is not larger than a nutmeg, and has little flavour: but it may be kept within compaſs; and in the Weſt Indies, where it is a native, and is planted for hedges, it continues flowering great part of the year.—[It is cultivated in Cochinchina, according to Loureiro.]

PROPAGATION AND CULTURE.

The ſingle Pomegranate is now pretty common in the Engliſh gardens, where formerly it was nurſed up in caſes, and preſerved in green-houſes with great care (as was alſo the double flowering kind); but they are both hardy enough to reſiſt the ſevereſt cold of our climate in the open air; and, if planted againſt warm walls in a good ſituation, the firſt will often produce fruit, which in warm ſeaſons will ripen tolerably well; but as theſe fruits do not ripen till late in the autumn, they are ſeldom well taſted in England, for which reaſon the ſort with double flowers is commonly preferred to it. The ſort with ſweet fruit, as alſo the wild ſort, are leſs common in the Engliſh gardens than the former two.

Theſe plants may be eaſily propagated by laying down their branches in the ſpring, which in one year's time will take good root, and may then be tranſplanted where they are deſigned to remain. The beſt ſeaſon for tranſplanting theſe trees is in ſpring, juſt before they begin to ſhoot; they ſhould have a ſtrong rich ſoil, in which they flower much better, and produce more fruit than if planted on dry poor ground; but in order to obtain thoſe in plenty, there ſhould be care taken in the pruning of theſe trees, for want of which we often ſee them very full of ſmall ſhoots, but do not find many flowers produced upon them; therefore I ſhall ſet down directions for pruning theſe trees, ſo as to obtain a great quantity of flowers and fruit.

The flowers of this tree, always proceed from the extremity of the branches which are produced the ſame year. This therefore directs, that all weak branches of the former year ſhould be cut out, and that the ſtronger ſhould be ſhortened in proportion to their ſtrength, in order to obtain new ſhoots in every part of the tree. The branches may be laid in againſt the wall about four or five inches aſunder; for, as

* Gærtner. † Woodville. ‡ Hort. kew.

their

their leaves are ſmall, there is not a neceſſity of allowing them a greater diſtance. The beſt time for this work is about Michaelmas, or a little later, according to the mildneſs of the ſeaſon, for if they are left until ſpring before they are pruned, they ſeldom put out their ſhoots ſo early, and the earlier they come out, the ſooner the flowers will appear, which is of great conſequence where fruit is deſired. In ſummer they will require no other dreſſing, but to cut off all vigorous ſhoots which grow from the wall, and never produce flowers (for it is the middling ſhoots only which are fruitful;) and when the fruit is formed, the branches on which they grow ſhould be faſtened to the wall to ſupport them, otherwiſe the weight of the fruit, when grown large, will be apt to break them down.

Though, as I ſaid before, the fruit of this tree ſeldom arrives to any perfection in this country, ſo as to render it valuable; yet, for the beauty of its ſcarlet-coloured flowers, together with the variety of its fruit, there ſhould be one tree planted in every good garden, ſince the culture is not great which they require; the chief care is to plant them upon a rich ſtrong ſoil, and in a warm ſituation. Upon ſome trees which had theſe advantages, I have obtained a great quantity of fruit which have arrived to their full magnitude, but I cannot ſay they were well flavoured; however, they made a very handſome appearance upon the trees.

The double flowering kind is much more eſteemed than the other in this country for the ſake of its large, fine, double flowers, which are of a moſt beautiful ſcarlet colour; and, if the trees are ſupplied with nouriſhment, will continue to produce flowers for two months ſucceſſively, which renders it one of the moſt valuable flowering trees yet known. This muſt be pruned and managed in the ſame manner as hath been already directed for the fruit-bearing kind, but this ſort may be rendered more productive of its beautiful flowers by grafting it upon ſtocks of the ſingle kind, which will check the luxuriancy of the trees, and cauſe them to produce flowers upon almoſt every ſhoot; by which method I have had a low tree, which was planted in the open air, extremely full of flowers, which made a very fine appearance.

2. The dwarf Pomegranate may be propagated by layers, like the former, but muſt be planted in pots filled with rich earth, and preſerved in a greenhouſe. In the ſummer, when the flowers begin to appear, if the plants are expoſed to the open air, the buds will fall off without opening; they ſhould be placed therefore in an airy glaſs caſe, and a large ſhare of air ſhould be given them every day in warm weather. By this treatment the plants may be continued in flower upwards of three months, and will make a fine appearance.

Peduncle one-flowered.

DESCRIPTIONS, *&c.*

1. Root creeping. Stems angular, short, leafy. Leaves alternate, petioled, roundish, obsoletely serrate, very smooth. Peduncle terminating, a span long, with scattered bractes. Raceme terminating, almost upright, many-flowered. Pedicels alternate, with a lanceolate bracte at the base. Flowers nodding, white. Stamens ascending to the upper side of the flower. Anthers bent in and hanging down, four-grooved, awnless, with two subtubular pores at the base. Germ depressed, five-grooved. Style declining, recurved at the tip, longer than the stamens. Stigma wheel-shaped, five-tubercled [a]. Capsule globular, umbilicated, rounded-five-cornered, five-celled, five-valved: partitions contrary to the valves. Receptacle five-lobed, fungous, fastened to the axis; with the lobes convex, attenuated downwards, hanging down within the cells. Seeds very numerous and very small, consisting of a globular nucleus, within an arilius, shaped like sawdust [b].

Leaves and flowers larger than in the next species. Calyx longer and more lanceolate; but the essential difference consists in the stamens being all bent as if for shelter towards the upper side of the flower; while the style, much longer than that of P. minor, is curved downwards in as singular a manner, and again recurved to catch the pollen. The stigma terminates in five blunt tubercles [a].

Native of the northern parts of Europe, Germany, Switzerland, the South of France and the North of Italy. In Britain not common: found on a common at Bradwell near Gorleston in Suffolk, by Mr. Wigg. In some woods of Scotland by Mr. Donn. It flowers in july.

2. This has the habit of the preceding, but is smaller. Peduncle almost naked, or only with a single bracte. Raceme erect. Flowers smaller, often reddish. Stamens spreading on every side. Pores of the anthers dilated, not tubular. Style very short, straight. Stigma peltate [c].

Native of the north of Europe: in Scotland and the north of Yorkshire; in Stokenchurch woods Oxfordshire; Whipsnall and woods about Luton, found by Mr. Abbot; near Tring in Hertfordshire, by Mr. Woodward. It is the species found in most of the places of growth mentioned for P. rotundifolia, as Hackfall woods, &c. It is in a manner naturalized in the Duke of Portland's wood at Bulstrode, where it was planted by Mr. Lightfoot [a].

3. Roots small and fibrous. Stems procumbent, alternately branched, with the branchlets erect and leafy. Leaves on longish petioles, spreading, ovate, acute, finely serrate, netted with veins, smooth on both sides, of a bright pleasant green. Peduncles terminating, solitary, with a few scattered bractes. Racemes many-flowered. Flowers all leaning to one side, greenish white, a little drooping, each having a bracte at the base of the pedicel. Calyx small. Petals oblong, concave. Anthers as in P. minor. Style long, straight, permanent. Stigma peltate, gibbous [a].

Native of woods in the north of Europe; and even in Switzerland, France and Italy. In fir and birch woods in the highlands of Scotland. Ray had it from Yorkshire. Mr. Miller found it in Westmoreland.

4. Root very long. Stem upright or a little decumbent at the base, naked at bottom hard and woody, roughened here and there with tubercles. Leaves opposite, or heaped in whorls or scatteringly in the middle of the stem and branches, cuneiform-lanceolate, blunt, serrate, rigid, dark green above, pale green beneath, smooth, shining, hard, decurrent into the petiole, subsessile, from one to two inches in length, from four to six lines in width, broader at the top, narrower at the base. The common peduncle is continued from the stem and branches, and at the top of it are three or four peduncles bearing each one flower, forming a sort of umbel and hanging down. Flowers reddish white. Anthers whitish. Stigma capitate, obtuse [a]: according to Retzius, subsessile, large, orbicular, hollowed in the middle.

Native of Europe, Asia and North America, in woods, particularly fir woods, and such as are very old, shady and desert. Indeed all the Pyrolas, as Linnæus remarks, delight in deep shade and a rocky or barren soil.]

5. Root woody. Stems two or three, woody, a foot and half high. Leaves stiff, two or three inches long, an inch broad near the base, ending in acute points, and having some sharp indentures on their borders; the midrib is remarkably broad and very white, as are also the veins which run from it. The flowers are produced at the end of the stalk on slender peduncles about three inches long, each sustaining two small pale-coloured flowers at the top. It flowers in june.

6. The long branched roots run deep among moss in moist alpine woods. Every part is smooth. Stems short, simple, angular, leafy. Leaves obovate, blunt, serrulate, smooth, petioled. Peduncle solitary, longer than the leaves, upright, bearing one flower, larger than in the other species, of great elegance, possessing all the fragrance of Lily of the valley. Both corolla and calyx sometimes streaked externally with red. Linnæus and Haller have observed that the stamens are not placed regularly with respect to the petals, some of the latter having three stamens next them, others two, and others but one. The anthers are of a most curious figure, four-lobed, with two tubes at the base, by which probably the pollen is discharged. The style is straight. The stigma resembles a five-rayed crown [a].

Native of woods in the northern parts of Europe: in Germany, Carniola, and even the South of France and the north of Italy. In Britain it was not known to grow wild till Mr. James Hoggan found it about the year 1783, on the islands of Harris and Bernera among the Hebrides; and Mr. James Hoy in fir woods near Brodie-house in Moray [a].

The species may be distinguished by the stigma; which in *rotundifolia* is incrassated, five-toothed, with the teeth upright and acute. That of *uniflora* exactly resembles this, except in being larger and peltate. In *minor* it is peltate, convex, five-lobed. So it is in *secunda*; but in the latter it is punched with five pores. In *umbellata* it is subsessile, large, and hollowed in the middle [a].]

PROPAGATION AND CULTURE.

These plants are all very difficult to cultivate in gardens, for as they grow on very cold hills, and in mossy moorish soil; they seldom continue long, when removed to a better soil, and a warmer situation.

The best time to transplant them into gardens is about michaelmas, when the roots should be taken up with balls of earth to them, and planted in a shady situation, and on a moist undunged soil, where they should be frequently watered in dry weather. Or they may be planted in pots, filled with the same earth in which they grow, placed in a shady situation, in pans of water, or at least constantly watered in dry weather.

PYROSTRIA. (Pyrus ſtriata; *the fruit being like a pear, but ſtriated.*)
Willd. ſpec. 614. *Juſſ. gen.* 206.
Claſſ. 4. 1. Tetrandria Monogynia.
Nat. order of *Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. very ſmall, four-toothed.
COR. bell-ſhaped, five-cleft, tomentoſe in the throat.
STAM. four.
PIST. one. *Stigma* capitate.
PER. *Drupe* pear-ſhaped, inferior, ſmall, eight-ſtreaked, not crowned.
SEED. *Nuts* eight, one-ſeeded.

SPECIES.

1. Pyroſtria ſalicifolia.
Willd. ſpec. 614. *Lamarck, encycl. t.* 68. *f.* 4.

DESCRIPTION, *&c.*

Leaves oppoſite, petioled, bluntiſh, attenuated at the baſe, quite entire. Peduncles axillary, three or four-flowered[t].
It is a ſmall tree. Peduncles one, or many-flowered. Number of cells ſometimes various. Stipules caducous[t].—Native of the iſland of Mauritius.

PYRROCHITON. See *Ornithogalum.*]

PYRUS. (*Pirus of Pliny. Suppoſed to be from* πυρ, *fire; the fruit drawing up to a point, like flame.*)

Claſſ. 12. 4. Icoſandria Pentagynia.
Nat. order of *Pomaceæ. Roſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, concave, five-cleft, permanent: *ſegments* ſpreading.
COR. *Petals* five, roundiſh, concave, large, inſerted into the calyx.
STAM. *Filaments* twenty, awl-ſhaped, ſhorter than the corolla, inſerted into the calyx. *Anthers* ſimple.
PIST. *Germ* inferior. *Styles* five, filiform, the length of the ſtamens. *Stigmas* ſimple.
PER. *Pome* roundiſh, umbilicate, fleſhy, with five membranaceous cells.
SEEDS ſome, oblong, blunt, acuminate at the baſe, convex on one ſide, flat on the other.
OBS. *It is ſurpriſing there has been a general conſent to ſeparate this well known genus into three, by making genera of ſpecies, and ſpecies of varieties.*

ESSENTIAL CHARACTER.

Cal. five-cleft. *Petals* five. *Pome* inferior, five-celled, many-ſeeded.

Leaves linear-lanceolate hoary white-tomentoſe underneath, flowers axillary ſolitary ſubſeſſile.

DESCRIPTIONS, &c.

1. The Pear grows to a lofty tree, with upright branches, but the twigs or branchlets hanging down. Leaves elliptical, obtuſe, ſerrate; the younger ones clothed with a deciduous cotton underneath and along the edge. Stipules linear. Flowers in terminating villoſe corymbs. Corolla ſnow-white. Pome produced at the baſe, hard and acerb (in the wild ſtate), with five cells in the middle, each two-valved, and (regularly) containing two ſeeds[a].

Gærtner calls this fruit a Berry, and deſcribes it as inferior, ſubturbinate, fleſhy: the fleſh or pulp ſolid, with ſtony concretions near the cells, which are lined with a coriaceous elaſtic levigated membrane. Seeds in each cell two, obovate, acuminate downwards, plano-convex, ſmooth, dark cheſtnut-coloured. It varies ſometimes with four two-parted one-ſeeded cells:—and ſome of the ſeeds are generally wholly wanting or abortive, at leaſt in the cultivated Pears.

The wild Pear, the mother of all the orchard and garden varieties is thorny[b]. The ſtipules are ſetaceous, white (or reddiſh), deciduous: the peduncles alternate: the calyx clothed with a ferruginous wool[c].

The wood of the Pear is light ſmooth and compact: it is uſed by turners and to make joiners tools; and for picture frames, to be ſtained black. The leaves afford a yellow dye, and may be uſed to give a green to blued cloths. The juice of the fruit fermented is called Perry. The Squaſh, Oldfield and Barland Perrys are reckoned the beſt, and are little inferior to wine[d].

The Pear is a native of Europe. It is not known whence the numerous cultivated varieties are derived. This fruit was familiar to the ancients, and has long been a great favourite with the French. It was doubtleſs not unknown to our remote anceſtors, but does not ſeem to have been in equal favour with them as with their neighbours.

In an account book of Henry VIII. now remaining in the Exchequer, there are the following charges, among others—

For Medlars and Wardens (Pears)	-	0	3	4
Item to a woman who gaff the Kyng Peres		0	0	2
Item to a woman for three Apples	-	0	0	12

Chaucer mentions the Pear tree, among other trees growing in this country.

[a] Smith. [b] Linn. ſpec. [c] Withering. [d] Scopoli.

Parkinſon enumerates ſixty-four varieties of the Pear in his Paradiſus. Moſt of theſe have been ſuperſeded by new and better ſorts, imported from France, where this fruit has had great attention paid to it: Many however of the old ſorts are ſtill to be ſeen in orchards in the country. The Catherine Pear, a ſmall red fruit, is yet common in the London markets; becauſe it comes early: but it is a poor fruit.—Rea has twenty-one ſorts for walls, thirty-five of which he calls Meat Pears, and thirteen Baking Pears: twenty-ſeven ſorts obtained out of France by Sir Thomas Hanmer, and fifty-five others, obſerved in France by the ſame gentleman, in all an hundred and fifty-one. Worlidge ſays, there are ſuppoſed to be five hundred ſorts, and that the French gardener reckons about three hundred choice ones.

Knoop, in his *Pomologia*, has an hundred and two varieties, engraved and coloured. Duhamel enumerates an hundred and nineteen, to which he ſays thirty or forty indifferent ſorts, to be found in common orchards, might be added.

Bradley (in 1724) reckons an hundred and forty ſorts, ranged according to the months in which they are fit for eating; his catalogue is from the French.

Mortimer alſo has many ſorts. The Pears eſteemed for making Perry in Worceſterſhire in his time were the Red and Green Squaſh, the John, the great Harpary, the Drake, the Mary, the Lullant; but above the reſt are eſteemed the Boſbury and Bareland Pears, the White and Red Horſe Pears, and eſpecially the Turgovian Pear, mentioned by Mr. Evelyn. In Hertfordſhire he made excellent Perry from wild Pears.—*Art of huſbandry*, 544. ed. 2. 1708.

In Worceſterſhire the Squaſh is now in much the higheſt eſteem for Perry. It is an early tender fruit, burſting when it falls ripe from the tree; whence its name. Taynton has long been famous for Squaſh Pear Perry. Other ſorts are the Oldfield, Bareland, Red Pear, Huff-cap, Sack, &c. both graſted and kernel fruits.—*Marſhall's Glouceſterſh.* 2. 256.

Miller has ſelected eighty, which are moſt eſteemed for the ſeveral purpoſes to which this fruit is applied.] Theſe varieties, ſays he, which are now cultivated in curious fruit gardens, have been accidentally obtained by ſeeds; but being generally diſtinguiſhed by the ſhape, ſize and flavour of the fruit, he gives the following diſtinctions.

1. Pyrus (*Muſk*) ſativa, fructu æſtivo parvo racemoſo odoratiſſimo. Tourn. *Petit Muſcat*, Duh. n. 1. t. 1. *i. e. Little Muſk Pear, commonly called the Supreme.* This fruit is generally produced in large cluſters; it is rather round than long, the ſtalk ſhort; and, when ripe, the ſkin is of a yellow colour; the juice is ſomewhat muſky, and, if gathered before it is too ripe, is a good Pear. This ripens the middle of july, and will continue good but for a few days.
2. Pyrus (*Chio*) ſativa, fructu æſtivo minimo odoratiſſimo. Tourn. *Poire de Chio; the Chio Pear, commonly called the little Baſtard Muſk Pear.* This is ſmaller than the former, but is in ſhape pretty much like that. The ſkin, when ripe, has a few ſtreaks of red on the ſide next the ſun, and the fruit ſeldom hangs in cluſters as the former, but in other reſpects is nearly like it.
3. Pyrus (*Citron des Carmes*, Duh. n. 7. t. 4. Haſtiveau is n. 9.) ſativa, fructu æſtivo parvo, è viridi albido. Tourn. *Poire Hâtiveau, i. e. the Haſting Pear; Poire Madeline, ou Citron des Carmes, called commonly the green Chiſel.* This is a larger Pear than either of the former, and is produced more toward the pedicel. The ſkin is thin, and of a whitiſh green colour when ripe; the fleſh is melting, and, if not too ripe, of a ſugary flavour, but is apt to be meally. This ripens in the end of july.
4. Pyrus (*Muſcadelle*) ſativa, fructu æſtivo partim ſaturatè rubente, partim flaveſcente. Tourn. *Muſcadelle Rouge; the red Muſcadelle.* It is alſo called La Belliſſime, i. e. the Faireſt or Supreme, Belliſſime d'été, or Supreme, Duh. n. 80. t. 42. This is a large early Pear, of great beauty; the ſkin is of a fine yellow colour, when ripe, beautifully ſtriped with red; the fleſh is half melting, and has a rich flavour,

if

if gathered before it be too ripe, but it is apt to be mealy. This generally produces two crops of fruit in a year; the firſt is commonly ripe about the end of july, and the ſecond ripens in ſeptember, but this late crop is ſeldom well taſted.

5. PYRUS (*Muſcat*) ſativa, fructu æſtivo parvo flaveſcente moſchato. Tourn. Petit Muſcat, i. e. *the Little Muſcat*. This is a ſmall Pear, rather round than long; the ſkin is very thin, and, when ripe, of a yelloviſh colour; the fleſh is melting, and of a rich muſky flavour, but will not keep long when ripe. This comes the end of july.

6. PYRUS (*Cuiſſe Madame*) ſativa, fructu æſtivo oblongo ferrugineo, carne tenerâ moſchatâ. Tourn. *Cuiſſe Madame*, Duh. n. 11. t. 5. *Lady's Thigh, in England commonly called Jargonelle*. This is a very long Pear, of a pyramidal ſhape, having a long foot-ſtalk; the ſkin is pretty thick, of a ruſſet green colour from the ſun, but towards the ſun it is inclined to an iron colour; the fleſh is breaking, and has a rich muſky flavour; ripe the beginning of auguſt. This is one of the beſt early ſummer Pears yet known, and is certainly what all the French gardeners call the Cuiſſe Madame, as may be eaſily obſerved by their deſcription of this Pear; but I ſuppoſe the titles of this and the Jargonelle were changed in coming to England, and they have been continued by the ſame names.

7. PYRUS (*Windſor*) ſativa, fructu oblongo, è viridi flaveſcente. *The Windſor Pear*. This is an oblong fruit, which ſwells toward the crown, but near the ſtalk is drawn toward a point; the ſkin is ſmooth, and, when ripe, of a yelloviſh green colour; the fleſh is very ſoft, and, if permitted to hang but two or three days after it is ripe, grows meally, and is good for nothing.

8. PYRUS (*Jargonelle*) ſativa, fructu æſtivo oblongo, è viridi albo. *The Jargonelle*, Duh. n. 6. *now commonly called Cuiſſe Madame*. This is certainly what the French gardeners call the Jargonelle, which, as I have before obſerved, is now in England given to another fruit much preferable to this, ſo that the two names are changed; for the Jargonelle is always placed amongſt thoſe which the French call bad fruit, and the Cuiſſe Madame is ſet down amongſt their beſt fruit, which is certainly the reverſe with us, as they are now named. This Pear is ſomewhat like the Windſor, but is not ſo ſwelling toward the crown, and is ſmaller toward the ſtalk; the ſkin is ſmooth, of a pale green colour; the fleſh is apt to be mealy if it ſtands to be ripe, but, being a plentiful bearer, is much propagated for the London markets.

9. PYRUS (*Orange Muſk*) ſativa, fructu æſtivo globoſo ſeſſili moſchato, maculis nigris conſperſo. Tourn. *Orange Muſquée*, Duh. n. 25. t. 10. *i. e. the Orange Muſk*. This is a middle-ſized Pear, of a ſhort globular form; the ſkin is of a yelloviſh colour, ſpotted with black; the fleſh is muſky, but is very apt to be a little dry and choaky. It ripens in auguſt.

10. PYRUS (*Blanquet*) ſativa, fructu æſtivo albido majori. Tourn. *Gros Blanquet*, Duh. n. 13. *i. e. Great Blanket*. This is alſo called La Muſſette d'Anjou, i. e. the Bagpipe of Anjou. It is a large Pear approaching to a round form; the ſkin is ſmooth, and of a pale green colour; the fleſh is ſoft, and full of juice, which has a rich flavour; the ſtalk is ſhort, thick, and ſpotted; the wood is ſlender, and the leaf is very much like that of the tree called the Jargonelle. This ripens the beginning of auguſt.

11. PYRUS (*Muſk Blanquet*) ſativa, fructu æſtivo albido ſaccharato odoratiſſimo. Tourn. *The Blanquette, or Muſk Blanquette*, Duh. n. 16. t. 6. *the little Blanket Pear*. This Pear is much leſs than the former, and more pinched in near the ſtalk, which is alſo ſhort, but ſlenderer than that of the former; the ſkin is ſoft, and of a pale green colour; the fleſh is tender, and full of a rich muſky juice; the wood of this tree is much ſtronger than that of the former, and the ſhoots are commonly ſhorter. This ripens the middle of auguſt.

12. PYRUS (*Long-ſtalk Blanquet*) ſativa, fructu æſtivo albido, pediculo longo donato. Tourn. *Blanquette à longue queue*, Duh. n. 15. *Long-ſtalked Blanket Pear*. This Pear is in ſhape ſomewhat like the former, but the eye is larger, and more hollow at the crown; toward the ſtalk it is ſomewhat plumper, and a little crooked; the ſkin is very ſmooth, white, and ſometimes toward the ſun is a little coloured; the fleſh is between melting and breaking, and is full of a rich ſugary juice. This ripens the middle of auguſt.

13. PYRUS (*Skinleſs*) ſativa, fructu æſtivo oblongo ruſeſcente ſaccharato. Tourn. *Poire ſans Peau*, Duh. n. 35. t. 13. *the Skinleſs Pear*. It is alſo called Fleur de Guigne, i. e. Flower of Guigne; and by ſome, Rouſſelet hâtif, i. e. the early Ruſſelet. This is a middle-ſized fruit, of a long ſhape, and a reddiſh colour, ſomewhat like the Ruſſelet; the ſkin is extremely thin; the fleſh is melting, and full of a rich ſugary juice; the ſhoots are long and ſtraight. This ripens the middle of auguſt.

14. PYRUS (*Robine*) ſativa, fructu æſtivo turbinato, carne tenera ſaccharata. *Muſcat Robine, i. e. the Muſk Robine Pear*. This is alſo called Poire à la Reine, i. e. the Queen's Pear; Poire d'Ambre, i. e. the Amber Pear; and Pucelle de Xaintonge, i. e. the Virgin of Xaintonge, *Duh. n. 3. t. 2*. This is a ſmall round Pear, of a yelloviſh colour when ripe; the fleſh is between melting and breaking. It has a rich muſky flavour, and is a great bearer; it ripens the middle of auguſt.

15. PYRUS (*Drone*) ſativa, fructu æſtivo turbinato moſchato. *Le Bourdon Muſqué*, Duh. n. 27. *the Muſk Drone Pear*. This is a middle-ſized round fruit, whoſe ſkin is of a yelloviſh colour when ripe; the fleſh is melting, and has a high muſky juice, but it muſt not hang too long on the tree, for it is ſubject to grow mealy in a ſhort time. This ripens the end of auguſt.

16. PYRUS (*Orange*) ſativa, fructu æſtivo globoſo ſeſſili, è viridi purpuraſcente ſaccharato odorato. Tourn. *Orange Rouge*, Duh. n. 26. *the red Orange Pear*. This Pear has been the moſt common of all the ſorts in France, which was occaſioned by the general eſteem it was in ſome years ſince. This is a middle-ſized round fruit, of a greeniſh colour, but the ſide next the ſun changes to a purple colour when ripe; the fleſh is melting, and the juice is ſugared with a little perfume; the eye is very hollow, and the ſtalk is ſhort. This ripens the end of auguſt.

17. PYRUS (*Caſſolette*) ſativa, fructu æſtivo oblongo minori cinereo odorato. Tourn. *Caſſolette. Friolet. Muſcat-Vert. Lechefrion*. Duh. n. 44. t. 18. This is ſo called from its being ſhaped like a perfuming-pot. It is a long fruit, in ſhape like the Cuiſſe Madame, of an Aſh colour; its fleſh is melting, and full of a perfumed juice, but it is very apt to rot in the middle as ſoon as ripe, otherwiſe it would be eſteemed an excellent Pear. It is ripe the end of auguſt.

18. PYRUS (*Orange Muſk*) ſativa, fructu æſtivo turbinato è viridi albido. *Orange Muſquée*, Duh. n. 25. t. 10. *the Muſk Orange Peer*. This is a large round Pear, in ſhape like a Bergamot; the ſkin is green, and the fleſh is melting, but it is very ſubject to rot upon the tree, which renders it not near ſo valuable as ſome others. It ripens the end of auguſt.

19. PYRUS (*Ognonet*) ſativa, fructu æſtivo globoſo è viridi purpuraſcente. Tourn. *Gros Ognonet*, Duh. n. 19. t. 8. *the Great Onion Pear*. It is alſo called Amiréroux, i. e. Brown Admired; and Roy d'Eté, i. e. King of Summer; Archiduc d'Eté, i. e. the Summer Archduke. This is a middle-ſized round Pear, of a browniſh colour next the ſun; the fleſh is melting, and the juice is paſſably good. This ripens the end of auguſt.

20. PYRUS (*Avorat*) ſativa, fructu æſtivo globoſo ſeſſili ex albido flaveſcente ſaccharato odorato. Tourn. *Robine*, Duh. n. 56. t. 27. It is alſo called Muſcat d'Aouſt, i. e. the Auguſt Muſcat; Poire d'Averat, i. e. the Averat Pear; and Poire Royale, i. e. the Royal Pear. This is a roundiſh flat Pear, in ſhape very like a Bergamot; the ſtalk is long, ſtraight, and a little ſpotted, and the eye is a little hollowed; the ſkin is ſmooth, and of a whitiſh yellow colour; the fleſh is breaking, but not hard, and its juice is richly

ſugared and perfumed. It is a great bearer, and is eſteemed one of the beſt ſummer Pears yet known; it ripens the end of auguſt.

21. Pyrus (*Roſe*) ſativa, fructu æſtivo globoſo ſeſſili odorato. Tourn. *Poire de roſe*, Duh. n. 57. *the Roſe-Pear*; *and Epine-roſe, i. e. the Thorny Roſe.* This is a ſhort round fruit, ſhaped like the great Onion Pear, but much larger; of a yelloviſh green colour; but a little inclining to red on the ſide next the ſun; the ſtalk is very long and ſlender; the fleſh is breaking, and the juice is muſky: this ripens the end of auguſt. The ſhoots and the leaves of this tree are large.

22. Pyrus (*Pouchet*) ſativa, fructu æſtivo globoſo albido ſaccharato. Tourn. *Poire du Pouchet.* This is a large, round, whitiſh Pear, ſhaped ſomewhat like the Beſideri; the fleſh is ſoft and tender, and the juice is ſugary; this ripens the end of auguſt.

23. Pyrus (*Parfumé*) ſativa, fructu æſtivo turbinato ſeſſile ſaturatiùs rubente punctato. Tourn. *Poire Parfumé, i. e. the perfumed Pear.* This is a middle-ſized round fruit, whoſe ſkin is ſomewhat thick and tough, and of a deep red colour, ſpotted with brown; the fleſh is melting, but dry, and has a perfumed flavour. This ripens the end of auguſt.

24. Pyrus (*Boncrétien*) ſativa, fructu æſtivo oblongo magno, partim rubro, partim albido odorato. Tourn. *Boncrétien d'Eté*, Duh. n. 40. t. 47. f. 4. *the Summer Boncrétien.* This is a large oblong fruit, whoſe ſkin is ſmooth and thin; the ſide next the ſun is of a beautiful red colour, but the other ſide is of a whitiſh green; the fleſh is between breaking and tender, and is very full of juice, which is of a rich perfumed flavour. It ripens the beginning of ſeptember.

25. Pyrus (*Salviati*) ſativa, fructu æſtivo globoſo, ex rubro albidoque flaveſcente ſaccharato odorato. Tourn. *Salviati*, Duh. n. 21. t. 9. This Pear is pretty large, round, and flat, very much like the Beſideri in ſhape, but not in colour; the ſtalk is very long and ſlender, and the fruit is a little hollowed both at the eye and ſtalk; the colour is red and yellow next the ſun, but on the other ſide is whiriſh; the ſkin is rough, the fleſh is tender, but a little ſoft, and has no core; the juice is ſugary and perfumed, ſomewhat like the Robine, but is not near ſo moiſt. This ripens the beginning of ſeptember.

26. Pyrus (*Caillet-roſat*) ſativa, fructu æſtivo globoſo ſeſſili ruſeſcente odorato. Tourn. *Caillot-roſat*, Duh. p. 177. *the Roſe-water Pear.* This is a large round Pear, ſomewhat like the Meſſire Jean, but rounder; the ſtalk is very ſhort, and the fruit is hollowed like an Apple, where the ſtalk is produced; the ſkin is rough, and of a brown colour; the fleſh is breaking, and the juice is very ſweet. This ripens the middle of ſeptember.

27. Pyrus (*Choak-Pear*) ſativa, fructu æſtivo longo, acerbitate ſtrangulationem minitante. Tourn. *Poire d'Etrangillon, the choaky Pear.* The fleſh is red. This is ſeldom preſerved in gardens, ſo there needs no deſcription of it.

28. Pyrus (*Rouſſelet*) ſativa, fructu æſtivo oblongo è ferrugineo rubente, nonnunquam maculato. *Poire du Rouſſelet, the Ruſſelet Pear.* Gros Rouſſelet. Roy d'eté. Duh. n. 34. t. 12. This is a large oblong Pear; the ſkin is brown, and of a dark red colour next the ſun; the fleſh is ſoft and tender, without much core; the juice is agreeably perfumed, if gathered before it be too ripe. This produces larger fruit on an eſpalier than on ſtandard trees: it ripens the middle of ſeptember.

29. Pyrus (*Prince's Pear*) ſativa, fructu æſtivo ſubrotundo, partim rubro, partim flaveſcente, odorato. *Poire de Prince, the Prince's Pear.* This is a ſmall roundiſh Pear, of a bright red colour next the ſun, but a yelloviſh colour on the oppoſite ſide; the fleſh is between breaking and melting; the juice is very high-flavoured: it is a great bearer. This ripens the middle of ſeptember, but will keep a fortnight good, which is what few ſummer-fruits will do.

30. Pyrus (*Moüille-bouche*) ſativa, fructu æſtivo globoſo viridi, in ore liqueſcente. *Gros Moüille-bouche, i. e. the great Mouthwater Pear.* This is a large round Pear with a ſmooth green ſkin; the ſtalk is ſhort and thick; the fleſh is melting, and full of juice, if gathered before it be too ripe, otherwiſe it is apt to grow mealy. This ripens the middle of ſeptember.

31. Pyrus (*Bergamotte d'Eté*) ſativa, fructu æſtivo rotundo ſeſſili ſaccharato, è viridi flaveſcente. *Bergamotte d'Eté*, Duh. n. 45. *Summer Bergamot.* This is by ſome called the Hamden's Bergamot. It is a pretty large, round, flat Pear, of a greeniſh yellow colour, and hollowed a little at both ends like an Apple; the fleſh is melting, and the juice is highly perfumed. This ripens the middle of ſeptember.

32. Pyrus (*Bergamot Autumn*) ſativa, fructu autumnali ſeſſili ſaccharato odorato è viridi flaveſcente, in ore liqueſcente. Tourn. *Bergamotte d'Automne*, Duh. n. 48. t. 21. *the Autumn Bergamot.* This is a ſmaller Pear than the former, but is nearly of the ſame ſhape; the ſkin is of a yelloviſh green, but changes to a faint red on the ſide next the ſun; the fleſh is melting, and its juice is richly perfumed. It is a great bearer, ripens the end of ſeptember, and is one of the beſt Pears of the ſeaſon.

33. Pyrus (*Swiſs Bergamot*) ſativa, fructu autumnali turbinato viridi, ſtriis ſanguineis diſtincta. Tourn. *Bergamotte Suiſſe*, Duh. n. 47. t. 20. *the Swiſs Bergamot.* This Pear is ſomewhat rounder than either of the former; the ſkin is tough, and of a greeniſh colour, ſtriped with red: the fleſh is melting, and full of juice, but is not ſo richly perfumed as either of the former. This ripens the end of ſeptember.

34. Pyrus (*Beurré Rouge*) ſativa, fructu autumnali ſuaviſſimo, in ore liqueſcente. Tourn. *Beurré Rouge*, Duh. n. 75, 76. t. 38, 39. *the red Butter Pear.* It is called l'Amboiſe, and in Normandy Iſambert; as alſo Beurré gris, i. e. the gray Butter; and Beurré vert, i. e. the green Butter Pear. All theſe different names of Beurrés have been occaſioned by the difference of the colours of the ſame ſort of Pear, which is either owing to the different expoſure where they grew, or from the ſtock, thoſe upon the free ſtocks being commonly of a browner colour than thoſe which are upon Quince ſtocks, whence ſome perſons have ſuppoſed them to be different fruits, though in reality they are the ſame. This is a large long fruit, for the moſt part of a brown colour. The fleſh is very melting, and full of a rich ſugary juice. It ripens the beginning of october, and, when gathered from the tree, is one of the very beſt ſort of Pears we have.

35. Pyrus (*Doyenne*) ſativa, fructu autumnali turbinato ſeſſili flaveſcente, et in ore liqueſcente. Tourn. *Doyenné*, Duh. n. 81. t. 43. *the Dean's Pear.* It is alſo called by all the following names; Saint Michel, i. e. Saint Michael; Beurré blanc d'Automne, i. e. the white Autumn Butter Pear; Poire de Neige, i. e. the Snow Pear; Bonne Ente, i. e. a good Graft; the Carliſle, and Valentia. This is a large fruit, in ſhape ſomewhat like the gray Beurré, but ſhorter and rounder; the ſkin is ſmooth, and, when ripe, changes to a yelloviſh colour; the fleſh is melting, and full of juice, which is very cold, but it will not keep good much more than a week after it is gathered, being very ſubject to grow mealy; it is a very indifferent fruit. This is a great bearer, and ripens the beginning of october.

36. Pyrus (*Verte-longue*) ſativa, fructu autumnali longo viridique odorato, in ore liqueſcente. Tourn. *La Verte-longue*, Duh. n. 74. t. 73. *the long green Pear.* It is alſo called Moüille bouche d'Automne, i. e. the Autumn Mouthwater Pear. This is a long fruit, which is very green when ripe; the fleſh is melting, and very full of juice, which, if it grows upon a dry warm ſoil, and a free ſtock, is very ſugary, otherwiſe it is but a very indifferent Pear. It ripens the middle of october, but in ſome years will keep till december.

37. Pyrus (*Meſſire Jean*) ſativa, fructu autumnali tuberoſo ſeſſili ſaccharato, carne durâ. Tourn. *Meſſire Jean blanc & gris*, Duh. n. 55. t. 26. *the white and gray Monſieur John.* Theſe, although made two ſorts of fruit by many perſons, are indubitably the ſame; the difference of their colour proceeding from the different ſoils and ſituations where they grow, or the ſtocks on which they are grafted. This Pear, when

grafted

grafted on a free ſtock, and planted on a middling ſoil, neither too wet nor over dry, is an excellent autumn Pear; but when it is grafted on a Quince ſtock, it is very apt to be ſtony; or if planted on a very dry ſoil, is very apt to be ſmall and good for little, unleſs the trees are watered in dry ſeaſons, which has rendered it leſs eſteemed by ſome perſons, who have not conſidered the cauſe of their hardneſs; for when it is rightly managed, there are not many Pears in the ſame ſeaſon to be compared with it. This is a large roundiſh fruit, the ſkin is rough, and commonly of a brown colour; the fleſh is breaking, and full of a rich ſugared juice. It ripens the end of october, and will continue good near a month.

38. Pyrus (*Muſcat fleuri*) ſativa, fructu autumnali globoſo ferrugineo, carne tenerâ ſapidiſſimâ. Tourn. *Muſcat fleuri*, Duh. n. 4. *the flowered Muſcat*. It is alſo called Muſcat à longue queüe d'Automne, i. e. the long-ſtalked Muſcat of the Autumn. This is an excellent Pear, of a middling ſize, and round; the ſkin is of a dark red colour; the fleſh is very tender, and of a delicate flavour. It ripens the end of october.

39. Pyrus (*Poire de Vigne*) ſativa, fructu autumnali globoſo ferrugineo, carne viſcidâ. Tourn. *Poir de Vigne*, Vigne. Demoiſelle. Duh. n. 110. t. 58. f. 2. *the Vine Pear*. This is a round fruit, of a middling ſize; the ſkin of a dark red colour; the fleſh is very melting, and full of a clammy juice; the ſtalk is very long and ſlender. The fruit ſhould be gathered before it be full ripe, otherwiſe it grows meally and ſoon rots. It ripens the end of october.

40. Pyrus (*Rouſſeline*) ſativa, fructu autumnali oblongo, dilutè ruſeſcente, ſaccharato, odoratiſſimo. Tourn. *Poire Rouſſeline*, Duh. n. 37. t. 15. *the Rouſſeline Pear*. It is alſo called in Touraine, Le Muſcat à longue queüe de la fin d'automne, i. e. the long-ſtalked Muſcat of the end of autumn. This is by ſome Engliſh gardeners called the Brute-bonne, but that is a very different fruit from this. It is ſhaped ſomewhat like the Rouſſelet, but the ſkin of this is ſmooth, and of a greeniſh yellow from the ſun, but the ſide next the ſun is of a deep red colour, with ſome ſpots of gray; the fleſh is very tender and delicate; the juice is very ſweet, with an agreeable perfume. It ripens the middle of october, but muſt not be long kept, leſt it rot in the middle.

41. Pyrus (*Pendar*) ſativa, fructu autumnali oblongo majori cinereo. Tourn. *Poire Pendar, i. e. the Knave's Pear*. This is very like the Caſſolette Pear, but is ſomewhat larger; the fleſh is fine and tender; the juice is very much ſugared. It ripens the end of october.

42. Pyrus (*Sucré vert*) ſativa, fructu autumnali turbinato tuberoſo viridi ſaccharato, in ore liqueſcente. Tourn. *Sucré vert*, Duh. n. 68. t. 34. *the green Sugar Pear*. This Pear is ſhaped like the Winter Thorn, but is ſmaller; the ſkin is very ſmooth and green; the fleſh is very buttery; the juice is ſugared, and of an agreeable flavour; but it is ſometimes ſubject to be ſtony in the middle, eſpecially if grafted on a Quince ſtock.

43. Pyrus (*Marquiſe*) ſativa, fructu autumnali tuberoſo ſeſſili, è viridi flaveſcente, maculis nigris conſperſo, carne tenerâ ſaccharatâ. Tourn. *La Marquiſe*, Duh. n. 93. t. 49. *the Marchioneſs's Pear*. This is often of two different ſhapes, according to the nature of the ſoil where they are planted; for when the ſoil is dry, the fruit very much reſembles a fine Blanquet; but when the ſoil is very rich and moiſt, it grows much larger. It is a well-ſhaped Pear, flat at the top; the eye is ſmall and hollowed; the ſkin is of a greeniſh yellow, a little inclining to red on the ſide next the ſun. If this Pear does not change yellow in ripening it is ſeldom good; but if it does, the fleſh will be tender and delicate, very full of juice, which is ſugared. It ripens the beginning of november.

44. Pyrus (*Chat-brulé*) ſativa, fructu autumnali, oblongo, partim albido, partim ruſeſcente. *The Chat-brulé*, Duh. n. 116. *the Burnt Cat*. It is alſo called Pucelle de Xaintogne, i. e. the Virgin of Xaintogne. This is a ſmall oblong Pear, ſhaped much like the Martin Sec, but differs from it in colour, this being of a pale colour on one ſide, but of a dark brown on the other; the ſkin is ſmooth; the fleſh is tender, but dry, and, if kept a ſhort time, is apt to grow meally. It is in eating the beginning of november.

45. Pyrus (*Beſidéri*) ſativa, fructu autumnali globoſo ſeſſili, ex albido flaveſcente. *Le Bezi d'Hery*, Duh. n. 23. It is ſo called from Heri, which is a foreſt in Bretagne, between Rennes and Nantes, where this Pear was found. This is a middle-ſized round Pear, of a pale green, inclining to a yelloviſh colour; the ſtalk is very long and ſlender; the fleſh is dry, and but very indifferent for eating, but it bakes well. It ripens the middle of november.

46. Pyrus (*Craſane*) ſativa, fructu brumali ſeſſili, è viridi flaveſcente, maculato, utrinque umbilicato, in ore liqueſcente. Tourn. *The Craſanne, or Bergamotte Craſanne*, Duh. n. 49. t. 22. It is alſo called Buerré Plat, i. e. the flat Butter Pear. This is a middle-ſized Pear, hollowed at the crown like an Apple; the ſtalk is very long and crooked; the ſkin is rough, of a greeniſh yellow colour when ripe, covered over with a ruſſet coat; the fleſh is extremely tender and buttery, and is full of a rich ſugary juice, and is the very beſt Pear of the ſeaſon. This is in eating the middle of november.

47. Pyrus (*Dauphine*) ſativa, fructu brumali turbinato ſeſſili flaveſcente ſaccharato odorato, in ore liqueſcente. Tourn. *Lanſac ou la Dauphine*, Duh. n. 109. t. 57. *the Lanſac or Dauphine Pear*. This Pear is commonly about the ſize of a Bergamot, of a roundiſh figure, flat towards the head, but a little produced towards the ſtalk; the ſkin is ſmooth, and of a yelloviſh green colour; the fleſh is yellow, tender, and melting; the juice is ſugared, and a little perfumed; the eye is very large, as is alſo the flower, and the ſtalk is long and ſtraight. When this Pear is upon a free ſtock, and planted on a good ſoil, it is one of the beſt fruits of the ſeaſon; but when it is on a Quince ſtock, or upon a very dry ſoil, the fruit will be ſmall, ſtony, and worth little. It ripens the end of november.

48. Pyrus (*Martin Sec*) ſativa, fructu brumali oblongo, partim intenſè, partim dilute ferrugineo, ſaccharato, odorato. Tourn. *Martin Sec*, Duh. n. 36. t. 14. *the Dry Martin*. This is ſometimes called the Dry Martin of Champagne, to diſtinguiſh it from another Dry Martin of Burgundy. This Pear is almoſt like the Rouſſelet in ſhape and colour, which has occaſioned ſome perſons to give it the name of Winter Ruſſelet. It is an oblong Pear, whoſe ſkin is of a deep ruſſet colour on one ſide, but the other ſide is inclining to a red; the fleſh is breaking and fine; the juice is ſugared, with a little perfume, and if grafted on a free ſtock, is an excellent Pear, but if it be on a Quince ſtock, it is very apt to be ſtony. It is in eating the end of november, but if permitted to hang the full time on the tree, will keep good two months.

49. Pyrus (*Bigarrade*) ſativa, fructu brumali magno ſeſſili, è cinereo flaveſcente. Tourn. *La Villaine d'Anjou*. It is alſo called Poire Tulipée, i. e. the Tulip Pear, and Bigarrade, i. e. the Great Orange. This is a large round Pear, with a very long ſlender ſtalk; the ſkin is of a pale yellow colour; the fleſh is breaking, but not very full of juice. This is in eating the end of november.

50. Pyrus (*Poire de gros queüe*) ſativa, fructu brumali flaveſcente odoratiſſimo, pediculo craſſiori. Tourn. *Poire de gros queüe, i. e. the large ſtalked Pear*. This is a large roundiſh Pear, with a yellow ſkin; the ſtalk is very thick, from whence it had the name; the fleſh is breaking and dry, and has a very muſky flavour; but it is apt to be ſtony, eſpecially if it be planted in a dry ſoil, or grafted on a Quince-ſtock, as are moſt of the perfumed Pears.

51. Pyrus (*Amadate*) ſativa, fructu brumali turbinato ruſeſcente odorato. *L'Amadote, i. e. the Amadot Pear*. This is a middle-ſized Pear, ſomewhat long, but flat at the top; the ſkin is generally rough, and of a ruſſet colour; the fleſh is dry and high-flavoured, if grafted on a free ſtock. The wood of this tree is

generally thorny, and is eſteemed the beſt ſort of Pear for ſtocks to graft the melting Pears upon, becauſe it gives them ſome of their fine muſky flavour. It is in eating the beginning of december, but will keep good ſix weeks.

52. Pyrus (*Bouvar*) ſativa, fructu brumali, globoſo, dilutè virente, tuberoſo, punctato, in ore liqueſcente. Tourn. *Petit Oin, i. e. Little Lard Pear.* It is alſo called Bouvar and Rouſette d'Anjou, i. e. the Ruſſet of Anjou; and Amadont, and Merveille d'Hyver, i. e. the Wonder of the Winter. This Pear is of the ſize and ſhape of the Ambret or Leſchaſſerie, but the ſkin is of a clear green colour, and a little ſpotted; the ſtalk is pretty long and ſlender; the eye is large, and deeply hollowed; the fleſh is extremely fine, and melting; the juice is much ſugared, and has an agreeable muſky flavour. It is in eating the middle of December, and is eſteemed one of the beſt fruits in that ſeaſon. This is better on a free ſtock than upon the Quince.

53. Pyrus (*Louiſebonne*) ſativa, fructu brumali, longo, è viridi albicante, in ore liqueſcente. Tourn. *Louiſebonne*, Duh. 97. t. 53. This Pear is ſhaped ſomewhat like the St. Germain, or the Autumn Vertelongue, but is not quite ſo much pointed; the ſtalk is very ſhort, fleſhy, and ſomewhat bent; the eye and the flower are ſmall; the ſkin is very ſmooth; the colour is green, inclining to a pale colour when ripe; the fleſh is extremely tender and full of juice, which is very ſweet, eſpecially when it grows upon a dry ſoil, otherwiſe it is apt to be very large and ill taſted. It is in eating the beginning of december.

54. Pyrus (*Colmar*) ſativa, fructu brumali, tuberoſo, è viridi flaveſcente, punctato, ſaccharato. Tourn. *Poire de Colmar, i. e. the Colmar Pear.* It is alſo called Poire Manne, the Manna Pear, and Bergamotte tardive, the late Bergamot. Colmart Poire Manne. Duh. n. 94. t. 50. This Pear is ſomewhat like a Boncrêtien in ſhape, but the head is flat; the eye is large, and deeply hollowed; the middle is larger than the head, and is ſloped toward the ſtalk, which is ſhort, large, and a little bent; the ſkin is green, with a few yellowiſh ſpots, but is ſometimes a little coloured on the ſide next the ſun; the fleſh is very tender, and the juice is greatly ſugared. It is in eating the latter end of december, but will often keep good till the end of january, and is eſteemed one of the beſt fruits of that ſeaſon.

55. Pyrus (*L'Eſchaſſerie*) ſativa, fructu brumali, globoſo, citriformi, flaveſcente, punctato, in ore liqueſcente, ſaccharato, odoratiſſimo. Tourn. *L'Eſchaſſerie.* It is alſo called Vertelongue d'Hyver, i. e. the Winter long green Pear, and Beſidéri Landri, i. e. the Landry Wilding. Echaſſery. Bezi de Chaſſery, Duh. n. 66. t. 32. This Pear is ſhaped like a Citron; the ſkin is ſmooth, and of a green colour, with ſome ſpots while it hangs on the tree, but as it ripens it becomes of a yellowiſh colour; the ſtalk is ſtraight and long; the eye is ſmall, and not hollowed; the fleſh is melting, and buttery; the juice is ſugared, with a little perfume. It is in eating the latter end of december.

56. Pyrus (*Virgoulouſe*) ſativa, fructu brumali longo, è viridi flaveſcente, in ore liqueſcente, ſaccharato. Tourn. *Le Virgoulé, or La Virgouleuſe*, Duh. n. 95. t. 51. It is alſo called Bujaleuf, and Chambrette; and Poire de Glace, i. e. the Ice Pear in Gaſcoigne; but it is called Virgoule, from a village of that name in the neighbourhood of St. Leonard in Limouſin, where it was raiſed and ſent to Paris by the Marquis of Chambret. This Pear is large, long, and of a green colour, inclining to yellow as it ripens; the ſtalk is ſhort, fleſhy, and a little bent; the eye is of a middling ſize, and a little hollowed; the ſkin is very ſmooth, and ſometimes a little coloured towards the ſun; the fleſh is melting, and full of a rich juice. It is in eating the latter end of december, and will continue good till the end of january, and is eſteemed one of the beſt fruits of the ſeaſon; but the tree is very apt to produce vigorous ſhoots, and the bloſſoms being generally produced at the extreme part of the ſhoot, when they are ſhortened, the fruit will be entirely cut away, which is the reaſon it is condemned as a bad bearer; but when it is grafted on a free ſtock, it ought to be allowed at leaſt forty feet to ſpread; and if upon a Quince ſtock, it ſhould be allowed upwards of thirty feet, and the branches trained in againſt the eſpalier or wall, at full length, in a horizontal poſition, as they are produced. Where this tree is thus treated, it will bear very plentifully, and the fruit will be good.

57. Pyrus (*Ambrette*) ſativa ſpinoſa, fructu globoſo, ſeſſili, ferrugineo, in ore liqueſcente, ſaccharato, odoratiſſimo. Tourn. *Ambrette*, Duh. n. 65. t. 31. This is ſo called from its muſky flavour, which reſembles the ſmell of the Sweet Sultan Flower, which is called Ambrette in France. This Pear is like the Leſchaſſerie in ſhape, but is of a ruſſet colour; the eye is larger, and more hollowed; the fleſh is melting, and the juice is richly ſugared and perfumed; the ſeeds are large and black, and the cells in which they are lodged are very large; the wood is very thorny, eſpecially when grafted on free ſtocks. The fruit is in eating the latter end of december, and continues good till the latter end of january, and is eſteemed a very good fruit by moſt people.

58. Pyrus (*Epine d'Hyver*) ſativa, fructu brumali, magno, pyramidato, albido, in ore liqueſcente, ſaccharato, odorato. Tourn. *Epine d'Hiver*, Duh. n. 64. t. 44. f. 3. *Winter-thorn Pear.* This is a large fine Pear, nearly of a pyramidal figure; the ſkin is ſmooth, and of a pale green colour, inclining to yellow as it ripens; the ſtalk is ſhort and ſlender; the fleſh is melting and buttery; the juice is very ſweet, and in a dry ſeaſon, is highly perfumed; but when it is planted on a moiſt ſoil, or the ſeaſon proves wet, it is very inſipid, ſo that it ſhould never be planted on a ſtrong ſoil. It ripens the end of december, and will continue good two months.

59. Pyrus (*Saint Germain*) ſativa, fructu brumali longo, è viridi flaveſcente, in ore liqueſcente. Tourn. *Saint Germain*, Duh. n. 96. t. 52. *the St. Germain Pear.* It is alſo called Inconnue la Fare, i. e. the Unknown of La Fare; it being firſt diſcovered upon the banks of a river which is called by that name, in the pariſh of St. Germain. This is a large long Pear, of a yellowiſh green colour when ripe; the fleſh is melting, and very full of juice, which in a dry ſeaſon, or if planted on a warm dry ſoil, is very ſweet; but when it is planted on a moiſt ſoil, the juice is very apt to be harſh and auſtere, which renders it leſs eſteemed by ſome perſons, though in general it is greatly valued. This is in eating from the end of december till february.

60. Pyrus (*Saint Auſtin*) ſativa, fructu brumali tuberoſo ſubacido flaveſcente punctato. Tourn. Saint Auguſtin, Duh. n. 99. t. 58. f. 3. This is about the ſize of a middling Virgoulé Pear, but is ſomewhat ſhorter and ſlenderer near the ſtalk; the ſkin is of a fine Citron colour, ſpotted with red on the ſide next the ſun; the fleſh is tender, but not buttery, and is pretty full of juice, which is often a little ſharp, and to ſome perſons is diſagreeable, but others value it on that account. This is in eating in december, and will continue good two months.

61. Pyrus (*Boncrêtien d'Eſpagne*) ſativa, fructu brumali pyramidato, partim purpureo, punctis nigris conſperſo, flaveſcente. Tourn. *Boncrêtien d'Eſpagne*, Duh. n. 89. t. 46. *the Spaniſh Boncrêtien.* This is a large Pear, of a pyramidal form, of a fine red or purple colour on the ſide next the ſun, and full of ſmall black ſpots; the other ſide is of a pale yellow colour, the fleſh is breaking, and when it is on a light rich ſoil, and grafted on a free ſtock, its juice is very ſweet. It ripens in the end of december, and will continue good a month or ſix weeks. If this be grafted on a Quince ſtock, it is very apt to be dry and ſtony. This is a very good fruit for baking.

62. Pyrus (*Poire de Livre*) ſativa, fructu brumali, magno, oblongo, turbinato, ferrugineo, utrinque umbilicato. Tourn. *Poire de Livre*, Duh. n. 104. *the Pound Pear.* It is alſo called Gros Ratteau Gris, the gray rake Pear; and Poire d'Amour. In England

this

this is called Parkinſon's Warden, or the black Pear of Worceſter. This is a very large Pear, and commonly weighs a pound or more; the ſkin is rough, and of an obſcure red colour on the ſide next the ſun, but ſomewhat paler on the other ſide; the ſtalk is very ſhort, and the eye is greatly hollowed. This is not fit for eating, but bakes or ſtews exceeding well, and is in ſeaſon from December to march.

63. PYRUS (*Beſi de Caſſoy*) ſativa, fructu brumali parvo flaveſcente, maculis rubris conſperſo. Tourn. *Beſi de Caſſoy, i. e. the Wilding of Caſſoy*, a foreſt in Bretagne, where it was diſcovered, and paſſes under the name of Rouſſet d'Anjou. It is alſo called Petit Beurré d'Hyver, i. e. Small Winter Butter Pear. Bezy de Caiſſoy; or, Rouſſette d'Anjou, Duh. n. 59. t. 29. This is a ſmall oblong Pear, of a yelloviſh colour, ſpotted with red; the fleſh is melting, and the juice is very rich. It is in eating in december and january. This is a prodigious bearer, and commonly produces its fruit in large cluſters, provided it be not too much pruned; for it generally produces its bloſſom-buds at the extremity of its ſhoots, which if ſhortened, the fruit would be cut away. There was a tree of this kind in the gardens of Camden-houſe near Kenſington, which generally produced a great quantity of fruit.

64. PYRUS (*Martin-ſire*) ſativa, fructu brumali turbinato inæquali, ventre tumido, partim purpureo, partim flaveſcente. Tourn. *Ronville*. It is alſo called Hocrenaille and Martin-ſire, i. e. the Lord Martin Pear. Martin-ſire Ronville, Duh. n. 30. t. 19. f. 5. This Pear is about the ſize and ſhape of a large Rouſſelet; the eye is of a middling ſize, and hollowed a little; the middle of the Pear is generally ſwelled more on one ſide than on the other, but is equally extended towards the ſtalk; the ſkin is very ſmooth and ſoft, and is of a lively red colour next the ſun, but on the other ſide it changes yellow as it ripens. The fleſh is breaking and full of juice, which is very ſweet and a little perfumed; but if grafted on a Quince ſtock, is very apt to be ſmall and ſtony.

65. PYRUS (*Citron d'Hyver*) ſativa, fructu brumali citriformi flaveſcente duro moſchato odoratiſſimo. Tourn. *Citron d'Hyver, i. e. the Winter Citron Pear*. It is alſo called the Muſk Orange Pear, in ſome places. This is a pretty large Pear, in ſhape and colour very like an Orange or Citron, from whence it had its name. The fleſh is hard and dry, and very ſubject to be ſtony, for which reaſons it is not valued as an eating Pear, but will bake very well. It is in ſeaſon from december to march.

66. PYRUS (*Rouſſelet d'Hiver*) ſativa, fructu brumali oblongo, è viridi flaveſcente, ſaccharato, ſaporis auſteri. Tourn. *Rouſſelet d'Hiver*, Duh. n. 31. t. 19. f. 2. *the Winter Ruſſelet*. This is by ſome ſuppoſed to be the ſame Pear as is called the Dry Martin, but it is very different from that in ſeveral particulars. The colour of this is a greeniſh yellow, inclining to brown; the ſtalk is long and ſlender, and the fleſh is buttery and melting, and generally full of juice, which is very ſweet, but the ſkin is apt to contain an auſtere juice, ſo that if it be not pared, it is apt to be diſagreeable to many perſons palates. It is in eating in january and february.

67. PYRUS (*Portail*) ſativa Pictavienſis, fructu brumali globoſo ſeſſili ſaccharato odorato. Tourn. *Poir Portail*. This Pear was diſcovered in the province of Poictou, where it was ſo much eſteemed, that they preferred it to moſt other fruit, though in the opinion of the moſt curious judges, it does not deſerve the great character which is given to it; for it rarely happens that it proves good for eating, being generally dry, ſtony, and hard, unleſs in extraordinary ſeaſons, and upon a very good ſoil. This muſt always be grafted on a free ſtock, and ſhould be planted on a light rich ſoil; and in very dry ſeaſons the trees ſhould be watered, otherwiſe the fruit will be ſtony. It is in ſeaſon from january to march, and bakes well.

68. PYRUS (*France-real*) ſativa, fructu brumali magno globoſo flaveſcente, punctis rufis conſperſo. Tourn. *France real*, Duh. n. 6. It is alſo called Fin-or d'Hyver, i. e. the Golden End of Winter. This is a very large Pear, almoſt of a globular figure; the ſkin is yellow, ſpotted with red; and the ſtalk is ſhort. The fleſh of this Pear is dry, and very apt to be ſtony, but it bakes exceeding well, and continues good from january till march.

69. PYRUS (*Eaſter Bergamot*) ſativa fructu, brumali turbinato ſeſſili ſubacido flaveſcente, punctis aſperioribus conſperſo. Tourn. *Bergamotte Bugi*. It is alſo called Bergamotte de Pâque, the Eaſter Bergamot. Duh. n. 52. t. 24. It is a large Pear, almoſt round, but is a little produced in length towards the ſtalk; the eye is flat and the ſkin is green, having many rough protuberances like ſpots diſperſed all over, but, as it ripens, becomes yelloviſh; the fleſh is breaking, and in a good ſeaſon the juice is ſweet; but it muſt have a free ſtock, a ſouth-eaſt wall, and a good ſoil, otherwiſe it is apt to be ſtony and auſtere. It is in eating from february till april.

70. PYRUS (*Muſcat of Germany*) Muſcat d'Alleman, Duh. n. 72. t. 36. This is an excellent Pear, more long than round, of the ſhape of the Winter-royal, but is leſs toward the eye, and is more ruſſet, and of a red colour next the ſun; it is buttery, melting, and a little muſky. This is in eating in march, april, and ſometimes in may, if it is well preſerved.

71. PYRUS *Bergamotte de Hollande*, or *d'Aiençon*. Amoſelle. Duh. n. 53. t. 25. It is large and round, of the ſhape of the ordinary Bergamot. The colour is greeniſh, the fleſh is half buttery and tender, the juice is highly flavoured. This is a very good Pear, and will keep till april.

72. PYRUS (*Naples*) Duh. n. 107. t. 56. This is a pretty large, long, greeniſh Pear; the fleſh is half breaking; the juice is ſweet, and a little vinous. It is in eating in march. I am in doubt whether this Pear is not in ſome places taken for a Saint Germain, for there is a Pear in ſome gardens, very like the Saint Germain, which will keep till april, and this Pear agrees with the characters of that. It is called in England the Eaſter-St. Germain.

73. PYRUS (*Boncrêtien d'Hiver*) ſativa, fructu brumali magno pyramidato, è flavo nonnihil rubente. Tourn. *Boncrêtien d'Hyver*, Duh. n. 87. t. 45. *the Winter Boncrêtien Pear*. This Pear is very large and long, of a pyramidal figure; the ſkin is of a yelloviſh colour, but the ſide next the ſun inclines to a ſoft red; the fleſh is tender and breaking, and is very full of rich ſugared juice. This is eſteemed in France one of the beſt winter Pears, but in England it is ſeldom ſo good; though I am fully ſatisfied, if it were grafted on a free ſtock, and planted in a good ſoil, againſt a wall expoſed to the ſouth-eaſt, and the branches trained at full length, it might be rendered more acceptable than it is at preſent in England.

74. PYRUS (*Catillac*) ſativa, fructu brumali magno, cydoniæ facie, partim flavo, partim purpureo. Tourn. *Catillac*, Duh. n. 102. t. 58. f. 4. This is a large Pear, ſhaped ſomewhat like a Quince; the ſkin is for the moſt part of a yellow colour, but changes to a deep red on the ſide next the ſun; the fleſh is hard, and the juice auſtere, but it is a very good fruit for baking, and being a plentiful bearer, deſerves a place in every good collection of fruit. It will be good from Chriſtmas to april, or longer.

75. PYRUS (*Paſtorale*) ſativa, fructu brumali oblongo flaveſcente, punctis rubris conſperſo. *La Paſtorale, Muſette d'automne*. Duh. n. 100. t. 55. This Pear is of the ſize and ſhape of a fine Rouſſelet; the ſtalk is ſhort and crooked; the ſkin is ſomewhat rough, of a yelloviſh colour, ſpotted with red; the fleſh is tender and buttery, and when it grows on a dry ſoil, the juice is very ſweet; but on a wet ſoil, or in moiſt years, it is ſubject to have an auſtere taſte. This Pear is in eating in february and march.

76. PYRUS (*Double Fleur*) ſativa, fructu brumali ſeſſili, partim flaveſcente, partim purpuraſcente. Tourn. *La Double Fleur*, Duh. n. 58. t. 28. *the double-flowering Pear*. This is ſo called, becauſe the flowers have a double range of petals or leaves. It is a large ſhort Pear; the ſtalk is long and ſtraight; the ſkin

is very ſmooth, and of a yelloviſh colour, but the ſide next the ſun is commonly of a fine red or purple colour. This is by ſome eſteemed for eating, but it is generally too auſtere in this country for that purpoſe. It is the beſt Pear in the world for baking or compoſts. It is good from February to may.

77. Pyrus (*Saint Martial*) ſativa, fructu brumali oblongo, partim flaveſcente, partim purpuraſcente. *Saint Martial.* It is alſo called in ſome places Poire Angelique, i. e. the Angelic Pear; and in the ſouth of France, Poire douce. Angelique de Rome. Duh. n. 108. This Pear is oblong, in ſhape like the Boncrétien, but not ſo large, and a little flatter at the crown; it has a very long ſtalk; the ſkin is ſmooth and yelloviſh, but on the ſide next the ſun it turns to a purpliſh colour; the fleſh is tender and buttery, and the juice is very ſweet. This is in eating in february and march.

78. Pyrus (*Beſi Chaumontelle*) ſativa, fructu brumali oblongo, partim albido, partim purpureo odorato, ſaccharato. *La Poire de Chaumontelle, or Bezi de Chaumontelle, or Beurre d'hiver.* Duh. n. 78. t. 40. This Pear is in ſhape ſomewhat like the Autumn Beurré, but is flatter at the crown; the ſkin is a little rough, of a pale green colour, but turns to a purpliſh colour next the ſun; the fleſh is melting; the juice is very rich, and a little perfumed. It is in eating from november to january, and is eſteemed by ſome as the beſt late Pear yet known.

79. Pyrus (*Carmelite*) ſativa, fructu brumali globoſo ſeſſili cinereo maculis amplis obſcurioribus conſperſo. Tourn. *Carmelite.* This is a middle-ſized Pear, of a roundiſh form; the ſkin is of a gray colour on one ſide, but is inclining to a red on the other, having ſome broad ſpots of a dark colour all over; the fleſh is commonly hard and dry, ſo that it is not very much eſteemed. It is in ſeaſon in march.

80. Pyrus (*Union*) ſativa, fructu brumali maximo pyramidato, dilutè virente. *The Union Pear, otherwiſe called Dr. Uvedale's St. Germain.* This is a very large long Pear, of a deep green colour, but the ſide next the ſun ſometimes changes to a red as it ripens. This is not fit for eating, but bakes very well; and being a great bearer, and a very large fruit, deſerves a place in every good collection. It is in ſeaſon from Chriſtmas to april.

There are many other ſorts of Pears, which are ſtill continued in ſome old gardens; but as thoſe here mentioned are the beſt ſorts known at preſent, it would be needleſs to enumerate a great quantity of ordinary fruit; ſince every one who intends to plant fruit-trees, would rather chuſe thoſe which are the moſt valued, the expence and trouble being the ſame for a bad ſort of fruit as a good one. Indeed I have inſerted many more than are really worth planting, in order to pleaſe ſuch who are fond of great variety; but whoever has a mind to make choice of ſuch only as are good, may eaſily diſtinguiſh them, by attending to the account given of each ſort, and hereby every perſon is at liberty to pleaſe himſelf; for it is not every one who prefers a Beurré Pear, though that is generally eſteemed the very beſt in its proper ſeaſon; there are ſome who admire the Meſſire Jean, for the firmneſs of its fleſh, which to others is a great objection againſt it; and as ſome eſteem the breaking, and others the melting Pears, I have diſtinguiſhed them by their deſcriptions in ſuch a manner, that every one may make choice of the kinds of fruit which are agreeable to their palate; and the different ſeaſons in which each kind is in eating, being exhibited (allowing a little for the difference of ſeaſons, which are earlier ſome years than others) it is not very difficult for a perſon to make a collection of good Pears to ſucceed each other throughout the ſeaſon of theſe fruits, both for eating and baking.

The time of each fruit ripening, as here ſet down, is taken at a mediüm for ſeven years, and in the neighbourhood of London, where all ſorts of fruit generally ripen a fortnight or three weeks earlier than in almoſt any part of England; and it is very obvious to every perſon who will attend to the culture of fruit-trees, that their time of ripening is accelerated by long cultivation; for many of the ſorts of Pears, which ſome years paſt rarely became ripe in England, unleſs they grew againſt the beſt aſpected walls, are now found to ripen extremely well on eſpaliers and dwarfs; and thoſe Pears which ſeldom were in eating till january, are ripe two months earlier.* There is alſo a very great difference in their time of ripening in different ſeaſons, for I have known the fruit of a Pear-tree in one year all ripe and gone by the middle of october, and the very next year the fruit of the ſame tree has not been fit to eat till the end of december, ſo that allowance ſhould be made for theſe accidents. The Beſi de Chaumontelle Pear, about forty years paſt, was ſeldom fit to eat before february, and has continued good till the middle of april, but now this Pear is commonly ripe in november; and when it is planted on a warm ſoil, and againſt a good aſpected wall, it is in eating the middle or end of october. This forwarding of the ſeveral kinds of Pears, may be in ſome meaſure owing to the ſtocks upon which they are graſted; for if they are graſted upon early ſummer Pear ſtocks, they will ripen much earlier than when they are upon hard winter Pear ſtocks; and if ſome of the very ſoft melting Pears were graſted upon ſuch ſtocks as are raiſed from the moſt auſtere fruit, ſuch as are never fit to eat, and of which the beſt Perry is made, it would improve thoſe fruits, and continue them much longer good; or if the common free ſtocks were firſt graſted with any of theſe hard winter Pears, and when they have grown a year, then to graft or bud theſe ſoft melting Pears upon them, it would have the ſame effect; but the Pears ſo raiſed will require a year's more growth in the nurſery, and conſequently cannot be ſold at the ſame price as thoſe which are raiſed in the common method, theſe requiring to be twice budded or graſted, ſo that there is double labour, beſide ſtanding a full year longer; but this difference in the firſt expence of the trees, is not worth regarding by any perſon who is deſirous to have good fruit; for the ſetting out in a right way is that which every one ſhould be the moſt careful of, ſince by miſtaking at firſt, much time is loſt, and an after expence of new trees often attends it.

Another cauſe of fruits ripening earlier now than they formerly did, may be from the length of time they have been cultivated; for it is very certain, that moſt ſorts of plants have been greatly forwarded and improved by culture, within the ſpace of thirty or forty years, as may be known from the ſeveral ſorts of eſculent plants, which are cultivated in the kitchen-gardens, and of which ſorts there are many which are annually improving: and if we look back to the beſt French authors who have written on the ſubject of fruit-trees, we ſhall find, that the times of ripening of many ſorts of Pears are put down a month or ſix weeks later about fifty or ſixty years ago, than they are now found to ripen about Paris; and here about London it is much the ſame, for I cannot find they are the leaſt forwarder in the times of their ripening at Paris than at London.

[2. Leaves ovate, pubeſcent even on the upper ſurface, eſpecially along the midrib. Peduncles tomentoſe. Corymb elongated, tomentoſe. Flowers very numerous, much ſmaller than in the common Pear*.

Native of Germany. Introduced in 1786, by Mr. John Græfer[b].

3. Branchlets or twigs thickiſh. Leaves elliptic or oval, petioled, ſilky and whitiſh underneath. Flowers in terminating corymbs. Fruit globular, extremely acerb, but when ripe melting and very ſweet.—Native of the mountains of Auſtria[c].

4. The Apple is a ſpreading tree, with the branches and twigs irregular and twiſting, more horizontal than in the Pear. Leaves ovate, ſerrate, the younger ones pubeſcent underneath. Stipules linear. Flowers in terminating, ſeſſile, villoſe umbels. Corollas white, but finely tinged with red on the outſide. Fruit roundiſh, umbilicate at the baſe, acid[d].

[a] Linn. mant. [b] Hort. kew. [c] Jacquin. [d] Smith.

The

The Apple in its wild ſtate, then called the Crab or Wilding, is armed with thorns, as well as the wild Pear. The peduncles are rarely ſubdivided, and are moſtly covered with ſoft down; as is the inſide, and ſometimes the outſide of the calyx*. According to Scopoli, the calyx is ſmooth on the outſide, but lanuginoſe within, and wrinkled at the baſe. Probably theſe circumſtances vary. Linnæus diſtinguiſhes two varieties of the wild Apple: the common one, with a very acid fruit, and another with a bitter fruit, which becomes ſweetiſh when ripe. This is more rare, and is found chiefly in Smoland. Perhaps it may be the ſame with the *nivalis* of Jacquin.]

Mr. Miller mentions two varieties in the fruit of the Crab, one white, the other purple towards the ſun: [it is commonly yelloviſh green with a tinge of red.] He alſo ſpeaks of a variety with variegated leaves; but when the trees grow vigorous, the leaves ſoon become plain.

[Haller thus diſcriminates the Apple tree. It has many things in common with the Pear tree, but the leaf is more ſhortly mucronate, leſs manifeſtly ſerrate, ſubhirſute underneath. The flowers tinged with red, and ſmelling very ſweet. The peduncle ſhorter. The ſtamens uſually from nineteen to twenty-five: (in the Pear twenty-two. Pollich aſſigns nineteen as the limit in the Apple, twenty-one in the Pear.) The fruit round, hollowed at the peduncle, depreſſed at top, leſs aſtringent but more acid than the Pear, of a ſofter texture. The Apple has woody threads paſſing through it from the peduncle, ten of which are regularly diſpoſed round the capſules, and tend to the calyx. It is ſaid that the fruit rots, when theſe are broken. The Pear alſo has them, but they are not ſo diſtinct, on account of the calculary or ſtony congeries—In the Apple they are placed very regularly, one at the point of each cell of the capſule, and one in the middle between the other five. They are very apparent on a tranſverſe ſection of the fruit. The cells are differently ſhaped in the two fruits: in the Apple they are narrow and pointed at both ends; in the Pear they are obovate, broad exteriorly, and drawing to a point at the end next the centre of the fruit. The Pear, however it may vary in ſhape, ſize, colour, taſte, &c. by cultivation, is generally convex and lengthened out at the baſe: whereas in the Apple it is always concave there. Beſides this, the leaves of the Apple are commonly wider in proportion to their length, of a yellower green above, and whitiſh underneath; whereas in the Pear, they are dark green above, and quite ſmooth on both ſides: their vaſcular ſyſtem is very different, being looſe in the Apple, and very cloſe in the Pear; hence the leaves of the latter are much ſtouter, and more permanent. Laſtly the growth of theſe trees is quite different; the Pear being lofty and upright, the Apple low and ſpreading.

The wood of the wild Apple is tolerably hard: it turns very clean; and when made into cogs for wheels, acquires a poliſh, and laſts a long time. The bark affords a yellow dye. The acid juice of the fruit is called Verjuice, and is much uſed in recent ſprains, and in other caſes, as an aſtringent or repellent. With a proper addition of ſugar, it is probable that a very grateful liquor might be made with the juice, little inferior to Rheniſh wine†. Lightfoot affirms, that the Crab mixed with cultivated Apples, or even alone, if thoroughly ripe, will make a ſound maſculine Syder. Every body knows that Syder is made from the juice of a variety of cultivated Apples preſſed, and fermented. Pomatum is ſo called becauſe the lard is or ought to be beat up with the pulp of Apples. This fruit, when ripe is laxative; the juice is excellent in the dyſentery; boiled or roaſted Apples fortify a weak ſtomach; Scopoli recovered from a weakneſs of the ſtomach and indigeſtion by uſing them; and they are equally efficacious in putrid and malignant fevers with juice of Lemons or Currants.

The Apple is a native of Europe; but whence and how we acquired the numerous cultivated varieties of this fruit is not known.

* Engl. bot. † Withering.

Parkinſon has fifty-ſeven varieties, beſides Sweetings and Crabs. Ray has ſeventy-eight: he has ſelected the beſt of his time, (1688) and has diſtributed them into four ſections.

First. *Early or Summer Apples.*

1. The Ginetting or Juneting.
2. The Margaret or Magdalene.
3. The King Apple.
4. The Aromatick or Golden Ruſſetting.
5. The Flax Apple.
6. The Spire Apple.
7. The Summer Queening.
8. The Go-no-further, or Cat's-head.
9. The Golden Pippin.
10. The good Houſewife or Bontradue.
11. The Giant Apple.
12. The Pomewater.
13. The Summer Pearmain.
14. The Kirton or Holland Pippin. In Suſſex, Broad-eye.
15. The Orange Apple.
16. Summer Belleboon (Belle & Bonne.)
17. The Paradiſe Apple.
18. The Famagusta.
19. The Codling.
20. The Coſtard Apple. So much eſteemed formerly that dealers in Apples were called Coſtar-mongers.
21. The Sops in Wine.

Secondly. *Provincial Apples.*

1. The Stokin or Stoken Apple. Probably from Stoke in Hereſordſhire.
2. The Golden Renet. Peculiar to Hertford.
3. The Darling. A nice fruit of Cheſhire.
4. The Angel's-bit. Famous chiefly in Worceſterſhire.
5. The Harvey Apple. From the famous Dr. Gabriel Harvey. Eſteemed at Cambridge. Large, of a whitiſh green colour, for the moſt part with black ſpots, ſcarcely laſting beyond Chriſtmas.
6. The Quarrington of Devonſhire.

Thirdly. *Winter or keeping Apples.*

1. The winter Queening.
2. The Quince Apple.
3. The winter Pearmain.
4. The Nonefuch.
5. The Pealing.
6. The Leather-coat, or winter John.
7. The Pome-roy, i. e. King of Apples.
8. The Lording.
9. The July-flower (Gilliflower) Apple.
10. The Pear Apple.
11. The Greening.
12. Lone's Pearmain.
13. The green Ruſſetting.
14. The red Ruſſetting.
15. The winter Fillet or Violet.
16. The winter Belle and Bonne.
17. The Oaken Pin.
18. The John Apple, or Deux Ans.
19. The Weſtbury.
20. The winter Reed.
21. The Flower of Kent.
22. The winter Cheſtnut.
23. The Maligar Apple.
24. The ſhort Tart.
25. The Pelmell.
26. Thrift.
27. Winter Clary.
28. Fig Apple.
29. White Pippin; in Eſſex the Renet.
30. Kentiſh Pippin.
31. French Pippin.

Fourthly, *Syder Apples.*

1. The Red-ſtreak.
2. The Bromſberry Crab.
3. The Golden Pippin.
4. The Gennet-moil.
5. The Weſtbury Apple.
6. The white and red Maſt Apples.
7. The John Apple.
8. The Underleaf.
9. The winter Fillet.
10. Elliott's.

11. Stocken Apple.
12. Bitter Scale.
13. Claret-wine Apple.
14. Arrier Apple.
15. Richard's or Orange Apple.
16. Coling Apple.
17. Olive Apple.
18. Fox-whelp.
19. Pippins and Pearmains mixt.
20. The Gilliflower Apple.

The above liſt of Mr. Ray's, was furniſhed by his friend Tancred Robinſon, from the information of the moſt ſkilful gardeners then about London. We cannot avoid obſerving how many of them have fallen into utter diſuſe within a century.

Rea enumerates only twenty choice fruits, grafted on the Paradiſe Apple, for walls, or dwarf hedge-trees in large gardens.

1. Juniting.
2. King Apple.
3. Margaret or Magdalen.
4. Famagusta.
5. Grar.
6. Good Houſwife.
7. Rome de Rambures.
8. Winter Queening.
9. Quince Apple.
10. Red Ruſſet.
11. Round Ruſſet Harvy.
12. Carliſle Pippin.
13. Bridgewater Pippin.
14. Lincoln Rennet.
15. Nonſuch.
16. Royal Pearmain.
17. Kirton Pippin.
18. Go-no-further.
19. Darling.
20. Angel's Bit.

He gives a liſt of ſixty-two ſorts proper for Orchards: and for Syder Apples refers to Mr. Evelyn's Pomona. This treatiſe gives no particular liſt, but they may be found among Mr. Ray's.

Mr. Hartlib ſpeaks of one who had 200 ſorts, and verily believes there are near 500 in this iſland.

Phillips, in his poem entitled Cyder, thus enumerates the moſt eſteemed Apples—

" The *Pippin* burniſht o'er with gold, the *Moile*
" Of ſweeteſt hony'd taſte, the fair *Permain*,
" Temper'd, like comlieſt nymph, with red and white,
" Salopian acres flouriſh with a growth
" Peculiar, ſtyl'd the *Ottley*: be thou firſt
" This Apple to tranſplant; if to the name
" Its merit anſwers, no where ſhalt thou find
" A wine more priz'd, or laudable of taſte.
" Nor does the *Eliot* leaſt deſerve thy care,
" Nor *John-Apple*, whoſe wither'd rind, entrench
" With many a furrow, aptly repreſents
" Decrepid age; nor that from *Harvey* nam'd,
" Quick-reliſhing: Why ſhould we ſing the *Thrift*,
" *Codling*, or *Pomroy*, or of pimpled coat
" The *Ruſſet*, or the *Cat's-head*'s weighty orb,
" Enormous in its growth———
" But how with equal numbers ſhall we match
" The *Muſk*'s ſurpaſſing worth! that earlieſt gives
" Sure hopes of racy wine, and in its youth,
" Its tender nonage, loads the ſpreading boughs
" With large and juicy offspring, that defies
" The vernal nippings, and cold ſyderal blaſts!
" Yet let her to the *Red-ſtreak* yield, that once
" Was of the ſylvan kind, unciviliz'd,
" Of no regard, till Scudamore's ſkilful hand
" Improv'd her, and by courtly diſcipline
" Taught her the ſavage nature to forget:
" Hence ſtyl'd the *Scudamorean* plant; whoſe wine
" Whoever taſtes, let him with grateful heart
" Reſpect that ancient loyal houſe———"

Mr. Knight affirms of theſe famous fruits, that the Moil and Redſtreak, with the Muſts and Golden Pippin, are in the laſt ſtage of decay; and the Stire and Fox-whelp are haſtening rapidly after them. The Red-ſtreak, ſo much celebrated by the writers of the laſt century, appears almoſt to have ſurvived its fame as a Cider-fruit; and indeed if it never poſſeſſed greater excellence than it does at preſent, it has certainly been much over-rated. But Mr. Knight ſuſpects that each kind of Apple is beſt calculated for Cider, when the tree has attained its maturity, and before it decays. Not that he thinks the flavour of the fruit is neceſſarily debaſed by the age of the variety; but merely that the crop in the aggregate ripens leſs perfectly, owing to the weak ſtate of ſome of the diſeaſed branches[a].]

Mr. Miller gives the following account of the varieties of Apples.

I ſhall firſt mention a few of thoſe ſorts of Apples which have been introduced from France, (Duham. 1. 322. t. 1—14.) which were moſt of them grafted on Paradiſe ſtocks, and were for ſome time much eſteemed, and ſhall mention thoſe of our own growth afterwards.

Pomme de Rambour, Duham. t. 10. The Rambour is a very large fruit, of a fine red next the ſun, and ſtriped with a paſe or yelloviſh green. This ripens very early, commonly about the end of auguſt, and ſoon grows mealy, therefore is not eſteemed in England.

Pomme de Courpendu, Duham. t. 6. the hanging body. This is a very large Apple, of an oblong figure, having ſome irregular riſings or angles, which run from the baſe to the crown; it is of a red caſt on the ſide towards the ſun, but pale on the other ſide; the foot-ſtalk is long and ſlender, ſo that the fruit is always hanging downward, which occaſioned the French gardeners to give it this name.

The Rennette-blanche, or White Renette, or French Rennette, Duham. n. 17. This is a large fine fruit, of a roundiſh figure, and of a pale green, changing a little yelloviſh when ripe, having ſome ſmall gray ſpots; the juice is ſugary, and it is good for eating or baking; it will keep till after Chriſtmas ſound.

The Rennette-griſe, Duham. t. 9. This is a middle-ſized fruit, ſhaped like the Golden Rennette, but is of a deep gray colour on the ſide next the ſun, but on the other ſide intermixed with yellow; it is a very juicy good Apple, of a quick flavour. It ripens in october, and will not keep long.

Pomme d'Api, Duham. t. 11. This is a ſmall hard fruit, of a bright purple colour on the ſide next the ſun, and of a yelloviſh green on the other ſide; it is a very firm fruit, but has not much flavour, ſo it is only preſerved by ſome perſons by way of curioſity. It keeps a long time ſound, and makes a variety in a diſh of fruit.

Le Calville d'Automne, the Autumn Calville. This is a large fruit of an oblong figure, of a fine red colour towards the ſun. The juice is vinous, and much eſteemed by the French.

Fenouillat ou Pomme d'Anis, Duham. t. 5. the Fennel, or Aniſe Apple. This is a middle-ſized fruit, a little longer than a Golden Pippin, of a grayiſh colour. The pulp is tender, and has a ſpicy taſte like Aniſe-ſeed; the wood and the leaves are whitiſh.

Pomme Violette, Duham. n. 7. the Violet Apple. This is a pretty large fruit, of a pale green, ſtriped with deep red to the ſun. The juice is ſugary, and has a flavour of Violets, which occaſioned the name.

There are not above two or three of theſe which are much eſteemed in England, viz. the French Rennette, the Rennette-griſe, and the Violet Apple; the others being early fruit, which do not keep long, and their fleſh generally mealy, do not deſerve to be propagated, as we have many better fruits in England.

I ſhall next put down thoſe ſorts of Apples which are beſt eſteemed in England, placing them in the order according to their time of ripening.

The firſt Apple which is brought to the markets, is the Codlin. This fruit is ſo well known in England, that it is needleſs to deſcribe it.

The next is the Margaret Apple: this fruit is not ſo long as the Codlin, of a middling ſize; the ſize next the ſun changes to a faint red, when ripe; the other ſide is of a pale green; the fruit is firm, of a quick pleaſant taſte, but does not keep long.

The Summer Pearmain is an oblong fruit, ſtriped

[a] Treatiſe on the Culture of the Apple and Pear, 1797.

with

with red next the ſun; the fleſh is ſoft, and in a ſhort time is meally, ſo that it is not greatly eſteemed.

The Kentiſh Fill-Baſket is a ſpecies of Codlin, of a large ſize, and ſomewhat longer ſhaped than the Codlin; this ripens a little later in the ſeaſon, and is generally uſed for baking, &c.

The Tranſparent Apple: this was brought to England a few years ſince, and was eſteemed a curioſity; it came from Peterſburgh, where it is affirmed to be ſo tranſparent, as that the kernels may be perfectly ſeen, when the Apple is held to the light; but, in this country, it is a meally inſipid fruit, not worth propagating.

Loan's Pearmain: this is a beautiful fruit, being of a middling ſize; the ſide next the ſun is of a beautiful red, and ſtriped with the ſame colour on the other; the fleſh is vinous, but as it ſoon grows meally, it is not greatly eſteemed.

The Quince Apple: this is a ſmall fruit, ſeldom larger than the Golden Pippin, but is in ſhape like the Quince, eſpecially towards the ſtalk; the ſide next the ſun is of a ruſſet colour, on the other ſide inclining to yellow: this is an excellent Apple for about three weeks in ſeptember, but will not keep much longer.

The Golden Renette is a fruit ſo well known in England, as to need no deſcription; this ripens about michaelmas, and for about a month is a very good fruit, either for eating raw or baking.

The Aromatic Pippin is alſo a very good Apple: it is about the ſize of a Nonpareil, but not ſo flat, it is a little longer; the ſide next the ſun is of a bright ruſſet colour; the fleſh is breaking, and has an aromatic flavour. It ripens in october.

The Hertfordſhire Pearmain, by ſome called the Winter Pearmain: this is a good ſized fruit, rather long than round, of a fine red next the ſun, and ſtriped with the ſame colour on the other ſide; the fleſh is juicy, and ſtews well, but is not eſteemed for eating by any nice palates. This is fit for uſe in november and december.

The Kentiſh Pippin is a large handſome fruit, of an oblong figure; the ſkin is of a pale green colour; the fleſh is breaking, and full of juice, which is of a quick acid flavour. This is a very good kitchen fruit, and will keep till february.

The Holland Pippin is larger than the former; the fruit is ſomewhat longer, the ſkin of a darker green, and the fleſh firm and juicy. This is a very good kitchen fruit, and will keep late in the ſeaſon.

The Monſtrous Renette is a very large Apple, of an oblong ſhape, turning red toward the ſun, but of a dark green on the other ſide; the fleſh is apt to be meally, ſo it is not much valued by thoſe who are curious, and only preſerved for the magnitude of the fruit.

The Embroidered Apple is a pretty large fruit, ſomewhat ſhaped like the Pearmain, but the ſtripes of red are very broad, from whence the gardeners have given it this title: it is a middling fruit, and is commonly uſed as a kitchen Apple, though there are many better.

The Royal Ruſſet, by ſome called the Leather Coat Ruſſet, on account of the deep ruſſet colour of the ſkin; this is a large fair fruit, of an oblong figure, broad towards the baſe; the fleſh is inclinable to yellow. This is one of the beſt kitchen Apples we have, and is a very great bearer: the trees grow large and handſome, and the fruit is in uſe from october till april, and is alſo a pleaſant fruit to eat.

Wheeler's Ruſſet is an Apple of a middling ſize, flat, and round; the ſtalk is ſlender, the ſide next the ſun of a light ruſſet colour, and the other ſide inclining to a pale yellow, when ripe; the fleſh is firm, and the juice has a very quick acid flavour, but is an excellent kitchen fruit, and will keep a long time.

Pile's Ruſſet is not quite ſo large as the former, but is of an oval figure, of a ruſſet colour to the ſun, and of a dark green on the other ſide; it is a very firm fruit, of a ſharp acid flavour, but is much eſteemed for baking, and will keep ſound till april, or later, if they are well preſerved.

The Nonpareil is a fruit pretty generally known in England, though there is another Apple which is frequently ſold in the markets for it, which is what the French call Haute-bonne; this is a larger fairer fruit than the Nonpareil, more inclining to yellow; the ruſſet colour brighter, and it is earlier ripe, and ſooner gone; this is not ſo flat as the true Nonpareil, nor is the juice ſo ſharp, though it is a good Apple in its ſeaſon; but the Nonpareil is ſeldom ripe before Chriſtmas; and where they are well preſerved they will keep till may perfectly ſound; this is juſtly eſteemed one of the beſt Apples that have been yet known.

The Golden Pippin is a fruit almoſt peculiar to England; there are few countries abroad where this ſucceeds well, nor do they produce ſo good fruit in many parts of England as in ſome meaſure, were to be wiſhed; which, in free ſtocks, which enlarges their being grafted on valuable, becauſe the fleſh is fruit, but renders it leſs your ſo quick, ſo is apt to be dry ſo firm, nor the flafore this ſhould always be grafted meally; thereſtock, which will not canker like the on the Crab the fruit will not be ſo fair to the ſight, and though better flavoured and keep longer. it will be

There are yet a great variety of Apples, wing inferior to thoſe here mentioned, I have on- as thoſe which are here enumerated will be ſufficient furniſh the table and the kitchen, during the whole ſeaſon of theſe fruits; ſo that where theſe ſorts can be had, no perſon of taſte will eat the other.

I ſhall here mention ſome of the Apples which are chiefly preferred for the making of Cyder, though there are in every Cyder country, new ſorts frequently obtained from the kernels; but theſe have, for ſome years, been in the greateſt eſteem.

The Red-ſtreak.
Devonſhire Royal Wilding.
The Whitſour.
Herefordſhire Under Leaf.
John Apple, or Deux-annes.
Everlaſting Hanger.
Gennet Moyle.

[In Herefordſhire, according to Mr. Marſhall[b], the *Stire* ſtands firſt in eſtimation as a Cider fruit. It is ſomewhat below the middle ſize; the form rather flat; the colour pale yellowiſh white, with ſometimes a faint bluſh on one ſide; the fleſh tolerably firm; the flavour, when fully ripe, fine. This celebrated fruit is going off.

The *Hagloe Crab* is at preſent next in eſteem. It was produced about ſeventy years ago, (1719) in a nurſery, among other ſtocks raiſed from the ſeed, by Mr. Bellamy, of Hagloe, in Glocesterſhire, grandfather of the preſent Mr. Bellamy, near Roſs in Herefordſhire, who draws from trees grafted with ſcions from this ſtock a liquor, which for richneſs, flavour, and price on the ſpot, exceeds every other. The fruit is nearly white, with a yellowiſh caſt when fully ripe, ſometimes freckled with red on one ſide: more oblong than the Stire Apple; ſoft and woolly, but not dry; with a ſheer, but when fully ripe, ſweet juice; flavour like that of the Caſhew Apple.

The *Golden Pippin* is in high eſtimation.

The old *Redſtreak* is yet in being. Fruit ſmall, roundiſh, pale-yellow with numerous faint-red ſtreaks; fleſh firm, full of juice, and when ripe finely flavoured. Little, if any genuine Red-ſtreak Cider is now made; and it probably never was equal to that from either of the preceding. The tree is of a ſingularly aukward growth; crooked, reclining, ragged and unſightly.

The *Woodcock*, another old favourite, is now going off. Fruit above the middle ſize: form ſomewhat oblong, ſet on a long footſtalk: colour of the Redſtreak, with ſome dark blood-red ſtreaks on one ſide: fleſh remarkably fine. Tree large and ſtrongly featured, forming large boughs in the Pear-tree manner.

Other favourite Cider Apples are—the *Muſt*, of which there are three varieties.

The *Pauſon*: middle-ſized and green.
The *Royal Wilding*: large and white.

[b] Gloeſterſh. 2. 251.

The

The *Dymmock Red*: middle-ſized and red.

The *Cocagee*: above the middle ſize; greeniſh white with an orange bluſh; well fleſhed and highly flavoured.

Ruſſets of various kinds, particularly the *Longney*.

Bromley, *Foxwhelp*, *Red Crab*, *Queening*, all large red fruit.

Theſe will yield in their turn to other varieties, and it is now a general opinion, that Apples whilſt are the creatures of art and cultivation, cannot be preſerved beyond a certain period.

Mr. Grimwood, a nurſeryman of eminence at Kenſington, is of opinion that it is not a decline in the quality of the fruit, but in the tree, owing either to want of health, the ſeaſon, the ſoil, the mode of planting, or to the ſtock which they are grafted on, being too often raiſed from the ſeed of Apples in the ſame place or county. It appears, he ſays, from the ableſt men in his profeſſion, that they never found a real decline in any one kind of fruit, but from the above cauſes[t].

The law of nature, Mr. Marſhall obſerves, though it ſuffer man to improve the fruits which are given us, appears to have ſet bounds to his art, and to have numbered the years of his creations. Artificial propagation cannot preſerve the varieties in perpetuity. A time arrives, when they can be no longer propagated with ſucceſs. All the old Cider-fruits are now loſt, or elſe ſo far on the decline, as to be deemed irrecoverable.

The popular idea among orchard-men (in Herefordſhire) is, that the decline of the old fruits is owing to a want of freſh grafts from abroad; under a notion that the higheſt-flavoured Apples grow there, in a ſtate of nature, as the Crab does in this iſland. It ſcarcely needs to be obſerved that this is a groſs error.

That the firſt improved fruits of our anceſtors were fetched from the continent is highly probable[u]. Mr. Lightfoot informs us that the Apple is remarkable for its longevity; and that it is ſaid ſome trees in Herefordſhire have lived a thouſand years. This report is tranſcribed from Haller, without acknowledgment, as is uſual with Mr. Lightfoot. Haller quotes *Hereford orchards*, a book or pamphlet, which I do not recollect having ſeen. But no one, I preſume, will be diſpoſed to admit ſuch a report, unleſs we could have better evidence than mere tradition.

According to Stow, Carps and Pippins were brought into England by Mafcall. It was the plain induſtry, ſays Mr. Evelyn[x], of one (Richard) Harris, a fruiterer to King Henry the Eighth, that the fields and environs of about thirty towns in Kent only, were planted with fruit, (from Flanders) to the univerſal benefit, and general improvement of that county to this day; as by the noble example of my Lord Scudamor, and of ſome other publick-ſpirited gentlemen in thoſe parts, all Herefordſhire is become, in a manner, but one intire orchard.

Lord Scudamor was ambaſſador to the court of France in the time of King Charles the Firſt; and having collected in Normandy ſcions of Cyder-Apple trees, when he returned to England, encouraged the grafting them throughout the county of Hereford[y].

But theſe and others were partial introductions. There can be no doubt but that the Apple has been cultivated in England time immemorial, for deſerts, for the kitchen, and for cyder.

It is probable that the ſorts originally imported have long ago been loſt, and though we have ſtill ſome Apples by the ſame name with thoſe in Parkinſon, (1629) yet it is by no means certain that they are the ſame fruit; and many of the numerous varieties we are at preſent poſſeſſed of, were raiſed from ſeed in this country[z].

Mr. Knight obſerves[a], that the exiſtence of every variety of Apple appears to be confined to a certain period, that no one of them now cultivated ſeems to be more than two hundred years old; and that all efforts which have been hitherto made to propagate ſcalthy trees of thoſe varieties which have been long in cultivation, have been entirely unſucceſsful: but of this more under the head of Propagation and Culture.

5. It is ſuppoſed that this may have ſprung from the common Apple. The leaves are pubeſcent underneath. Peduncles one-flowered at the axils of the leaves towards the end of the branches, forming a ſort of umbel. Petals yelloviſh green. Styles five, filiform, ſmooth; with club-ſhaped ſtigmas[b]. Willdenow did not obſerve any ſtamens.

6. The Chineſe Apple tree, when it bloſſoms in perfection, anſwers truly to the name of *ſpectabilis*; a more ſhowy tree can ſcarcely be introduced to decorate the ornamental plantation. It bloſſoms about the end of april or beginning of may. The flowers are large, of a pale red when open, and ſemi-double; the buds are of a much deeper hue. The fruit is of little account, and but ſparingly produced. Trees of this ſpecies are to be met with in ſome gardens twenty or thirty feet high[c]. Cultivated in 1780, by John Fothergill, M.D.[d]

7. This has a ſtrong woody ſtem, ſending out many ſide branches, and covered with a ſmooth brown bark. The leaves are ſhaped like thoſe of the Cherry-tree: they are of a deep green on their upper ſide, but paler on their under, ſlightly ſerrate, and on long footſtalks. The flowers come out in bunches from the ſide of the branches on long ſlender peduncles; the petals are white, and ſhaped like thoſe of the Pear-tree: they appear in april, and are ſucceeded by roundiſh fruit, about the ſize of large Duke Cherries, changing to a yelloviſh colour variegated with red, of a very auſtere taſte, decaying like the fruit of the Medlar, and then more palatable.

It is ſuppoſed to be a native of Siberia; and bore fruit in the botanic garden at Chelſea before the year 1760[e].

[8. This is a tree with even branches. Leaves like thoſe of Cornus, ovate, finely ſerrate, even on both ſides. Petioles the length of the leaf, at the baſe connecting two linear-lanceolate ſtipules. Peduncles four, filiform, even, axillary, cluſtered, quite ſimple, one-flowered, the length of the petioles. Germ inferior, globular, ſmooth, ſmall. Petals ſeſſile, oval, concave, white, biggith. Stamens twenty, ſhorter than the piſtils; which are ſhorter than the corolla. Fruit roundiſh, five-celled, red. Seeds in each cell two, callous. Calyx minute, deciduous[f].

Pallas deſcribes the roots as ſtriking deep, and throwing up abundance of ſuckers, the trunk ſcarcely three or four feet high, ſeldom thicker than the human arm, commonly twiſted, covered with a rugged, aſh-coloured bark, full of chinks; the wood whitiſh with gray ſtripes; the whole forming a ſpheroidal head, a fathom or a little more in height: the leaves ovate-acuminate, ſerrate, ſmooth, on long petioles, and ſomewhat pendulous; petioles ſubpubeſcent; ſtipules briſtle-ſhaped, ſlender. Umbels from four to eight-flowered, accompanied with leaves, on very long ſlender even peduncles. Fruit a pome, the ſize of a ſmall Cherry, on a long peduncle, globular, green but turning yellow and more or leſs tinged with red; five-celled, with two oblong ſharp ſeeds in each cell: the pulp is reddiſh with an acid juice, which is uſed for making Quas and Punch in Siberia, where it grows naturally, and is common about the lake Baikal and in the country beyond it, in Dauria, and as far as Ircut; but not in other parts of that extenſive country: it affects the banks of rivers, and low ſpots near them; flowering in may, and ripening its fruit in auguſt and ſeptember[g]. With us it flowers in april; and was introduced in 1784, by Mr. John Græfer[h].

9. Umbel on ſmooth peduncles. Calyxes ſmooth on the outſide; tomentoſe within. Leaves like thoſe of the Apple, but more ſmooth, and more finely ſerrate[i].]

The leaves of this are longer and narrower, and are cut into acute angles on their ſides. The flowers have a fragrant odour, perfuming the North American woods in their ſeaſon. The inhabitants plant them for ſtocks to graft other Apples upon.

[Kalm ſays, that this tree is rather ſcarce in New Jerſey, but plentiful in Penſylvania.

Gronovius firſt remarked it in Virginia. They frequently plant it near their farms, on account of the fine ſmell which the flowers afford, ſomewhat like the Raſpberry. They expand in the beginning of may. The fruit is ſmall, ſour, and unfit for any thing but to make vinegar of. It lies under the trees all winter, acquires a yellow colour, and ſeldom begins to rot till ſpring comes on.

It flowers here in may; and appears by Furber's catalogue to have been cultivated here in 1724[a].

10. Native of North America. It flowers here in may; and was cultivated in 1750, by Mr. Chriſtopher Gray[b], nurſery-man at Fulham.

11. This is a ſhrub or ſmall tree, wholly ſmooth. Branches and branchlets alternate, flexuoſe, even, aſh-coloured, erect. Leaves many on the branchlets, from every other bud, ſubpetioled, ovate or wedge-ſhaped, blunt, ſometimes emarginate, ſerrate, above nerved, deep green; underneath netted, pale; ſpreading, ſmooth, unequal, an inch long. Flowers on the branchlets alternate, ſubpeduncled, in pairs. Perianth one-third of the length of the corolla, green below, purple above. Corolla fleſh-coloured. Stamens thirty and upwards. Styles about the length of the filaments; with trifid, reflex, yellow ſtigmas. Pome ſubglobular, ſmooth, the ſize of a Walnut, five-celled, with ſeveral ſeeds to each cell.—Native of Japan.

12. The Quince tree is a low crooked and diſtorted tree, covered with a brown bark, and much branched. Leaves roundiſh or ovate, entire, above duſky green, underneath whitiſh, on ſhort petioles. Flowers large. Corolla pale red or white. Calyx ſpreading, ſerrate, the length of the corolla. Fruit a pome, varying in ſhape in the different varieties—globular, oblong or pear-ſhaped.]

Mr. Miller has three varieties: 1. C. oblonga or Pear Quince, with oblong-ovate leaves, and an oblong fruit lengthened at the baſe. 2. C. maliformis or Apple Quince, with ovate leaves and a rounder fruit. 3. C. luſitanica or Portugal Quince, with obovate leaves; and an oblong fruit which is more juicy and leſs harſh than the others, and therefore the moſt valuable.

[This agrees with the ſpecies immediately preceding in having ſeveral ſeeds in each cell[b].

The Quince has its Latin name *Cydonia Malus* and the Greek Μηλέα Κυδωνία, from Cydon in Crete, whence it is ſaid to have been originally brought. It is now reputed to be a native of Auſtria, Germany, and ſome other parts of Europe. It flowers in may and june; and was cultivated here in the time of Gerarde; (1597) probably much earlier.

The Quince has a peculiar ſmell, and an auſtere taſte when raw, but prepared is much eſteemed. The expreſſed juice, repeatedly taken in ſmall quantities, is ſaid to be cooling, reſtringent and ſtomachic; uſeful in nauſea, vomitings, nidorous eructations, and ſome alvine fluxes. Formerly this juice was ordered to be made into a ſyrup; but the only preparation of the Quince now directed is a mucilage of the ſeeds, made by boiling a dram of them in eight ounces of water, till it acquires a proper conſiſtence. This has been recommended in apthous affections, and excoriations of the mouth and fauces. It may be a more pleaſant mucilage, but it is certainly a leſs efficacious one, than that of the ſimple gums[c].

13. This is a low buſhy tree, a fathom or a fathom and half in height, branched very much, and ſhooting up from the root. Trunk ſeldom more than an inch and half in diameter; with a thin browniſh aſh-coloured bark, and a white, uniform and very hard wood, poliſhing like bone. Leaves in bundles as it were on the ſhoots, but ſcattered alternately on the thorny branches, attenuated into the petiole, lanceolate, ſtiffiſh, for the moſt part quite entire, ſubſerrate towards the tip, covered with a ſmooth nap, duſky green above, glaucous-hoary underneath. Stipules none. Stamens about ſeventeen. Fruit ſolitary or two together, turbinate, ſubvilloſe, attenuated into a cylinder at the baſe, rounded above. Seeds in each of the five cells two, ovate-acute, flat on one ſide, of a yellow-teſtaceous colour. It flowers at the end of april, and perfects its fruit in june; but the fruit is ſmall and of no value.

Native of Siberia, in the ſandy deſert between the rivers Teree and Cuma, &c. on Caucaſus, and in Perſia[d]. Introduced in 1780, by Peter Simon Pallas, M. D.[e]

Some modern authors have united to this genus ſeveral ſpecies of *Meſpilus* and *Cratægus*; but I have followed Linneus, fully aware that there is no end to theſe changes in natural orders.]

PROPAGATION AND CULTURE.

The ripening of Pears may be accelerated by the method of pruning and managing theſe trees, which is greatly improved within the ſpace of a few years paſt; for if we look into the directions which are given by the beſt writers on this ſubject, we ſhall ſoon diſcover how little they knew fifty years ago, of the true method of pruning and managing moſt ſorts of fruit-trees, ſcarce one of them making any difference in the management of the different kinds of fruit.

Pears are propagated by budding or grafting them upon ſtocks of their own kind, which are commonly called free ſtocks, or upon Quince ſtocks, or White-thorn, upon all which theſe fruits will take; but the latter ſort of ſtock is now ſeldom uſed, becauſe they never keep pace in their growth with the fruit budded or grafted upon them; as alſo becauſe the fruit upon ſuch ſtocks are commonly drier, and more apt to be ſtony, than when they are upon Pear ſtocks. Quince ſtocks are greatly uſed in the nurſeries for all ſorts of Pears which are deſigned for dwarfs or walls, in order to check the luxuriancy of their growth, ſo that they may be kept within compaſs better than upon free ſtocks. But againſt the general uſe of theſe ſtocks, for all ſorts of Pears indifferently, there are very great objections: 1ſt, Becauſe ſome ſorts of Pears will not thrive upon theſe ſtocks, but in two or three years decay, or at moſt will but juſt keep alive. 2dly, Moſt of the ſorts of hard breaking Pears are rendered ſtony, and good for little; ſo that whenever any of theſe ſorts are thus injudiciouſly raiſed, the fruit, although the kind be ever ſo good, is condemned as good for nothing by ſuch as are not well acquainted with it, when the fault is entirely owing to the ſtock on which it was grafted. On the contrary, moſt melting buttery Pears are greatly improved by being upon Quince ſtocks, provided they are planted on a ſtrong ſoil; but, if the ground be very dry and gravelly, no ſort of Pear will do well upon Quince ſtocks.

Theſe general directions being given, there is no occaſion to repeat any part of the method in which theſe ſtocks are raiſed, and the fruits budded or grafted thereon, which has been already mentioned under the article of NURSERY.

The diſtance which theſe trees ſhould be planted either againſt walls or eſpaliers, muſt not be leſs than forty feet; for if they have not room to ſpread on each ſide, it will be impoſſible to preſerve them in good order, eſpecially thoſe on free ſtocks, for the more theſe trees are pruned, the more they will ſhoot; and, as I ſaid before, many ſorts of Pears produce their bloſſom-buds firſt at the extremity of the former year's ſhoots, ſo that when they are ſhortened, the fruit will be cut away, and this cannot be avoided, where the trees have not room allowed in their firſt planting.

This diſtance, I doubt not, will be objected to by many who have not fully attended to the growth of theſe trees, eſpecially as it hath been the general

[a] Hort. kew. [b] Idem. [b] Willdenow. [c] Woodville. [d] Pallas. [e] Hort. kew.

practice of moſt gardeners to plant theſe trees at leſs than half the diſtance which is here mentioned; but, whoever will be at the trouble to view any of theſe trees which have been ſome years ſtanding, they will always find, if by accident, one of theſe trees has been planted againſt a building, where the branches have had room to ſpread, that this tree has produced more fruit than twelve trees which have been crouded cloſe, and have not room for their branches to extend. There are ſome Pear-trees now growing, which ſpread more than fifty feet in length, and are upwards of twenty feet high, which produce a much greater quantity of fruit than if there had been three trees in the ſame room they would have done, as there are examples enough to prove, where trees are planted againſt houſes and the ends of buildings at about twelve feet, or much leſs diſtance, becauſe there is height of walling for them to grow, which is the reaſon commonly given by thoſe who plant theſe trees ſo cloſe together. But one tree will bear more fruit, when the branches are trained horizontally, than three or four trees, whoſe branches are led upright, and there never can be any danger of the upper part of the wall being left naked or unfurniſhed; for I have ſeen a Pear-tree which has ſpread more than fifty feet in width, and covered the wall upwards of thirty-ſix feet in height; this was a ſummer Boncrêtien Pear, and was extremely fruitful, which rarely happens to this ſort when they are not allowed a large ſhare of room. The fineſt tree of this ſort of Pear, which I have ever ſeen, was a large ſtandard-tree in my own poſſeſſion, whoſe ſtem was not more than ten feet high, where the branches came out regularly on every ſide, and extended near thirty feet from the trunk, many of which were by the weight of the fruit in ſummer brought down to the ground, ſo they were obliged to be ſupported with poles all around the tree towards the extremity of the branches, to prevent their lying upon the ground; and this tree had its branches ſo diſpoſed as to form a natural parabola of forty feet in height, bearing from the loweſt to the higheſt branches; ſo that in a kindly ſeaſon, when the bloſſoms eſcaped the froſt, it has produced upwards of two thouſand Pears, which were much better flavoured than any of the ſame ſort which I have yet taſted. This inſtance I mention, only to ſhew how much one of theſe trees will ſpread, if proper room be allowed it; and alſo to obſerve, that as the branches of this tree had never been ſhortened, they were fruitful to their extremities. This ſhews the abſurdity of the French gardeners, who do not allow more than ten or twelve feet diſtance to theſe trees; and ſome of their moſt improved writers on this ſubject have adviſed the planting an Apple-tree between the Pear-trees, where they are allowed twelve feet; and yet theſe authors afterwards ſay, that a good Pear-tree will ſhoot three feet each way in one year; therefore, according to their own obſervation, the trees ſo planted will have their branches meet together in two or three years at moſt, and what muſt be the caſe with ſuch trees in five or ſix years is not difficult to know. But this method of planting has not been peculiar to the French, for moſt of the gardens in England have been little better planted. Indeed, thoſe perſons who were intruſted with the making and planting moſt of the Engliſh gardens, had little ſkill of their own, ſo were obliged to follow the directions of the French gardeners; of whom they had ſo great an opinion, as to get their books tranſlated, and to theſe have added ſome trifling notes, which rather betray their weakneſs; for, where they have objected to the little room which their authors had allowed to theſe trees, they have, at the moſt, allowed them but three feet more; from which it is plain, they had not conſidered the natural growth of the trees, and whoever departs from nature, may be juſtly pronounced an unſkilful gardener.

As moſt of the Engliſh gardens have been made and planted by perſons of little judgment, it is very rare to find any of them which produce much fruit; for although many of theſe gardens have been totally altered and new planted, yet they have ſeldom been much altered for the better; and the poſſeſſors have been put to the expence of removing the old trees, alſo the earth of their borders, and to purchaſe new trees, which have been planted perhaps a foot or two farther aſunder, than the old trees which were removed; ſo that when the young trees have grown a few years, they were in the ſame condition as the old, and it will be the loſs of ſo many years to the owner: but this will conſtantly be the caſe, when it is the intereſt of the perſons employed, who can ſell ſo many young trees; and the planting of three times the number of trees in a garden, more than is proper, may in ſome meaſure be aſcribed to the ſame, though in many inſtances I ſhall be inclinable to think they have proceeded from ignorance, rather than deſign.

But where fruit-trees have been thus injudiciouſly planted, if the ſtocks are healthy and good, the beſt way to recover this loſs is to dig up two or three, and leave every third or fourth tree, according to the diſtance which they were planted, and ſpread down the branches of thoſe which are left horizontally; I mean, all ſuch as are capable of being ſo brought down: but thoſe which are too ſtubborn for this, ſhould be cut off near the ſtem, where there will be new ſhoots enough produced to furniſh the wall or eſpalier; and if the ſort of fruit is not the ſame as deſired, the young branches may be budded the ſame ſummer, or grafted the following ſpring with any other ſort of Pear, and hereby many years may be ſaved; for one of theſe old trees ſo budded or grafted, will ſpread to a much greater length, and produce more fruit, when thus managed, in three years, than a new tree will in ten or twelve, eſpecially if the ground is mended. This is a method which I have practiſed with great ſucceſs, where I have been employed to mend the blunders of theſe great gardeners, as they are ſtiled, and hereby the walls and eſpaliers have been well furniſhed in a few years.

But the next thing to be done, after being furniſhed with proper trees, is preparing the ground to receive them; in doing of which, there ſhould be great regard had to the nature of the ſoil, where the trees are to grow; for, if it is a ſtrong ſtiff land, and ſubject to wet in the winter, the borders ſhould be raiſed as much above the level of the ground as you conveniently can. And if under the good ſoil there is a ſufficient quantity of lime, rubbiſh, or ſtones laid to prevent the roots of the trees from running downward, it will be of great ſervice to the trees. The borders for theſe ſhould not be leſs than eight feet broad, but, if they are twelve, it will be ſtill better. And as theſe borders may be planted with ſuch ſorts of eſculent plants as do not grow large, or whoſe roots do not grow deep, or mat together on the ſurface, theſe will do no harm to the Pear-trees; for theſe are not ſo nice in their culture as Peach and Nectarine-trees, ſo the turning the ground, and mending it for theſe crops, will rather improve than injure the trees, provided the plants do not ſhade the trees, or are not ſuffered to ſtand too long upon the borders. But all the Cabbage kind, as alſo Beans, ſhould be excluded from theſe borders, becauſe they root deep in the ground, and draw much nouriſhment from the trees.

But if the ſoil is ſhallow, and the bottom is either gravel or chalk, there muſt be a ſufficient depth of good earth laid upon the borders, ſo as to make them two feet and a half deep; for if the ground is not of this depth, the trees will not thrive well. And, in doing of this, I muſt caution every perſon not to dig out the gravel or chalk in a trench, (as is by ſome practiſed) and fill this trench with good earth; for by ſo doing, when the roots of the trees are extended to the width of the trench, they will meet with the gravel which will ſtop them, ſo that they will be confined, as if they were in tubs of earth, whereby the trees will ſoon ſhew their diſtreſs; therefore, when the gravel or chalk is removed, it ſhould be entirely taken away over the whole border, otherwiſe it will be better to raiſe the whole border above it.

If the garden is to be new-made from a field, then all the good earth on the ſurface ſhould be carefully

preſerved;

preſerved; and, if the good ground is taken out where the walks are deſigned to be made, and laid upon the borders, or in the quarters, it will add to the depth of the ſoil, and ſave expence in bringing in new earth. If the ground can be prepared one year before it is planted, the trees will thrive the better; for by laying the ground in ridges, and turning it over two or three times, it will looſen the ſoil, and render it much better for planting; but in trenching or ploughing the ground, there ſhould be great care taken not to go deeper than the ground is good, otherwiſe all the good ſoil will be buried below the roots, and the bad ground will be turned on the top, which is what I have known done at a great expence by perſons, who have been at the top of their profeſſion, and have thereby entirely ruined the gardens.

Where there is a neceſſity of bringing any freſh earth for the borders, it will be proper to do it as ſoon as poſſible, and to mix this with the ſurface of the earth of the borders, that it may be turned over two or three times, that the parts may be well mixed and incorporated before the trees are planted; and, if ſome very rotten dung is added to this, it will greatly improve it. In chuſing the earth which is to be brought into the garden, there ſhould be this care, viz. That if the natural ſoil of the garden is light and dry, then the new earth ſhould be loamy and ſtiff; but where the natural ſoil is ſtrong or loamy, then the new earth ſhould be light and ſandy, which will looſen the parts of the natural ſoil, and greatly mend it.

There are ſome perſons who recommend laying the whole depth of the borders with what they call virgin earth, that is, ſuch as is taken from a paſture where the land has not been ploughed; but if this is not brought into the garden at leaſt one year before the trees are planted, that by turning it over often it may be ſweetened, it will not be ſo good as that which is taken from a kitchen-garden, where the land is good, and has been well wrought; for by often turning and breaking the ſoil, it will be better prepared to receive the trees.

Others recommend mixing a great quantity of rotten dung with the earth of the borders, but this is not ſo proper; for, by making the ground too rich, it will only encourage the luxuriant growth of the trees; therefore it is always better to mend the borders from time to time as they may require, and not to add ſo much dung in the firſt making them.

Another care is required in making the borders on wet ground, which is to contrive ſome covered drains to convey off the water in winter, otherwiſe, by this being detained about the roots of the trees, it will greatly prejudice them; and in building the walls round a kitchen-garden, where the ground is inclinable to be wet, there ſhould be ſome arches turned in the foundations of thoſe walls which are in the loweſt part of the garden, to let off the wet.

The manner of preparing theſe trees for planting is the ſame as has been directed for other fruit-trees, viz. to cut off all the ſmall fibres from the roots, and to ſhorten ſome of the longeſt roots, and cut off all the bruiſed ones, or ſuch as ſhoot downright; this being done, you ſhould plant them in the places intended at the before-mentioned diſtance. The beſt time to plant theſe trees (if upon a middling or dry ſoil) is in october or november, leaving their heads on till ſpring, which ſhould be faſtened either to the walls or ſtakes, to prevent the wind from diſturbing their roots; and in the beginning of march their heads ſhould be cut off in the manner already directed for Peaches and other fruit-trees, obſerving alſo to lay ſome mulch upon the ſurface of the ground about their roots when they are planted, as has been ſeveral times already directed for other trees; but in wet ground the trees may be planted in february, or the beginning of march, at any time before the buds are much ſwelled, but theſe may be cut down when they are planted.

The firſt ſummer after planting, the branches ſhould be trained to a wall or eſpalier (againſt which they are planted) in a horizontal poſition, as they are produced, without ſhortening them; and the michaelmas following, ſome of theſe ſhoots ſhould be ſhortened down to five or ſix eyes, in order to obtain a ſufficient quantity of branches, to furniſh the lower part of the wall or eſpalier; but the ſhoots ought not to be ſhortened, unleſs where there is a want of branches to fill a vacancy; therefore the leſs a knife is uſed to theſe trees, the better they will ſucceed; for, whenever the ſhoots are ſtopped, it occaſions the buds immediately below the cut to ſend forth two or more ſhoots, whereby there will be a confuſion of branches, and rarely any fruit is produced with this management.

The diſtance which the branches of Pears ſhould be trained, muſt be proportioned to the ſize of their fruit; therefore ſuch ſorts, whoſe fruit are ſmall, may be allowed five or ſix inches, but the larger ſorts muſt not be leſs than ſeven or eight inches aſunder. If this be duly obſerved, and the branches carefully trained horizontally as they are produced, there will be no occaſion for ſo much cutting as is commonly practiſed on theſe trees, which, inſtead of checking their growth, does, on the contrary, cauſe them to ſhoot the ſtronger.

It is very ſurpriſing to read the tedious methods, which moſt of the writers on fruit-trees have directed for pruning theſe trees; for, by their prolix and perplexed methods, one would imagine they had endeavoured to render themſelves as unintelligible as poſſible; and this, I am ſure, may be affirmed, That it is next to impoſſible for a learner ever to arrive at any tolerable ſkill in pruning by the tedious and perplexed directions which are publiſhed by Monſieur Quintiny, and thoſe who have copied from him; for, as theſe have all ſet out wrong in the beginning, by allowing their trees leſs than half the diſtance which they ſhould be planted, they have preſcribed rules to keep them within that compaſs, which are the moſt abſurd, and contrary to all reaſon, therefore ſhould not be practiſed by thoſe perſons who are deſirous of having plenty of fruit.

I ſhall therefore only lay down a few neceſſary directions for pruning and managing theſe trees, which ſhall be done in as few words as poſſible, that a learner may the more eaſily underſtand it, and which (together with proper obſervations) will be ſufficient to inſtruct any perſon in the right management of them.

Pear-trees generally produce their bloſſom-buds firſt at the extremity of the laſt year's ſhoots, ſo that if theſe are ſhortened, the bloſſoms are cut off; but this is not all the damage, for (as I before ſaid) this occaſions the buds immediately below the cut to put forth two or more ſhoots, whereby the number of branches will be increaſed, and the tree crowded too much with wood; beſides, thoſe buds, which by this management produce ſhoots, would have only produced curſons or ſpurs, upon which the bloſſom-buds are produced, if the leading branch had not been ſhortened; therefore theſe ſhould never be ſtopped, unleſs to furniſh wood to fill a vacancy.

It is not neceſſary to provide a new ſupply of wood in Pear-trees, as muſt be done for Peaches, Nectarines, &c. which only produce their fruit upon young wood; for Pears produce their fruit upon curſons or ſpurs, which are emitted from branches which are three or four years old; which curſons continue fruitful many years, ſo that, where theſe trees have been ſkilfully managed, I have ſeen branches which have been trained horizontally upwards of twenty feet from the trunk of the tree, and have been fruitful their whole length. And if we do but carefully obſerve the branches of a healthy ſtandard-tree, which has been permitted to grow without pruning, we ſhall find many that are ten or twelve years old, or more, which are very full of theſe curſons, upon which a good number of fruit is annually produced.

During the ſummer ſeaſon theſe trees ſhould be often looked over to train in the ſhoots, as they are produced, regularly to the wall or eſpalier, and to diſplace fore-right and luxuriant branches as they ſhoot out, whereby the fruit will be equally expoſed to the air and ſun, which will render them more beautiful and better taſted than when they are ſhaded by the

branches;

branches; and by thus managing the trees in ſummer, they will always appear beautiful, and in winter they will want but little pruning.

Where Pear-trees are thus regularly trained without ſtopping their ſhoots, and have full room for their branches to extend on each ſide, there will never be any occaſion for diſbarking the branches, or cutting off the roots (as hath been directed by ſeveral writers on gardening;) which methods, however they may anſwer the intention for the preſent, yet will certainly greatly injure the trees, as muſt all violent amputations, which ſhould ever be avoided as much as poſſible on fruit-trees; and this, I am ſure, can never be wanted, where trees have been rightly planted, and regularly trained, while young.

The ſeaſon for pruning theſe trees is any time after the fruits are gathered, until the beginning of march; but the ſooner it is done after the fruit is gathered, the better, for reaſons already given for pruning of Peach-trees; though indeed the deferring of theſe until ſpring, where there are large quantities of trees to prune, is not ſo injurious to them, as to ſome tender fruits; but if the branches are regularly trained in ſummer, and the luxuriant ſhoots rubbed off, there will be little left to do to them in winter.

All the ſorts of Summer Pears will ripen very well either on ſtandards, dwarfs, or eſpaliers, as will all Autumn Pears upon dwarfs or eſpaliers; but, where a perſon is very curious in his fruit, I would always adviſe the planting them againſt eſpaliers, in which method they take up but little room in a garden, and, if they are well managed, appear very beautiful; and the fruit is larger and better taſted than thoſe produced on dwarfs, as has been already obſerved; but ſome of the Winter Pears muſt be planted againſt eaſt, ſouth-eaſt, or ſouth-weſt walls, otherwiſe they will not ripen well in England in bad ſeaſons.

But although this may be the caſe with ſome of the late Winter Pears in very bad ſeaſons, yet, in general, moſt ſorts of them will ripen extremely well in all warm ſituations, when they are planted in eſpalier, and the fruit will be better flavoured than that which grows againſt walls, and will keep much longer good; for, as the heat againſt walls which are expoſed to the ſun will be very great at ſome times, and at others there will be little warmth, all fruit which grow near them, will be haſtened unequally, and therefore are never ſo well flavoured as the ſame ſorts are which ripen in the open air; and all the fruit, which is ripened thus unequally, will decay much ſooner than thoſe which ripen gradually in the open air; therefore thoſe Winter Pears which grow in eſpalier, may be kept ſix weeks longer than thoſe which grow againſt walls, which is a very deſirable thing; for to have plenty of theſe fruit at a ſeaſon when it is very rare to find any other fruit to ſupply the table but Apples, is what all lovers of fruit muſt be greatly pleaſed to enjoy; which is what may be effected by planting many of the late ſorts in eſpalier, where, although the fruit will not be ſo well coloured as thoſe from the walls, yet they will be found exceeding good. When the Beſi de Chaumontelle came firſt to England, the trees were planted in eſpalier, and ſome of them not on a very good ſoil, or in a warm ſituation, and yet from theſe trees I have eaten this Pear in great perfection in april, and ſometimes it has kept till may; whereas, all thoſe which have been ſince planted againſt walls ripen their fruit by the beginning of november, and are generally gone by the middle of december; nor are the latter ſo well taſted as thoſe off the eſpaliers.

The Virgoleuſe and St. Germain, as alſo the Colmar, are eſteemed the moſt difficult ſorts to ripen their fruit, yet theſe I have eaten in great perfection from eſpaliers, and often from ſtandard-trees, where they grew upon a warm ſoil; but the fruit was much ſmaller on the ſtandard-trees than thoſe of the ſame ſorts which grew againſt walls or eſpaliers, but they were full as well flavoured, and ſome of theſe ſorts I have eaten good in april, which is two months later than they uſually keep; but yet I would not adviſe the planting theſe late Pears in ſtandard-trees, be-

cauſe they ſhould hang very late on the trees in autumn, at which ſeaſon the winds are generally very high; and theſe ſtandard-trees being much expoſed the fruit is often blown off the trees before they are ripe; and thoſe of them, which may hang on the trees, are frequently bruiſed by being forced againſt the branches by the winds, ſo that they ſeldom keep well. What I mentioned this for, is to prove, that theſe Pears will ripen very well without the aſſiſtance of a wall; ſo that if they are planted in eſpaliers where the trees are kept low, the fruit will not be ſo much expoſed to the ſtrong winds in autumn as thoſe on the ſtandards, therefore can be in no danger of the fruit coming to perfection; and as the trees in eſpaliers will be conſtantly pruned, and managed in the ſame manner as thoſe againſt walls, the fruit will be as large on thoſe trees; therefore, where a perſon has a warm ſituation and a kindly ſoil, I would not adviſe the being at an expence to build walls on purpoſe for Pears, but to plant them againſt eſpaliers: and where there is any one who is very curious in having plenty of theſe fruit, and will be at the expence to procure them, I ſhould adviſe having a ſufficient quantity of Reed mats made to fix up againſt the back of the eſpalier in the ſpring, when the trees are in bloſſom, which will ſcreen them from cold winds, and preſerve the tender fruit until they are paſt danger, when the Reeds may be taken down, and put under a ſhed to preſerve them from the weather; and if the autumn ſhould prove bad, theſe Reeds may be fixed up again, which will forward the ripening of the fruit, and alſo prevent the winds from blowing down, and bruiſing it.

But after the fruit is ſet and growing, there will be farther care neceſſary in order to have the fruit good; for it is not enough to have preſerved a good crop of fruit on the trees, and then leave them entirely to nature during the ſeaſon of their growth, but there will require ſome ſkill and attendance on the trees to help nature, or ſupply the deficiency of ſeaſons; for beſide the pruning and training trees in the manner before directed, there will alſo be wanting ſome management of their roots, according to the nature of the ſoil, and the difference of ſeaſons. In all ſtrong land, where the ground is apt to bind very hard in dry weather, the ſurface of the borders ſhould be now and then forked over to looſen the earth, which will admit the ſhowers and dews to penetrate and moiſten the ground, and be of great ſervice to the trees and fruit, and alſo prevent the growth of weeds. And if the ſoil is light and dry, and the ſeaſon ſhould prove hot and dry, there ſhould be large hollows made round the ſtems of the trees to hold water; and into each of theſe there ſhould be poured eight or nine pots of water, which ſhould be repeated once in a week or ten days during the months of june and july, if the ſeaſon ſhould continue dry. There ſhould alſo be ſome mulch laid over the ſurface of theſe hollows, to prevent the ſun and air from drying the ground. Where this is practiſed, the fruit will be kept conſtantly growing, and prove large and plump; whereas, if this is omitted, the fruit will often be ſmall, grow crooked, crack, and fall off from the trees. For if the fruit is once ſtinted in their growth, and rain ſhould fall plentifully after, it will occaſion a great quantity of fruit to fall off the trees, and thoſe which remain to ripen will not keep ſo long as thoſe which never receive any check in their growth; and it is from this cauſe, that ſome years the fruit in general decays before the uſual time. For after it has been for ſome time ſtinted in its growth, and then the ſeaſon proves favourable, whereby it receives a ſudden growth, it becomes ſo replete with juice, as to diſtend the veſſels too ſuddenly, ſo that they will not be firm, which occaſions their decay; therefore it is always beſt to keep the fruit conſtantly in a growing ſtate, whereby it will acquire a proper ſize, and be rendered better flavoured.

There will alſo be required ſome dreſſing to the ground near the fruit-trees; but this ſhould be laid on in autumn, after the trees are pruned. This dreſſing ſhould be different, according to the nature of the

ſoil; if the land is warm and dry, then the dreſſing ſhould be of very rotten dung, mixed with loam; and if this is mixed ſix or eight months before it is laid upon the borders, and three or four times turned over, it will be the better; as will alſo the mixture, if it is made with neat's or hog's dung, both which are colder than horſe-dung, ſo more proper for hot land. But in cold ſtiff land, rotten horſe dung, mixed with light ſandy earth, or ſea-coal aſhes, will be the moſt proper, as this will looſen the ground and add a warmth to it.

Theſe dreſſings ſhould be repeated every other year, otherwiſe the trees will not thrive ſo well, nor will the fruit be ſo good. For, notwithſtanding what many perſons have advanced to the contrary, yet experience is againſt them; for the fineſt fruit in England, both as to ſize and flavour, is produced on land which is the moſt dunged and worked. Therefore I would adviſe trenching the ground about the fruit-trees very well every winter, for I am ſure they will find it anſwer their expectations who ſhall practiſe this method. And where the ground in the quarters is will dreſſed and trenched, the fruit-trees will partake of the benefit; for as the trees advance in their growth, their roots are extended to a great diſtance from their ſtems; and it is chiefly from the diſtant roots that the trees are ſupplied with their nouriſhment: therefore dreſſing the borders only, will not be ſufficient for fruit-trees which are old.

In gathering of Pears, great regard ſhould be had to the bud which is formed at the bottom of the foot-ſtalk, for the next year's bloſſoms; which, by forcing off the Pear before it be mature, is many times ſpoiled; for while the fruit is growing, there is always a bud formed by the ſide of the foot-ſtalk upon the ſame ſpur, for the next year's fruit; but when the Pears are ripe, if they are gently turned upward, the foot-ſtalk will readily part from the ſpur, without injuring the bud.

The ſeaſon for gathering all Summer Pears is juſt as they ripen, for none of theſe will remain good above a day or two after they are taken from the tree; nor will many of the Autumn Pears keep good above ten days or a fortnight after they are gathered. But the winter fruits ſhould hang as long upon the trees as the ſeaſon will permit; for they muſt not receive the froſt, which will cauſe them to rot, and render their juices flat and ill taſted; but if the weather continue mild until the end of October, it will then be a good ſeaſon for gathering them in, which muſt always be done in dry weather, and when the trees are perfectly dry.

In doing this you ought carefully to avoid bruiſing them, therefore you ſhould have a broad flat baſket to lay them in as they are gathered; and when they are carried into the ſtore-room, they ſhould be taken out ſingly, and each ſort laid up in a cloſe heap on a dry place, in order to ſweat, where they may remain for ten days or a fortnight; during which time the windows ſhould be open to admit the air, in order to carry off all the moiſture which is perſpired from the fruit: after this, the Pears ſhould be taken ſingly, and wiped dry with a woollen cloth, and then packed up in cloſe baſkets, obſerving to put ſome Wheat ſtraw in the bottoms, and round the ſides of the baſkets, to prevent their bruiſing againſt the baſkets. And if ſome thick ſoft paper is laid double or treble all round the baſket, between the ſtraw and the Pears, this will prevent the Pears from imbibing the muſty taſte which is communicated to them by the ſtraw, when they are contiguous; which taſte often penetrates through the ſkin ſo ſtrongly, that when the fruit is pared, the taſte will remain. You ſhould alſo obſerve to put but one ſort of fruit into a baſket, leſt by their different fermentations, they ſhould rot each other; but if you have enough of one ſort to fill a baſket which holds two or three buſhels, it will be ſtill better. After you have filled the baſkets, you muſt cover them over with Wheat ſtraw very cloſe, firſt laying a covering of paper two or three times double over the fruit, and faſten them down; then place theſe baſkets in a cloſe room, where they may be kept dry and from froſt; but the leſs air is let into the room, the better the fruit will keep. It will be very neceſſary to fix a label to each baſket, denoting the ſort of fruit therein contained, which will ſave the trouble of opening them, whenever you want to know the ſorts of fruit; beſides, they ought not to be opened before their ſeaſon to be eaten, for the oftener they are opened and expoſed to the air, the worſe they will keep. I do not doubt but this will be objected to by many, who imagine fruit cannot be laid too thin; for which reaſon, they make ſhelves to diſpoſe them ſingly upon, and are very fond of admitting freſh air, whenever the weather is mild, ſuppoſing it very neceſſary to preſerve the fruit; but the contrary of this is found true, by thoſe perſons who have large ſtocks of fruit laid up in their ſtore-houſes in London, which remain cloſely ſhut up for ſeveral months, in the manner before related; and when theſe are opened, the fruit is always found plumper and ſounder than any of thoſe fruits which were preſerved ſingly upon ſhelves, whoſe ſkins are always ſhrivelled and dry. For (as Mr. Boyle obſerves) the air is the cauſe of putrefaction; and, in order to prove this, that honourable perſon put fruits of ſeveral kinds into glaſſes where the air was exhauſted, in which places they remained ſound for ſeveral months, but, upon being expoſed to the air, rotted in a very ſhort time after; which plainly ſhews the abſurdity of the common method now uſed, to preſerve fruit.

All the ſorts of Apples are propagated by grafting or budding upon the ſtocks of the ſame kind, for they will not take upon any other ſort of fruit tree. In the nurſeries there are three ſorts of ſtocks generally uſed to graft Apples upon; the firſt are called free ſtocks; theſe are raiſed from the kernels of all ſorts of Apples indifferently, and ſometimes they are alſo termed Crab ſtocks; for all thoſe trees which are produced from the ſeeds before they are grafted, are termed Crabs without any diſtinction; but, I ſhould always prefer ſuch ſtocks as are raiſed from the kernels of Crabs, where they are preſſed for verjuice; and I find ſeveral of the old writers on this ſubject of the ſame mind. Mr. Auſten, who wrote above a hundred years ago, ſays, "The ſtock which he accounts "beſt for Apple grafts is the Crab, which is better "than ſweeter Apple-trees to graft on, becauſe they "are uſually free from canker, and will become very "large trees; and, I conceive, will laſt longer than "ſtocks of ſweeter Apples, and will make fruits "more ſtrong and hardy to endure froſt;" and it is very certain, that by frequently grafting ſome ſorts of Apples upon free ſtocks, the fruits have been rendered leſs firm and poignant, and of ſhorter duration.

The ſecond ſort of ſtock is the Dutch Paradiſe Apple or Creeper; theſe are deſigned to ſtint the growth of the trees, and keep them within compaſs for dwarfs or eſpaliers.

The third ſort is the Paradiſe Apple, which is a very low ſhrub, and only proper for trees which are kept in pots, by way of curioſity, for theſe do not continue long.

Some perſons have made uſe of Codlin ſtocks for grafting Apples, in order to ſtint their growth; but as theſe are commonly propagated by ſuckers, I would by no means adviſe the uſing them; nor would I chuſe to raiſe the Codlin-trees from ſuckers, but rather graft them upon Crab ſtocks, which will cauſe the fruit to be firmer, laſt longer, and have a ſharper flavour; and theſe trees will laſt much longer ſound, and never put out ſuckers, as the Codlins always do, which, if not conſtantly taken off, will weaken the trees, and cauſe them to canker: and it is not only from the roots, but from the knots of their ſtems, there are generally a great number of ſtrong ſhoots produced, which fill the trees with uſeleſs ſhoots, and render them unſightly, and the fruit ſmall and crumpled.

The method of raiſing ſtocks from the kernels of Crabs, or Apples, is, to procure them where they are preſſed for verjuice or cyder, and after they are cleared of the pulp, they may be ſown upon a bed of light earth, covering them over about half an inch

thick with the ſame light earth; theſe may be ſown in november or december, where the ground is dry, but in wet ground, it will be better to defer it till february; but then the ſeeds ſhould be preſerved in dry ſand, and kept out of the reach of vermin, for if mice or rats can get at them, they will devour the ſeeds; there ſhould alſo be care taken of the ſeeds, when they are ſown, to protect them from theſe vermin, by ſetting traps to take them, &c. In the ſpring, when the plants begin to appear, they muſt be carefully weeded, and if the ſeaſon ſhould prove dry, it will be of great ſervice to water them two or three times a week; and, during the ſummer, they muſt be kept clean from weeds, which, if ſuffered to grow, will ſoon over-top the plants, and ſpoil their growth; if theſe thrive well, they will be fit to tranſplant into the nurſery the october following, at which time the ground ſhould be carefully digged, and cleanſed from the roots of all bad weeds; then the ſtocks ſhould be planted in rows three feet aſunder, and the plants one foot diſtance in the rows, cloſing the earth pretty faſt to their roots; when the ſtocks are tranſplanted out of the ſeed-bed, the firſt autumn after ſowing, they need not be headed, but where they are inclined to ſhoot downward, the tap root muſt be ſhortened, in order to force out horizontal roots; if the ground is pretty good in which theſe ſtocks are planted, and the weeds conſtantly cleared away, the ſtocks will make great progreſs, ſo that thoſe which are intended for dwarfs, may be grafted the ſpring twelve months after they are planted out of the ſeed-bed; but thoſe which are deſigned for ſtandards will require two or three years more growth, before they will be fit to graft, by which time they will be upward of ſix feet high. The other neceſſary work to be obſerved in the culture of theſe trees, while they remain in the nurſery, being exhibited under the article of NURSERY, I ſhall not repeat in this place.

I ſhall next treat of the manner of planting ſuch of theſe trees as are deſigned for eſpaliers in the kitchen-garden, where, if there is an extent of ground, it will be proper to plant, not only ſuch ſorts as are for the uſe of the table, but alſo a quantity of trees to ſupply the kitchen; but where the kitchen-garden is ſmall, the latter muſt be ſupplied from ſtandard-trees, either from the orchard, or wherever they are planted; but as many of theſe kitchen Apples are large, and hang late in the autumn upon the trees, they will be much more expoſed to the ſtrong winds on ſtandard trees than in eſpaliers, whereby many of the fruit will be blown down before they are ripe, and others bruiſed, ſo as to prevent their keeping; therefore where it can be done, I ſhould always prefer the planting them in eſpaliers.

The diſtance which I ſhould chuſe to allow theſe trees, ſhould not be leſs than thirty feet, for ſuch ſorts as are of moderate growth (if upon Crab or free ſtocks:) but the larger growing ſorts ſhould not be allowed leſs room than thirty-five or forty feet, which will be found full near enough, if the ground is good, and the trees properly trained; for as the branches of theſe trees ſhould not be ſhortened, but trained at their full length, ſo in a few years they will be found to meet. Indeed, at the firſt planting, the diſtance will appear ſo great to thoſe perſons who have not obſerved the vigorous growth of theſe trees, that they will ſuppoſe they never can extend their branches ſo far, as to cover the eſpalier; but if theſe perſons will but obſerve the growth of ſtandard-trees of the ſame kinds, and ſee how wide their branches are extended on every ſide, they may be ſoon convinced, that as theſe eſpalier-trees are allowed to ſpread but on two ſides, they will of courſe make more progreſs, as the whole nouriſhment of the root will be employed in theſe ſide branches, than where there is a greater number of branches on every ſide of the tree, which are to be ſupplied with the ſame nouriſhment.

The next thing to be obſerved is the making choice of ſuch ſorts of fruits as grow nearly alike, to plant in the ſame eſpalier. This is of great conſequence, becauſe of the diſtance they are to be placed, otherwiſe thoſe ſorts which make the largeſt ſhoots, may be allowed leſs room to ſpread than thoſe of ſmaller growth; beſide, when all the trees in one eſpalier are nearly equal in growth, they will have a better appearance than when ſome are tall, and others ſhort; but for the better inſtruction of thoſe perſons who are not converſant in theſe things, I ſhall divide the ſorts of Apples into three claſſes according to their different growths.

Largeſt growing tree.

All the ſorts of Pearmains.
Kentiſh Pippin.
Holland Pippin.
Monſtrous Renette.
Royal Ruſſet.
Wheeler's Ruſſet.
Pile's Ruſſet.
Nonpareil.
Violet Apple.

Middle growing tree.

Margaret Apple.
Golden Renette.
Aromatic Pippin.
Embroidered Apple.
Renette Griſe.
White Renette.
Codlin.

Smalleſt growing tree.

Quince Apple.
Tranſparent Apple.
Golden Pippin.
Pomme d'Api.
Fenouillet, or Anis Apple.

N. B. Theſe are all ſuppoſed to be graſted on the ſame ſort of ſtocks.

If theſe Apples are grafted upon Crab ſtocks, I would willingly place them at the following diſtance from each other, eſpecially where the ſoil is good, viz. the largeſt growing trees at forty feet, the middle growing at thirty feet, and the ſmall growing at twenty-five feet, which, from conſtant experience, I find to be full near enough; for in many places, where I have planted theſe trees at twenty-four feet diſtance, they have ſhot ſo ſtrong, as that in ſeven years their branches have met; and in ſome places where every other tree has been taken up, the branches have almoſt joined in ſeven years after; therefore it will be much the better way to plant theſe trees at a proper diſtance at firſt, and between theſe to plant ſome Dwarf Cherries, Currants, or other ſorts of fruit, to bear for a few years, which may be cut away when the Apple-trees have extended their branches to them; for when the Apple-trees are planted nearer together, few perſons care to cut down the trees, when they are fruitful, ſo that they are obliged to uſe the knife, ſaw, and chiſel, more than is proper for the future good of the trees; and many times, where perſons are inclinable to take away part of their trees, the diſtances will be often ſo irregular (where there was not this conſideration in their firſt planting,) as to render the eſpalier unſightly.

When the trees are upon the Dutch Dwarf ſtock, the diſtance ſhould be for the larger growing trees thirty feet, for thoſe of middle growth twenty-five, and the ſmalleſt twenty feet, which will be found full near where the trees thrive well.

The next is the choice of the trees, which ſhould not be more than two years growth from the graft, but thoſe of one year ſhould be preferred; you ſhould alſo be careful, that their ſtocks are young, ſound, and ſmooth, free from canker, and which have not been cut down once or twice in the nurſery; when they are taken up, all the ſmall fibres ſhould be entirely cut off from their roots, which, if left on, will turn mouldy and decay, ſo will obſtruct the new fibres,

fibres, which will ſoon puſh out, in their growth; the extreme part of the roots muſt alſo be ſhortened, and all bruiſed roots cut off; and if there are any miſplaced roots which croſs each other, they ſhould alſo be cut away. As to the pruning of the head of theſe trees, there need be nothing more done than to cut off any branches which are ſo ſituated, as that they cannot be trained to the line of the eſpalier: in the planting, there muſt be care taken not to place their roots too deep in the ground, eſpecially if the ſoil is moiſt, but rather raiſe them on a little hill, which will be neceſſary to allow for the raiſing of the borders afterward. The beſt ſeaſon for planting theſe trees (in all ſoils which are not very moiſt) is, from october, to the middle or latter end of november, according as the ſeaſon continues mild; but ſo ſoon as the leaves fall, they may be removed with great ſafety. After the trees are planted, it will be proper to place down a ſtake to each tree, to which the branches ſhould be faſtened, to prevent the winds from ſhaking or looſening their roots, which will deſtroy the young fibres; for when theſe trees are planted pretty early in autumn, they will very ſoon puſh out a great number of new fibres, which, being very tender, are ſoon broken, by the wind ſhaking the trees, whereby they are greatly injured. If the winter ſhould prove ſevere, it will be proper to lay ſome rotten dung, tanners bark, or ſome other ſort of mulch about their roots, to prevent the froſt from penetrating the ground, which might damage theſe tender fibres; but I would not adviſe the laying this mulch before the froſt begins, for if it is laid over the ſurface of the ground about their roots, ſoon after the trees are planted (as is often practiſed,) it will prevent the moiſture entering the ground, and do much more harm than good to the trees.

The following ſpring, before the trees begin to puſh, there ſhould be two or three ſhort ſtakes put down on each ſide every tree, to which the branches ſhould be faſtened down as horizontally as poſſible, never cutting them down, as is by ſome practiſed, for there will be no danger of their putting out branches enough to furniſh the eſpalier, if the trees are once well eſtabliſhed in their new quarters.

In the pruning of theſe trees, the chief point is, never to ſhorten any of the branches, unleſs there is an abſolute want of ſhoots to fill the ſpaces of the eſpalier; for where the knife is much uſed, it only multiplies uſeleſs ſhoots, and prevents their fruiting; ſo that the beſt method to manage theſe trees is, to go over them three or four times in the growing ſeaſon, and rub off all ſuch ſhoots as are irregularly produced, and train the others down to the ſtakes in the poſition they are to remain: if this is carefully performed in ſummer, there will be little left to be done in the winter, and by bending their ſhoots from time to time, as they are produced, there will be no occaſion to uſe force to bring them down, nor any danger of breaking the branches. The diſtance which theſe branches ſhould be trained from each other, for the largeſt ſorts of fruits, ſhould be about ſeven or eight inches, and for the ſmaller four or five. If theſe plain inſtructions are followed, it will ſave much unneceſſary labour of pruning, and the trees will, at all times, make a handſome appearance; whereas when they are ſuffered to grow rude in ſummer, there will be much greater difficulty to bring down their ſhoots, eſpecially if they are grown ſtubborn, when it may become neceſſary to ſlit the branches to make them pliable. All the ſorts of Apples produce their fruit upon curſons, or ſpurs, ſo that theſe ſhould never be cut off, for they will continue fruitful a great number of years.

The method of making the eſpaliers having been already exhibited under that article, I need not repeat it here, but only obſerve, that it will be beſt to defer making the eſpalier till the trees have had three or four years growth; for before that time, the branches may be ſupported by a few upright ſtakes, ſo that there will be no neceſſity to make the eſpalier, until there are ſufficient branches to furniſh all the lower part.

I ſhall now treat of the method to plant orchards, ſo as to have them produce the greateſt profit. And firſt, in the choice of the ſoil and ſituation for an orchard: the beſt ſituation for an orchard is, on the aſcent of the gentle hills, facing the ſouth, or ſouth-eaſt; but this aſcent muſt not be too ſteep, leſt the earth ſhould be waſhed down by haſty rains. There are many perſons who prefer low ſituations at the foot of hills, but I am thoroughly convinced from experience, that all bottoms where there are hills on each ſide, are very improper for this purpoſe; for the air is drawn down into theſe vallies in ſtrong currents, which, being pent in renders theſe bottoms much colder than the open ſituations; and during the winter and ſpring, theſe bottoms are very damp and unhealthy to all vegetables; therefore the gentle riſe of a hill, fully expoſed to the ſun and air, is by much the beſt ſituation. As to the ſoil, a gentle hazel loam, which is eaſy to work, and that does not detain the wet, is the beſt; if this happens to be three feet deep, it will be better for the growth of the trees, for although theſe trees will grow upon very ſtrong land, yet they are ſeldom ſo thriving, nor are their fruit ſo well flavoured, as thoſe which grow on a gentle ſoil; and on the other hand, theſe trees will not do well upon a very dry gravel or ſand, therefore thoſe ſoils ſhould never be made choice of for orchards.

The ground intended to be planted ſhould be well prepared the year before, by ploughing it thoroughly, and if ſome dung is laid upon it the year before, it will be of great ſervice to the trees; if in the preceding ſpring a crop of Peas or Beans is planted on the ground (provided they are ſown or planted in rows, at a proper diſtance, ſo as that the ground between them is horſe-hoed,) it will deſtroy the weeds, and looſen the ground, ſo that it will be a good preparation for the trees, for the earth cannot be too much wrought, or pulverized for this purpoſe: theſe crops will be taken off the ground long before the ſeaſon for planting theſe trees, which ſhould be as ſoon as poſſible performed when the trees begin to ſhed their leaves.

In chuſing the trees, I would adviſe the taking ſuch as are but of two years growth from the graft, and never to plant old trees, or ſuch as are grafted upon old ſtocks, for it is loſing of time to plant theſe; young trees being always more certain to grow, and make a much greater progreſs than thoſe which are old. As to pruning the roots, it muſt be done in the ſame manner as has been already directed for the eſpalier-trees; and in pruning their heads, little more is neceſſary than to cut out ſuch branches as are ill placed, or that croſs each other; for I do not approve the heading of them down, as is by ſome often practiſed to the loſs of many of their trees.

The diſtance which theſe trees ſhould be planted, where the ſoil is good, muſt be fifty or ſixty feet; and where the ſoil is not ſo good, forty feet may be ſufficient; but nothing can be of worſe conſequence, than the crowding trees too cloſe together in orchards. And although there may be ſome who may imagine this diſtance too great, yet I am ſure, when they have thoroughly conſidered the advantages attending this practice, they will agree with me. Nor is it my own opinion in this affair, for in many of the old writers on this ſubject, there is often mention made of the neceſſity for allowing a proper diſtance to the fruit-trees in orchards, particularly Auſten, upon planting before quoted, who ſays, "He ſhould chuſe to pre-"ſcribe the planting theſe trees fourteen or ſixteen "yards aſunder; for both trees and fruits have many "great advantages, if planted a good diſtance one "from another." One advantage he mentions is, "The ſun refreſhes every tree, the roots, body, and "branches, with the bloſſoms and fruits; whereby "trees bring forth more fruit, and thoſe fairer and "better." Another advantage he mentions is, "That "when trees are planted at a large diſtance, much "profit may be made of the ground under and about "theſe trees, by cultivating garden-ſtuff, commo-"dious as well for ſale as houſekeeping; as alſo "Gooſeberries, Raſpberries, Currants, and Straw-"berries,

" berries, may be there planted." Again he ſays, " When trees have room to ſpread, they will grow " very large and great; and the conſequences of that " will be, not only multitudes of fruits, but alſo long " laſting, and theſe two are no ſmall advantages." For, ſays he, " Men are miſtaken, when they ſay, " the more trees in an orchard, the more fruits; for " one or two large trees which have room to ſpread, " will bear more fruits than ſix or ten (it may be) of " thoſe that grow near together, and crowd one an- " other." Again he ſays, " Let men but obſerve, " and take notice of ſome Apple-trees, that grow a " great diſtance from other trees, and have room " enough to ſpread both their roots and branches, " and they ſhall ſee, that one of thoſe trees (being " come to full growth) hath a larger head, and more " boughs and branches, than (it may be) four, or ſix, " or more, of thoſe which grow near together, al- " though of the ſame age."

And Mr. Lawſon, an ancient planter, adviſes to plant Apple-trees twenty yards aſunder. As the two authors above quoted have written the beſt upon this ſubject, and ſeem to have had more experience than any of the writers I have yet ſeen, I have made uſe of them as authorities to confirm what I have advanced; though the fact is ſo obvious to every perſon who will make the leaſt reflection, that there needs no proof.

When the trees are planted, they ſhould be ſtaked, to prevent their being ſhaken, or blown out of the ground by ſtrong winds; but in doing this, there ſhould be particular care taken, to put either ſtraw, haybands, or woollen cloth, between the trees and the ſtakes, to prevent the trees from being rubbed and bruiſed, by the ſhaking againſt the ſtakes, for if their bark ſhould be rubbed off, it will occaſion ſuch great wounds, as not to be healed over in ſeveral years, if they ever recover it.

If the winter ſhould prove very ſevere, it will be proper to cover the ſurface of the ground about their roots with ſome mulch, to prevent the froſt from penetrating the ground, which will deſtroy the young fibres; but this mulch ſhould not be laid on too ſoon, as has been before mentioned, leſt the moiſture ſhould be prevented from ſoaking down to the roots of the trees, nor ſhould it lie on too long in the ſpring for the ſame reaſon; but where perſons will be at the trouble to lay it on in froſty weather, and remove it again after the froſt is over, that the wet in february may have free acceſs to the roots of the trees it will do good; and if march ſhould prove dry, with ſharp north or eaſt winds, which often happens, it will be proper to cover the ground again with the mulch, to prevent the winds from penetrating and drying the ground, and will be of ſingular ſervice to the trees. But I am aware, that this will be objected to by many, on account of the trouble, which may appear to be great; but when it is conſidered, how much of this buſineſs may be done by a ſingle perſon in a ſhort time, it can have little force, and the benefit which the trees will receive by this management, will greatly recompenſe the trouble and expence.

As theſe trees muſt be conſtantly fenced from cattle, it will be the beſt way to keep the land in tillage for ſome years, that by conſtant ploughing or digging the ground, the roots of the trees will be more encouraged, and they will make the more progreſs in their growth: but where this is done, whatever crops are ſown or planted, ſhould not be too near the trees, leſt the nouriſhment ſhould be drawn away from the trees; and as in the ploughing of the ground where it is ſo tilled, there muſt be care taken not to go too near the ſtem of the trees, whereby their roots would be injured, or the bark of their ſtems rubbed off, ſo it will be of great ſervice to dig the ground about the trees where the plough does not come, every autumn, for five or ſix years after planting, by which time their roots will have extended themſelves to a greater diſtance.

It is a common practice in many parts of England, to lay the ground down for paſture, after the trees are grown pretty large in their orchards; but this is by no means adviſeable, for I have frequently ſeen trees of above twenty years growth, almoſt deſtroyed by horſes, in the compaſs of one week; and if ſheep are put into orchards, they will conſtantly rub their bodies againſt the ſtems of the trees, and their greaſe ſticking to the bark, will ſtint their growth, and in time will ſpoil them; therefore wherever orchards are planted, it will be much the better method to keep the ground ploughed or dug annually, and ſuch crops put on the ground as will not draw too much nouriſhment from the trees.

In pruning of orchard-trees, nothing more ſhould be done, but to cut out all thoſe branches which croſs each other, and, if leſt, would rub and tear off the bark, as alſo decayed branches, but never ſhorten any of their ſhoots. If ſuckers, or ſhoots from their ſtems, ſhould come out, they muſt be entirely taken off annually; and when any branches are broken by the wind, they ſhould be cut off, either down to the diviſion of the branch, or cloſe to the ſtem from whence it was produced; the beſt time for this work is in november, for it ſhould not be done in froſty weather, nor in the ſpring, when the ſap begins to be in motion.

The beſt method to keep Apples for winter uſe is, to let them hang upon the trees until there is danger of froſt, and to gather them in dry weather, laying them in large heaps to ſweat for three weeks or a month; afterwards look them over carefully, taking out all ſuch as have appearance of decay, wiping all the ſound fruit dry, and pack them up in large oil-jars, which have been thoroughly ſcalded and dry, ſtopping them down cloſe to exclude the external air: if this is duly obſerved, the fruit will keep ſound a long time, and their fleſh will be plump; for when they are expoſed to the air, their ſkins will ſhrink, and their pulp will be ſoft.

[It has been lately made evident, particularly by the experiments and curious remarks of T. A. Knight, Eſq; that thoſe varieties of the Apple, of which the original trees had periſhed from old age, could not be made to grow to any purpoſe. The grafts, he ſays, grow well for two or three years; but after that become cankered and moſſy. When he firſt obſerved the unhealthy ſtate of all the young trees of theſe kinds, he ſuſpected that it aroſe from the uſe of diſeaſed grafts taken from old trees; and that he ſhould be able to propagate all the valuable varieties by buds taken from young newly grafted trees: but to remove ſtill farther every probability of defect which might be communicated from the old trees, he inſerted the young ſhoots and buds, taken from newly grafted trees, on other young ſtocks, and repeated this proceſs ſix times in as many years, each year taking his grafts and buds from thoſe inſerted in the year preceding. Stocks of different kinds were alſo uſed; ſome were double grafted, others were obtained from trees which grew from cuttings, and others from the ſeeds of each kind afterwards inſerted in them, under the idea that there might be ſomething congenial to the fruits in theſe. The grafts grew tolerably, and equally in all; but there was a want of hardneſs and elaſticity in the wood, and at the end of three or four years all began to canker. This diſeaſe is always found in thoſe varieties which have been long in cultivation; and in theſe it annually becomes more deſtructive, and evidently ariſes from the age of the variety; but it often appears to be hereditary. A gravelly or wet ſoil, a cold preceding ſummer, or a high expoſed ſituation, add much to its virulence. It is moſt fatal to young free-growing trees of old varieties; and even the ſtrong ſhoots of theſe will be totally deſtroyed by it, when the old trees growing in the ſame orchard, and from which the grafts had been taken, were nearly free from the diſeaſe. The young ſtocks, by affording the grafts a preternatural abundance of nouriſhment, ſeem to bring on the diſeaſe; and tranſplanting, or a heavy crop of fruit, which check the growth of the tree, diminiſh its diſpoſition to canker. In middle-aged trees of very old varieties a ſucceſſion of young ſhoots is annually produced by the vigour of the ſtock, and deſtroyed again in the ſucceeding winter: the quantity of fruit theſe produce

is in conſequence very ſmall. In this diſeaſe ſomething more than a mere extinction of vegetable life appears to take place. The internal bark bears marks of ſomething ſimilar to eroſion; and this is probably the original ſeat of the diſeaſe, though the wood of the annual ſhoots is ſoon tinged to the centre. The canker does not appear to be ever a primary or merely local diſeaſe, but to ariſe from the morbid habit of the plant, and to be incurable by any topical application.

Being after much unſucceſsful experience ſatisfied, that thoſe varieties of the Apple, of which the original trees had long periſhed from old age, could not be made to grow; Mr. Knight ſuſpected, that grafts taken from very young ſeedling trees, not yet in a bearing ſtate, could not by any means be made to produce fruit. Having taken cuttings from ſome of theſe of two years old, he inſerted them in ſtocks of twenty, which had already produced fruit. He afterwards frequently tranſplanted, and took every means in his power to make them produce bloſſoms; but though they grew in rich ground, which probably tended to accelerate their maturity, he did not ſucceed till the ſeedling trees were twelve years old, the age at which they uſually produce fruit; and then other grafts of the ſame kind, which had been inſerted but three years before, readily bloſſomed. Other cuttings were inſerted in very old ſtocks, which were regrafted; theſe grew with exceſſive vigour, but did not produce bloſſoms ſo ſoon as the others.

From the reſult of theſe experiments, and from the general failure of every attempt to propagate every old variety of the Apple, Mr. Knight thinks himſelf juſtified in the concluſion, that all Apples, however propagated from the ſame ſtock, partake in ſome degree of the ſame life, and will attend it in the habits of their youth, their maturity and decay; though they will not be any way affected by any incidental injuries the parent tree may ſuſtain, after they are detached from it. The roots however, and the trunk adjoining them, appear to poſſeſs in all trees a greater degree of durability than the bearing branches, having a power of producing new ones, when the old have been deſtroyed by accident, or even by old age: and grafts taken from ſcions, which have ſprung out of the trunks of old ungrafted Apple and Pear trees, will grow with much greater luxuriance than thoſe taken at the ſame time from the extremities of the bearing branches. The former in their growth aſſume the appearance of young ſeedling ſtocks, and the ſhoots of the Pear are, like thoſe covered with thorns. Thoſe propagated from the bearing branches frequently produce fruit the ſecond year, but the others remain long unproductive. It appears therefore extremely probable, that ſuch trees as the Walnut and Mulberry, which do not produce fruit in leſs than twenty years, might be rendered fruitful in one third of that time, by being grafted with cuttings taken from the productive branches of an old tree.

Since then the valuable varieties of the Apple and Pear cannot be continued for ever, till new varieties can be raiſed equally valuable, let us ſee whether the duration of the old ones may not be conſiderably prolonged by art.

Now the life of every tree appears to be greatly prolonged, when its branches are frequently taken off; and there is not the leaſt doubt but that the life of an Apple or Pear might be prolonged to thrice its natural period, by robbing it of its branches as ſoon as the qualities of its fruit are known; and retaining it as a pollard, or rather as a ſtool in a coppice, which is felled at regular periods: for theſe are known to poſſeſs a much greater degree of durability, than the ſame kind of tree left in the natural ſtate; and to produce a vigorous ſucceſſion of branches during ſeveral centuries. It is however probable that after a certain period, each effort of nature will be inferior to the preceding: for timber trees which ſpring from old ſtools, are obſerved to attain only a ſmall ſtature, with an early maturity and decay. Should any valuable variety of the Apple be retained in the ſtate here deſcribed, its branches ſhould be taken off every third or fourth year, and uſed for grafts, and it ſhould never be ſuffered to produce fruit or bloſſoms. Under this mode of treatment, there is little doubt but that the ſame variety might be propagated through many centuries.

It appears alſo probable that the latter period of the exiſtence of the Apple-tree would be conſiderably prolonged in a ſouthern climate, for all the old varieties ſucceed beſt in warm ſituations, and the moſt diſeaſed flouriſh with the greateſt vigour when trained to a ſouth wall. This mode of culture might probably be adopted with much advantage, when new varieties are to be obtained from ſeed; and the production of theſe muſt be the firſt thing to engage the attention of the planter of the preſent day [f].

For this purpoſe, Mr. Marſhall recommends to elect among the varieties, individuals of the higheſt flavour: to ſow the ſeeds in a highly enriched ſeed-bed: to ſelect from among the ſeedlings the plants wherein the wood and leaves have the beſt appearance: to tranſplant theſe into a rich deep ſoil, in a good ſituation, at due diſtances: letting them remain in this nurſery, until they begin to bear.

With the ſeeds of the faireſt, richeſt and beſt-flavoured fruit, repeat this proceſs: and at the ſame time, or in due ſeaſon, engraft the wood which produced this fruit, on that of the richeſt, ſweeteſt, beſt-flavoured Apple: repeating this operation, and tranſferring the ſubject under improvement, from one tree and ſort to another, as richneſs, flavour or firmneſs may require. Continuing this double mode of improvement, until the deſired fruit be obtained [g].

Such trials are doubly worth making; but it would be difficult to ſay what might be the iſſue of them until they are actually made.

When Mr. Knight began to ſuſpect that his endeavours to propagate the old fruits would not be ſucceſsful, he ſelected ſeeds of ſome of the beſt kinds, with an intention to propagate new ones: but he ſoon found that many of the young plants, particularly thoſe from the Golden Pippin, were nearly as much diſeaſed as the trees which produced them. He ſeveral times raiſed three or four plants from ſeeds taken from one Apple, and when this had been produced by a diſeaſed tree, he had not only as many varieties as there were ſeeds, but ſome were much diſeaſed, and others apparently healthy; though the ſeeds were ſown in the ſame ſoil, and the plants afterwards grew within two feet of each other in the nurſery. Grafts having been inſerted from each, retained the habits of the tree from which they were taken. Few, however, if any, appeared to poſſeſs a ſufficient degree of vigour to promiſe much ſucceſs in their cultivation, except in very favourable ſituations, even ſhould their fruit be good.

Having before obſerved that all the old fruits were free from diſeaſe when trained to a ſouth wall, Mr. Knight thought it not improbable that ſeedling plants raiſed from them would be equally healthy; and that their bloſſoms being expanded before thoſe of the neighbouring orchards, they would not be impregnated by the farina of inferior kinds. With a view to try this, he prepared ſtocks of the beſt kind of Apple which could be propagated by cuttings, planted them againſt a ſouth wall, in extremely rich mould, and graſted them with the Stire, Golden Pippin, and a few other fruits, whoſe time of ripening ſuited the ſituation in which he wiſhed to plant. In the courſe of the enſuing winter the young trees were dug up, and their roots having been retrenched, were planted again in the ſame places. This mode of treatment had the deſired effect of making them produce bloſſoms at two years old. He ſuffered only one or two fruits to remain on each tree, which in conſequence attained nearly three times their common ſize, with a very high degree of maturity and perfection; and the appearance of the plants he raiſed from their ſeeds ſo much excelled any he had formerly obtained from the ſame fruits taken from the orchard, that he thinks he can confidently recommend the method he adopted.

[f] Treatiſe on the culture of the Apple and Pear, p. 10. to 23.
[g] Glouceſterſh. 4. 249.

He had choſen fruits poſſeſſing excellencies and defects of oppoſite kinds, with a wiſh to ſee, either through the induſtry of bees or his own, the effects of a proceſs ſimilar to what is called by breeders of animals, croſſing the breed.

A few days before the bloſſoms expanded, he opened the petals and deſtroyed the males in all the bloſſoms which he ſuffered to remain of one kind, taking great care to leave the females uninjured: and when theſe bloſſoms were fully expanded, he impregnated half of them with farina taken from another kind of fruit, leaving the other half to the care of the bees, which collected about them in great numbers. Every fruit which he impregnated grew rapidly, whilſt half of thoſe on the other tree, which remained in their natural ſtate failed, with every one of thoſe left to the care of the bees. Whence we may conclude that theſe inſects are not ſo good carriers of the farina of plants, as is generally ſuppoſed by naturaliſts. The plants he obtained from the fruits on which this experiment was made, were certainly the moſt promiſing of any, but whether they will remain free from hereditary diſeaſe and debility or not, remains to be proved. Every ſeed, though taken from the ſame Apple furniſhes a diſtinct variety; and ſome of theſe will grow with more luxuriance than others, and the fruits produced by the different plants will poſſeſs different degrees of merit; but an eſtimate may be made of their good and bad qualities at the concluſion of the firſt ſummer, by the reſemblance the leaves bear to the highly cultivated or wild kinds. The plants whoſe buds in the annual wood are full and prominent are uſually more productive than thoſe whoſe buds are ſmall and ſhrunk into the bark; but their future produce will depend much on the power the bloſſoms poſſeſs of bearing cold, and this power varies in the different varieties, and can only be known from experience. Thoſe which produce leaves and bloſſoms rather early in the ſpring are generally to be preferred, for though they are more expoſed to injury from froſt, they leſs frequently ſuffer from the attacks of inſects, the more common cauſe of failure.

The Apple being moſt eaſily propagated by grafting, the means of obtaining proper Stocks muſt be among the firſt things to occupy the attention of the planter. A preference has generally, and juſtly been given to thoſe raiſed from the ſeeds of the Crab, as being more hardy and durable than thoſe produced from the Apple. The tree from which the ſeeds are taken ſhould be large and of free growth; and rather in a growing ſtate than one of maturity or decay. Crab trees that ſtand in cultivated grounds generally grow more freely, and attain a larger ſtature than thoſe in woods, and therefore appear to claim a preference. The ſeeds ſhould be taken from the fruit before it is ground, and ſown in beds of rich mould an inch deep. From theſe the plants ſhould be removed in the following autumn to the nurſery, and planted in rows at three feet diſtance from each other, and eighteen inches between each plant. Being protected from cattle and hares, they may remain here till they become large enough to be planted out; but the ground muſt be regularly worked and kept free from weeds.

The Apple tree ſucceeds beſt in ſituations which are neither high nor remarkably low. In the former its bloſſoms are frequently injured by cold winds, and in the latter by ſpring-froſts, particularly when the trees are planted in the loweſt part of a confined valley. A ſouth or ſouth-eaſt aſpect is generally preferred, on account of the turbulence of the weſt wind, and the coldneſs of the north wind; but Orchards ſucceed well in all, and where the violence of the weſt-wind is broken by an intervening riſe of ground, a ſouth-weſt aſpect will be found equal to any. The trees attain their largeſt ſtature in a deep ſtrong loam, but will grow well in all rich ſoils, which are neither very ſandy nor wet. They are ſaid to do beſt where the ground is much trod and manured by cattle in winter. Places where old Apple trees have grown are eſteemed unfavourable to young ones; and where fruit trees are kept near a houſe for convenience; Pears and Apples or other different ſorts ſhould be made to ſucceed each other.

Blights are produced by a variety of cauſes; by inſects, by an exceſs of heat or cold, of drought or moiſture; for theſe neceſſarily derange if they do not deſtroy the delicate organization of the bloſſom: but the common opinion that they ariſe from ſome latent noxious quality in the air, or from lightning, ſeems to be totally unfounded. The term *Blight* is frequently uſed by the gardener and farmer, without any defined idea being annexed to it. If the leaves of their trees be eaten by the caterpillar, or contracted by the aphis or plant-louſe; if the bloſſoms fall from the ravages of inſects, or without any apparent cauſe, the trees are ſaid to be blighted: and if an eaſt wind happen to have blown, the inſects, or at leaſt their eggs, whatever be their ſize, are ſuppoſed to have been brought by it. This opinion has probably been taken up from the hazy appearance of the air, which uſually accompanies warm days and froſty nights with a north-eaſt wind in the ſpring. This weather is injurious to the bloſſom of every tree, and particularly ſo to that of the Apple; for the warmth of the day hatches the eggs of the inſect that breeds in it, whilſt the coldneſs of the night, by checking the progreſs of the ſap, retains the bloſſom in its half-expanded ſtate, to form a nidus for it. This inſect, which aſſumes the winged ſtate in july, is a ſmall brown beetle, and it then probably lays thoſe eggs on the trees, which, if the ſucceeding ſeaſon be unfavourable, prove deſtructive of the future crop of fruit. The leaves and bloſſoms are ſometimes deſtroyed by numerous hoſts of caterpillars, ſome kinds of which become flies in the ſummer and autumn, others in the ſucceeding ſpring. Several of the ſmall birds, which are accuſed of injuring the bloſſoms of fruit-trees, do not injure them intentionally, but only accidentally in hunting after the above-named noxious little animals.

Theſe however do not excluſively belong to the Apple tree; but there is an extremely minute inſect of the cochineal tribe, which has lately appeared on the Apple trees near London, and has done incredible damage to them. Small downy ſpots appear on the ſtems and branches of the trees, each of which covers a multitude of theſe inſects, which are attached to the bark by their ſuckers, and fed by its juices. The trees on which they abound appear like tender exotics, the points of whoſe branches have been killed by the preceding winter. The inſects were firſt obſerved about Kennington in the year 1788, and were ſaid to have been imported from France. They have ſince gradually extended themſelves, and no means of deſtroying them have been yet diſcovered. It is the opinion of the moſt experienced nurſerymen round London, that all the Apple trees in that neighbourhood will be deſtroyed in a few years, if the inſects increaſe as rapidly as they have lately done.

The bloſſoms of the Apple appear alſo to fail not unfrequently from the want of impregnation, when the weather is unuſually hot and dry, or when cold winds prevail; the farina withering and dying on the anthers in ſuch ſeaſons. In each of theſe caſes, thoſe trees are always moſt productive, which having had the good fortune to eſcape the defolating hand of the prunet, are moderately full of wood, and capable of affording their bloſſoms ſome protection from froſt and cold winds, or exceſſive heat. Not that judicious pruning is to be reprobated, on the contrary it ought very frequently to be done; but every Apple tree ought to retain much of the cloſe branchy growth which nature gives it. The pruning-knife may however be uſed with ſome degree of freedom on young trees, for the branches of theſe ſoon repair any breaches which may be made in them; but if an old tree, or one which has ceaſed to grow larger, be ſo thinned as to admit a free current of air through it, the tree is ruined for ever. It has been ſuppoſed that the fruit, which ſtands expoſed to the ſun and air on the outſides of the branches, is alone capable of making fine Cider, but experience by no means juſtifies this concluſion[a].

[a] Culture of the Apple and Pear, 36 to 92.

Mr Bucknall is nearly of the ſame opinion with Mr. Knight reſpecting *Blight*. He ſuppoſes, that whatever has a tendency to prevent the due impregnation of the bloſſoms, or injure the foliage of the tree, ill in a certain degree cauſe blight. Some imagine that inſects are brought over in thick hazy clouds but they do not come over with winds from the continent, but are bred at home from eggs depoſite about the tree in ſummer and autumn. And reſpecting cold, it is not ſo much that which does the miſchief, as an alternate ſucceſſion of cold and heat. Cold cider-water, or land ſprings ſtunt the tree, and cauſe blight. Long drought, with drying winds, injure the ſaps, ſo that it performs its office imperfectly. Other cauſes may predispoſe the tree to blight, as an overabundant crop the preceding year, a want of free circulation of air, &c. but inſects for the moſt part produce the miſchief.

Asa remedy to this diſeaſe, Mr. Bucknall principally recommends cleanlineſs. Should the trees be old, ays he, in a declining ſtate of health, or the branches covered with rotten bark, moſs, &c. under which inſects may depoſit their eggs, ſwarms of depredators will iſſue forth to deſtroy the weakly foliage and bloſſoms. On the contrary, where trees are clean and in health, inſects are not ſo numerous, neither are they capable of being ſo deſtructive: for ſhould they even devour part of the opening buds and leaves, a healthy tree will have ſufficient ſtrength to produce at leſt a ſlight crop of fruit. For cleanſing trees from inſects oil has a good effect, or oil mixed with a little ſulphur or tobacco duſt, or bitter aloes, to give he oil the conſiſtence of a thin paint; or waſhing them well with ſoap-ſuds will anſwer the purpoſe[1]. For further particulars on this ſubject, ſee the articles BLIGHT and ORCHARD.

6. The Chineſe Apple tree, though perfectly hardy, ſhould be planted in a ſheltered ſituation; it is uſually increaſed by grafting it on the Crab ſtock[2].

9. The Virginian Crab tree with ſweet flowers is alſo increaſed by grafting or budding on the common Crab; but it is ſomewhat tender whilſt young, and therefore ſhould be planted in a warm ſituation.

12. The Portugal Quince is the moſt valuable, the pulp of it turning to a fine purple when ſtewed or baked, and becoming much ſofter and leſs auſtere than the others, is much better for making marmalade.

They are all eaſily propagated either by layers, ſuckers, or cuttings, which muſt be planted in a moiſt ſoil. Thoſe raiſed from ſuckers are ſeldom ſo well rooted as thoſe which are obtained from cuttings or layers, and are ſubject to produce ſuckers again in greater plenty, which is not ſo proper for fruit-bearing trees. The cuttings ſhould be planted early in the autumn, and in very dry weather muſt be often watered to encourage their rooting. The ſecond year after they ſhould be removed into a nurſery at three feet diſtance row from row, and one foot aſunder in the rows, where they muſt be managed as was directed for Apples. In two or three years time theſe trees will be fit to tranſplant, where they are to remain, which ſhould be either by the ſide of a ditch, river, or in ſome other moiſt place, where they will produce a greater plenty, and much larger fruit than in a dry ſoil; though thoſe in a dry ſoil will be better taſted, and earlier ripe. Theſe trees require very little pruning; the chief thing to be obſerved is, to keep their ſtems clear from ſuckers, and to cut off ſuch branches as croſs each other; likewiſe all upright luxuriant ſhoots from the middle of the tree ſhould be taken entirely out, that the head may not be too much crowded with wood, which is of ill conſequence to all ſorts of fruit-trees. They may alſo be propagated by budding or grafting upon ſtocks raiſed by cuttings, ſo that the beſt ſorts may be cultivated in greater plenty this way, than by any other method: and theſe trees will bear fruit much ſooner, and be more fruitful than thoſe which come from ſuckers or layers.

Theſe are alſo in great eſteem for ſtocks to graft and bud Pears on, which for ſummer and autumn fruits are a great improvement to them, eſpecially thoſe deſigned for walls and eſpaliers; for the trees upon theſe ſtocks do not ſhoot ſo vigorouſly as thoſe upon free ſtocks, and therefore may be kept in leſs compaſs, and are ſooner diſpoſed to bear fruit: but hard winter fruits do not ſucceed ſo well upon theſe ſtocks, their fruit being very ſubject to crack, and are commonly ſtony, eſpecially all the breaking Pears; therefore theſe ſtocks are only proper for the melting Pears, and for a moiſt ſoil. The beſt ſtocks are thoſe which are raiſed from cuttings or layers.

As the Pear will take upon the Quince by grafting or budding, and ſo vice verſa, we may conclude there is a near alliance between them; but neither of theſe will take upon the Apple, nor that upon either of theſe.
